The recent announcements in these columns with regard to the intention of the Allis-Chalmers Company to enter the field of heavy electrical machinery, as well as to develop the production of steam turbines, hydraulic turbines, gas engines, etc., in addition to its other well-known and standard lines of prime-movers, has been noted with the greatest interest by every one throughout the country occupied in electric light, power and traction. It would appear, however, that the Allis-Chalmers management is by no means at the end of the radical and decisive moves which it is to make under the new régime just entered upon, for as we go to press other developments are announced or rumored.

One of the most important events within the past few days has been the conclusion of an alliance between the Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Some time ago the Bullock Company secured a heavy contract for the equipment of the new Allis-Chalmers shops in the vicinity of Milwaukee, an event which may possibly have led up to the present deal owing to the satisfactory results obtained with the apparatus under test. Be this as it may, it now appears that the Bullock Electric Manufacturing Company, of Cincinnati, which is a New Jersey corporation, has been leased by a new Bullock Company organized under the laws of Ohio. This new corporation is one in which the Allis-Chalmers Company is financially interested as principal owner, and it takes over the business of its predecessor as a going concern. In this manner the Allis-Chalmers Company is at once able to fill orders ranging throughout the entire field of direct-current and alternating-current generating apparatus, Mr. B. A. Behrend, the engineer of the company, having added to the well-known standard line of direct-current motors and generators, rotary converters and some of the largest types of polyphase alternators and synchronous motors complying with the most exacting requirements in this country. It is also understood that the Bullock output now includes street railway motors, and that some of these have already been supplied to a road in Indiana. In this connection it is interesting to record that the new company has made a personal contract with President George Bullock, under whom the old company was vigorously and successfully built up, so that the administration of the company will remain unchanged, a contract having also been made with Mr. Neave for the retention of his services as vice-president. Some curiosity has been expressed in electrical circles as to the manner in which the Allis-Chalmers Company would be able to come at once into the market with electrical apparatus, instead of waiting one or two years to develop productions of its own, but it will be seen that this move provides for it a very satisfactory solution of the problem, enabling it to bid at once on whatever contract may be offered.

In connection with the affairs of the Allis-Chalmers Company, itself, and its own internal management, it would appear that some vital and important changes are being made. The first and most noteworthy of these is the resignation of President Chas. Allis, whose wife has been in seriously ill health and is now proceeding to the Mediterranean under medical advice for an indefinite stay. Mr. Allis felt that under these private conditions he could not possibly give all the attention to the business of the company that its affairs demanded at this juncture, and preferred, therefore, to take this step. His place in the management is to be filled by Mr. B. H. Warren, formerly vice-president of the Westinghouse Electric & Manufacturing Company and a man of distinguished engineering and business attainments, as well as of marked energy and executive ability. It is also understood that Mr. Edward D. Adams, the banker, who has been identified with the company since its organization a few years ago, has consented to take the chairmanship of the executive committee, this step involving the abolition of some of the previously existing committees and the concentration of a great deal of responsibility and power in his hands. Mr. Adams will, in fact, make his offices at the New York headquarters in the Empire Building and give a large amount of his time and thought to Allis-Chalmers affairs. No more striking proof could be given of the vigor with which the business of the company is to be pushed than these two events.

It has already been stated in these columns that Mr. John F. Kelly, formerly of the Stanley Company, has been made head of the electrical engineering department of the company, with Mr. William Stanley, Jr., as consulting electrical engineer; and to this may now be added the fact that Mr. Kelly has already begun his work and taken up affairs at the Allis-Chalmers offices. The company has other important plans and arrangements under contemplation, but the announcement of these above will suffice to keep the eyes of the electrical community fixed upon the action of the newcomer, whose entrance into the field must obviously be most profoundly felt.

In connection with Bullock Company affairs, we quote Mr. Joseph S. Neave, vice-president of the corporation, as follows: "The present Bullock Electric Manufacturing Company will remain intact. The same officers will be continued, and also the same management. The old company is incorporated according to the laws of New Jersey. There will be another Bullock Electric Manufacturing Company formed according to the laws of Ohio. This will be the leasing company of the plant, and this company will run the Bullock plant as it is run at the present time. In fact, the Bullock Electric Electric Manufacturing Company and the Allis-Chalmers plants will be run as if they were one concern. The Allis-Chalmers Company guarantees to pay the 6 per cent. dividend on the preferred stock of the Bullock Company. It goes further; the Allis-Chalmers Company agrees to pay 6 per cent. on the common stock of the old Bullock Electric Manufacturing Company for all the assets of the Bullock Electric Company that are over and above the valuation of the preferred stock.

"As an explanation of the payment of dividends for the common on the quick assets of the company, it might be stated that the preferred stock of the present Bullock Company amounts to $1,100,000, and the common to $1,000,000. Thus, after the valuation of the plant has covered the preferred stock and there should be, for instance, $500,000 of what is termed quick assets over, the Allis-Chalmers Company guarantees, during the life of the lease, 6 per cent. on this amount for the Bullock common stock.

"Besides the payment of these dividends," continued Mr. Neave, "the Allis-Chalmers Company agrees to divide the profits of the concern between the new company and the common stock of the old company. This will tend to make the earning power of the common stock of the old company a great deal more than it is at the present time.

"As a result of this deal with the Allis-Chalmers Company, the present capacity of the Bullock electrical works is to be enlarged. The first thing that will be done will be to erect another large shop, with an area of 40,000 sq. ft., where motors for street cars will be manufactured. This will mean the employment of about 400 more hands. It is the intention of the new leasing company to enter actively into the street car equipment field. The lease is for 25 years with the privilege of renewal for another 25 years on the same terms. It is my opinion that when the plants that are now under way have been completed the Bullock electrical works will give employment to from 2,000 to 3,000 hands.

"While the papers in the deal have all been signed, the deal will not go legally into effect until after the stockholders of the present Bullock Electric Company have had their special meeting at Jersey City on Wednesday, March 16. Mr. George Bullock and myself will be at that meeting with the proxies to ratify the deal."

Telegraph Between Irkutsk and Pekin.

The Commercial Cable Company is advised that by an arrangement with the Great Northern Telegraph Company, the direct wire between Irkutsk, Siberia, and Pekin, China, is open for the interchange of business.

Trolley Beats Steam.

A special dispatch to the daily press from Kansas City, Mo., of March 4, says: "In a two-and-a-half-mile race between a Missouri Pacific express train and an electric car on the Leavenworth-Kansas City line last night, the railroad locomotive was beaten by two car lengths. The roads are parallel, and the electric line manager waited with a party of road officials at the beginning of the stretch. The railway engineer put on all steam, and the cars ran even until the last quarter of a mile, when the electric car slowly forged ahead, and bounded across the finish line at fifty miles an hour, winner by 120 feet." We do not see that this proves anything in particular, or of any value, although it may be a good "ad" for the local trolley service.

The Electric Power and Transmission System of Schaffhausen, Switzerland.—I.

ONE of the most remarkable of Switzerland's hydro-electric plants is that located at the famous Schaffhausen Falls on the headwaters of the Rhine in northern Switzerland. As early as 1863 Heinrich Moser built a water power plant for the municipality of Schaffhausen. In this plant three turbines aggregating 700 hp were installed, and power was delivered to Schaffhausen, three miles distant by wire-rope transmission, the ropes running over sheaves supported on piers erected several hundred feet apart. In 1887 a second power house was erected below the first one and five 300-hp turbines were installed.

In 1891 the Oerlikon Company furnished the Schaffhausen Insane Asylum with a lighting dynamo arranged to be driven by a branch of the rope system. A citizens' committee was formed at the same time to decide whether the old system should be repaired and retained or electric transmission installed. After extended study the municipality closed a contract with the Oerlikon Company, in 1896, for a complete electric generating and transmission system. This order called for two 2,000-volt alternators connected by bevel gearing to two 300-hp turbines rented by the municipality from the Schaffhausen Water Works Company. Current from these generators is transmitted by buried cables to the several transformers in the town. Outside the town limits wires carrying secondary voltages only are strung on wooden poles.

By December 31, 1897, current was being furnished to 26 hp in motors and for arc and incandescent lamps equivalent to 86,940 cp. The electrical machinery cost $23,493.94 (121,730.24 francs). During the first year power was produced at the cost of 11.14 cents per kw-hour. In 1898 the municipality of Schaffhausen purchased for $123,520 (640,000 francs) the two power plants and dam owned by the Schaffhausen Water Works Company and immediately set about to install a completely electrified system. The following changes were to be made by the Oerlikon Company: Replacing the three old turbines in the upper station by new ones suitable for direct connection to generators, and adding another turbine and generator to the lower station, making in all for that station five turbines, including three turbo-generator sets, one of the latter being a reserve unit.

The rebuilding of the upper station was begun in March, 1900. Before the old structure was torn down the machinery was temporarily enclosed in a wooden building erected inside of the old one. The new station is of steel skeleton construction and has a roof made of wood and cement. The new turbines and alternators were placed in service in January, 1901. During the same year two Oerlikon rotary converters for the Neuhausen-Schaffhausen Street Railway were also placed in this station.

The new equipment has given such satisfaction that the municipality is seriously considering the replacement of the old turbines in the lower station by new ones, and later purchasing and modernizing the remaining power plant of the Schaffhausen Water Works Company.

This station is 460 ft. below the upper one and is connected to the right shore of the Rhine by an iron bridge, which is also used to carry the high-tension cables. The pit is built of concrete, and the rest of the building of brick. In the western part of the machinery room a wire partition encloses the power unit leased by the Schaffhausen Worsted Works.

The water flow to the five turbines is regulated through iron double-turning doors from the floor of the machinery room. The northern half of the eastern part of the machine room is served by a six-ton crane, and the southern half by a five-ton crane. Five 14-amp. arc lamps and forty 25-cp incandescent lamps are used to light the station.

The power equipment of the Schaffhausen Worsted Works consists of two Jonval turbines built by J. J. Rieter, two Oerlikon dynamos and Oerlikon controlling apparatus.

FIG. 1.—GENERAL VIEW OF BOTH POWER HOUSES ON THE RHINE AT SCHAFFHAUSEN.

With a fall varying from 14 ft. to 16 ft. and 2,000 to 2,250 gallons, the turbines give 350 hp at 60 r.p.m. The turbines are fitted with two concentric wheels, both being used at high water and the outside one only at low water periods. When both wheels are used the hand cover on the inner one is removed. The outside diameter of the turbine is 11 ft., the inner diameter 6 ft. (1.79 m.). The leading wheels, which carry a forged-iron suction casing at the lower end, have each 40 cast-iron vanes 1½ in. thick. The running wheels, the lower parts of which are 1.4 above lowest water, have each 42 vanes ½ in. thick.

Power is transmitted from the turbines to the dynamos by bevel gearing and rope shafts, which are 13 ft. in diameter, and have 10 grooves for carrying the rope drive, consisting of hemp ropes, each 2 in. in diameter.

The two Oerlikon direct-current generators used were built in 1890; they have six poles and a capacity each of 300 hp, 700 to 750 volts, at 200 r.p.m.

The controlling apparatus for these machines is mounted on an iron-supported switchboard having a marble front, the other sides being covered with perforated tin. There is one double-pole switch, one ammeter and one voltmeter for each machine. The outgoing cables can be cut out through two double-pole switches. During lightning storms the current is cut off and the overhead cables are grounded through another double-pole switch. Two shunt regulators and two primary current resistances are used in starting the dynamos. The four outgoing cables are protected by four lightning arresters, and are divided into two pairs, each of which is connected in parallel.

The eastern part of the machine room contains the three hydro-electric sets, two of which generate single-phase current and the third or reserve unit either single-phase or polyphase current. The turbines are of Jonval type and were built by Escher, Wyss & Co., of Zurich. The two turbines for running the single-phase machines have vertical shafts and are built for a head of 15 ft. and a flow of 1,700 second-gallons. Their speed is 48 r.p.m.

At high water the head decreases to 11 ft., and it is, therefore, necessary to increase the flow to 2,250 second-gallons to get the required power. This is accomplished by using two concentric wheels having respectively 36 and 24 vanes. The outside wheel only is used during low-water periods, but both wheels are required at high water. It may be mentioned in this connection that these turbines were not originally intended for electric service.

Power is transmitted from the vertical shafts by horizontal intermediate shafting and head gearing, as it was found inadvisable to couple the turbine and generators on the same shaft, owing to the low peripheral speed of the turbines and the limited space between them.

The 300-hp. single-phase alternators are of the inductor type and at 167 r.p.m. generate 100 amp. at 2,000 volts and 50 cycles. The efficiency of these machines is 92 per cent. at full load and 87 per cent. at half load.

The inductor has no wire windings, but carries 2 x 18 pole shoes made of an alloy of tin and iron. These poles are arranged in pairs lying in the same axis for generating the induction in the armature windings and thus forming the required magnetic yoke.

The inductor has a diameter of 8.75 ft. and revolves inside the armature housing, the inside diameter of which is 8.7 ft. In the armature housing 2 x 36 armature spools are set in grooves. These spools are thoroughly insulated and consist of seven windings made of copper strips 25 mm. broad and 1.4 mm. thick. The spools of both armature halves are connected in series and are wound in the same direction. The armature housing can be so manipulated as to permit the ready inspection or substitution of all armature parts. The exciter spool is mounted between the two armature halves. It consists of a massive casing containing 305 windings of copper wire 7 mm. thick.

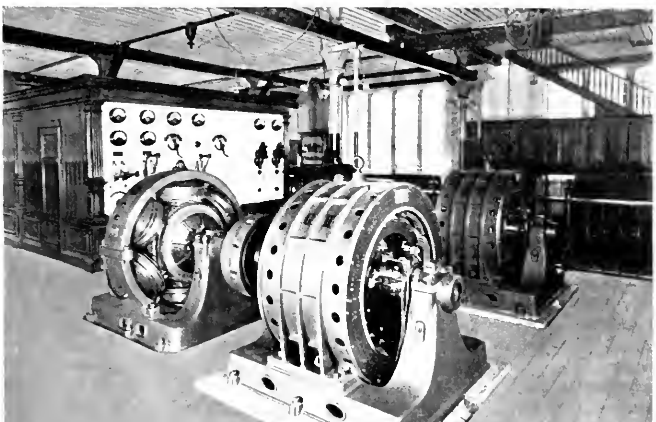

FIG. 2.—VIEW OF INTERIOR OF LOWER POWER STATION, SCHAFFHAUSEN.

The base plate of each exciter is cast solid, with the corresponding alternator. The exciters are all of double-pole type, giving at 420 r.p.m. 120 amp. at 50 volts. Each is driven by four ropes, each 15 mm. in diameter from a rope sheave mounted on the shaft of the corresponding generator. If necessary, one of these machines can be used to excite two alternators. The voltage of the alternators is regulated in the excited circuits.

The third generator has a rated capacity of 350 hp and is built for single-phase and polyphase work. As a single-phase machine it gives at 167 r.p.m. 210 kilovolt-amperes at 2,000 volts, and as a polyphase alternator 300 kilovolt-amperes at same speed and voltage. The frequency in each case is 50 cycles. The general arrangements of this machine are similar to those of the other two just mentioned, with which it must be operated in parallel. The armature is divided into two parts connected in series, each part having 108 grooves and 54 spools. Each spool is made up of 18 windings, each winding consisting of two parallel wires 3/16 in. in diameter. The exciter spool consists of 300 windings of insulated copper strips measuring 1 x 60 mm. The insulation between each winding is composed of asbestos bands about 1/64 in. thick.

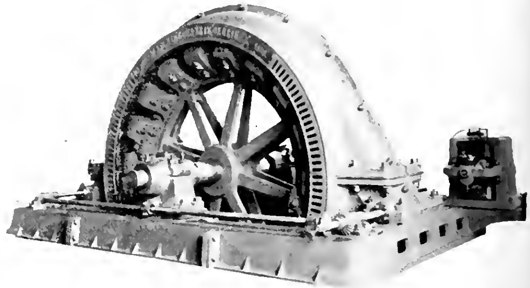

FIG. 3.—300-HP SINGLE-PHASE ALTERNATOR.

The inductor and armature housing are like those of the 300-hp machines described. The exciter is also the same as the others. The armature has 54 grooves, each of which serves to take four leads, each consisting of four parallel wires of 2.2 to 2.8 mm. diameter. The two parallel-connected magnet spools consist of 1,200 windings of wire measuring 1.6 mm. to 2 mm. in diameter.

All of the controlling apparatus is enclosed in several wooden housings, with marble fronts. These several housings and boards were built at different times as the station developed. Owing to the number of machines to be looked after, the designers concluded that they could be better handled if controlled from separate and nearby switchboards rather than from a central and more distant board.

The single-phase switchboard includes also instruments for the third generator when used for single-phase. The board is divided into seven panels. Each of these panels contains the following instruments for each generator: Ammeter, voltmeter, hand switch, lever, double-pole switch, phase lamp for paralleling the generators, hand wheel for regulating, and carbon-contact circuit-breaker. The two regular single-phase machines can be regulated simultaneously by a Gall's chain. The fourth panel carries an ammeter for measuring all the single-phase current, a constant voltmeter with optical and acoustic signals, voltmeter switch and two double-pole switches for paralleling two alternators.

There is a separate panel for each exciter furnished with ammeter, voltmeter, hand lever for double-pole switch and for carbon-contact circuit-breaker, as well as hand wheel for shunt regulation. The board is also furnished with a large voltmeter, which indicates the voltage on the city lighting lines, and thus enables the station attendant to keep the voltage at the proper point. The housing also contains a number of other controlling devices.

The second switchboard serves as a center for the control of the third generator when used for polyphase working, and also for the polyphase current transmitted from the upper works. This board consists of four panels. The one for the reserve generator carries a voltmeter, ammeter, regulating wheel and levers for three-pole switch and carbon-contact circuit-breaker. The next panel controls the polyphase current from the upper station and carries a voltmeter, ammeter and lever of three-pole switch. The other panels carry instruments for measuring all the current in circuit. Other controlling apparatus is mounted inside the switchboard housing.

The southeast portion of the station contains two motor-generator sets for railroad service. One of these sets is always held in reserve. The motors receive current either from the upper station or from the reserve generator in the lower station.

The twelve-pole polyphase motors of these sets are built for 150 hp at 490 r.p.m., using 2,000 volts at 50 p.p.s. The stator has 144 slots, each of which receives 8 leads. Each wire is 4.8 mm. in diameter. The rotor has 180 slots, taking 4 naked wires 4 mm. in diameter.

Each motor is connected to the corresponding direct-current generator by a flexible coupling. Each dynamo generates 182 amp. at 550 volts. The armature contains 200 slots, each containing two spool halves, each consisting of three parallel wires 3.6 to 4.2 mm. in diameter.

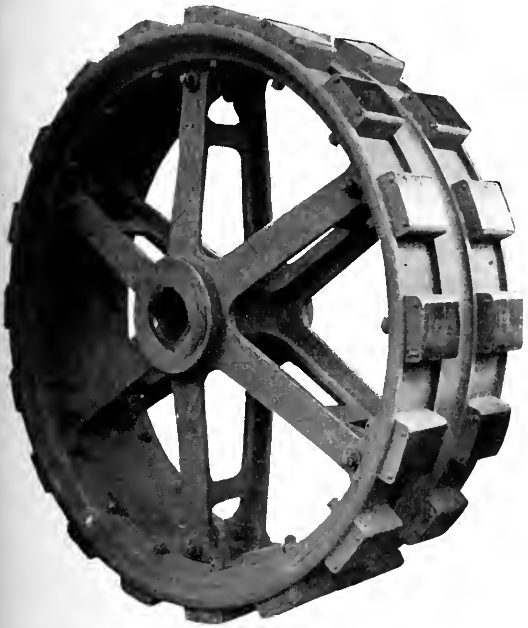

FIG. 4.—INDUCTOR FOR ALTERNATOR.

The field has six spools connected in series and containing 3,300 turns of 1.6 to 2 mm. wire shunt winding and 3.5 turns of 1.5 x 100 mm. copper-tin compound winding.

This portion of the building contains a switchboard for control of the motor-generator sets and of the polyphase current from the upper works. The latter is transmitted underground by two cables of 3 x 60 mm. cross-section. Besides switches for controlling these cables the board contains an ammeter for each motor, three-pole circuit-breaker, voltmeter, wattmeter and safety devices. The direct-current part of the board contains for each generator an ammeter, voltmeter, two-pole switch and regulator. A two-pole switch is used to connect the generators and buffer battery in parallel. Two double-pole switches are used to permit the generators to run either as shunt or compound machines, the first being the case when the generators are in parallel with the battery and the second when the battery is out of service. Another double-pole switch serves to connect the battery halves in parallel or series. An ammeter and voltmeter are used to measure the current generated. Each of the outgoing feeders is controlled by an ammeter, wattmeter and a switch having a device for testing for short-circuits. Lightning arresters and other devices are placed in the housing.

UPPER POWER STATION.

This station is built of iron and brick with a roof of wood and cement. The interior of the building contains a 10-ton crane operated by hand. The station is illuminated by two 14-amp. series arc lamps and 16 incandescent lamps.

One of the turbo-generator sets is owned by the Schaffhausen Cord Works, which, like the Schaffhausen Worsted Works, leases power from the city. Two turbo-generator sets are used for general distribution. The generators are all connected to the turbines by gearing. The latter two turbines were built by Escher, Wyss & Co., and the first mentioned by J. J. Rieter & Co., each for a capacity of 350 hp at 60 r.p.m. and a flow varying from 1,950 to 2,100 second-gallons.

The first-mentioned turbine is of the Jonval type and is connected to a 350-hp. three-phase generator, which at 170 r.p.m. gives 420 amp. per phase, 400 volts and 51 cycles. This generator is directly coupled to a 4-pole exciter, giving at 170 r.p.m. 150 amp. at 40 volts. A separate switchboard is used for this private installation.

The two other turbines are of Francis type and run at 60 r.p.m. The generators coupled to them are of the same size and type as the one used with the Worsted Works turbine. The exciters are direct-coupled and are similar to the one last described.

The switchboard for the control of these two generators and exciters consists of an iron framework having a white marble front. The exciter panel carries for each exciter one ammeter, voltmeter, double-pole switch lever and regulating hand wheel. Each generator panel carries an ammeter, voltmeter, wattmeter, lever for operating high-tension switch, handle for carbon circuit-breaker and hand wheel for regulating. The regulating wheels of the generators are connected by a Gall's chain. The general panel carries an ammeter and voltmeter for measuring the power sent to the lower station and a contact voltmeter with relays and acoustic signal. The panel housing contains transformers, resistances, etc.

Favoring Submarine Boats.

A report has been received at the War Department from a board of artillery officers, composed of Major Arthur Murray, Capt. C. J. Bailey and Capt. C. F. Parker, in regard to the recent test of the submarine boat *Protector* at Fort Adams, Mass. The report has been referred to the General Staff for consideration. The board recommends, in consequence of its conclusions, that five of these boats be purchased for use in submarine defence, as follows: One for the school of submarine defence, for experimental work; one for the eastern entrance of Long Island Sound, one for the entrance of Chesapeake Bay, one for San Francisco harbor and one for Puget Sound. The report says:

"The board believes that this type of submarine boat is a most valuable auxiliary to the fixed mine defence, and in cases where channels cannot be mined owing to depth, rough water, swift tides or width of channels, it will give the nearest approach to absolute protection now known to the board. The boat can lie for an indefinite time adjacent to the point to be defended in either cruising, awash or submerged condition, by its anchors or on the bottom ready for instant use, and practically independent of the state of the water and in telephonic connection with the shore, or can patrol a mined or unmined channel invisible to the enemy and able to discharge its torpedoes at all times. In narrow channels the boat or boats would have a fixed position with a telephone cable buoyed or anchored at the bottom. In wide channels they would patrol or lie in mid channel or where they could readily meet approaching vessels. With picket or scout boat, outside the mine field, or even at extreme range of gun fire, telephone communication can be sustained and information received and instructions sent for attacking approaching vessels.

"For an attack the boat shows great superiority over any existing means of attacking mine fields known to the board. It can run by any field, as installed at present, with but little or no danger from the explosion of any particular mine or from gun fire during the few seconds it exposes the sighting hood for observations and can attack at its pleasure vessels in the harbor. The board personally witnessed the ease with which cables can be grappled, raised and cut. While the boat is manœuvring on the bottom mine cables can be swept for, found and cut, or a diver can be sent out for that purpose. The board recommends consideration of the foregoing by the General Staff.

"The question of the use of the Whitehead torpedoes as part of the fixed mine defence, fired from tubes on shore, is now receiving consideration. Where channels are wide and water is swift this use of the Whitehead will be very limited. With boats of this type the Whitehead can, it is believed, be carried within certain effective range in all ordinary channels, and this alone will warrant the consideration asked for."

Petrus Peregrinus—Author of the Earliest Treatise on the Magnet, 1269.

BY BROTHER POTAMIAN, D.SC., LOND.
PROFESSOR OF PHYSICS IN MANHATTAN COLLEGE, NEW YORK.

THE magnetic lore of classic antiquity was scanty indeed, being limited to the attraction which the lodestone manifests for iron. Lucretius (99-55 B.C.), however, in his poetical dissertation on the magnet, contained in *De Rerum Naturo,* Book VI[1], recognizes magnetic repulsion and to some extent the magnetic field with its lines of force, for in verse 1040 he writes:

> Oft from the magnet, too, the steel recedes,
> Repelled by turns and re-attracted close.

And in 1042:

> And oft in brazen vessels, may we mark
> Ringlets of Samothrace, or fragments fine,
> Struck from the valid iron bounding high,
> When, close below, the magnet points its powers.

The poet Claudian (365-408 A.D.) wrote a short idyl on the attractive virtue of the lodestone and its symbolism; St. Augustine (354-430), in his work *De Civitate Dei,* records the fact that a lodestone, held under a silver plate, draws after it a scrap of iron lying on the plate. Abbot Neckam, the Augustinian (1157-1217), distinguishes between the properties of the two ends of the lodestone, and gives in his *De Utensilibus,* what is perhaps the earliest reference to the mariner's compass that we have. Albertus Magnus, the Dominican (1193-1280), in his treatise, *De Mineralibus,* enumerates different kinds of natural magnets and states some of the properties commonly attributed to them; the minstrel, Guyot de Provins, in a famous satirical poem, written about 1208, refers to the directive quality of the lodestone and its use in navigation, as do also Cardinal de Vitry in his *Historia Orientalis* (1215-1220); Brunetto Latini, poet, orator and philosopher, in his *Trésor de toutes Choses,* printed in Paris in 1260; Raymond Lully, the Enlightened Doctor, in his treatise, *De Contemplatione,* begun in 1272, and Guido Guinicelli, the poet-priest of Bologna, who died in 1276.

The authors of these learned works were too busy with their pen to find time to devote to the close and prolonged study of natural phenomena necessary for fruitful discovery, and so had to content themselves with recording and discussing in their tomes the scientific knowledge of their age without making any notable additions to it.

But this was not the case with such contemporaries of theirs, as Roger Bacon, the Franciscan, and his Gallic friend, Pierre de Maricourt, commonly called Petrus Peregrinus, the subject of the present notice, a man of academic culture and of a practical rather than speculative turn of mind. Of the early years of Peregrinus, nothing is known save that he studied, probably, at the University of Paris, and that he graduated with the highest scholastic honors. He owes his surname to the village of Maricourt, in Picardy, and the appellation Peregrinus, or Pilgrim, to his having visited the Holy Land as a member of one of the crusading expeditions of the time.

In 1269 we find him in the engineering corps of the French army then besieging Lucera, in southern Italy, which had revolted from the authority of its French master, Charles of Anjou. To Peregrinus was assigned the work of fortifying the camp and laying mines as well as of constructing engines for projecting stones and fire-balls into the beleaguered city.

It was in the midst of such warlike preoccupations that the idea seems to have occurred to him of devising a piece of mechanism to keep the astronomical sphere of Archimedes in uniform rotation for a definite time. In the course of his work over the new motor, Peregrinus was gradually led to consider the more fascinating problem of perpetual motion itself with the result that he showed, at least diagrammatically, and to his own evident satisfaction, how a wheel might be driven round forever by the power of magnetic attraction. "This is the first recorded contrivance of the kind," writes Dr. Park Benjamin, in his "Intellectual Rise in Electricity," "which came into the world and probably served a good purpose," p. 166. "It was the beginning of that arch-delusion in mechanics which ran for centuries parallel with the arch-delusion in chemistry and with consequences very similar," p. 168.

Elated over his imaginary success, Peregrinus hastened to inform a friend of his at home; and that his friend might the more readily comprehend the mechanism of the motor and the functions of its parts, he proceeds to set forth in a methodical manner all the properties of the lodestone, most of which he himself had discovered. It is a fortunate circumstance that this Picard friend of his was not a man learned in the sciences, otherwise we would probably never have had the remarkable exposition which Peregrinus gives of the phenomena and laws of magnetism. This letter of 3,500 words is the first great landmark in the domain of magnetic philosophy, the next being Gilbert's *De Magnete,* in 1600.

The letter was addressed to Sigerus de Foucaucourt, his "amicorum intimus," the dearest of friends. A more enlightened friend, however, than the knight of Foucaucourt was Roger Bacon, who

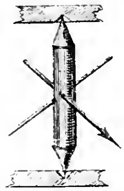

FIG. 1.—DOUBLE-PIVOTED NEEDLE OF PEREGRINUS, AFTER BERTELLI.

(*The magnet is arrow-shaped. The second needle is made of silver or copper, a non-magnetic substance; it was probably intended to be used as a pointer.*)

held Peregrinus in the very highest esteem, as the following glowing testimony shows: "There are but two perfect mathematicians," wrote the English monk, "John of London and Petrus de Maharne-Curia, a Picard." Further on in his *Opus Tertium,* Bacon thus appraises the merits of the Picard: "I know of only one person who deserves praise for his work in experimental philosophy, for he does not care for the discourses of men and their wordy warfare, but quietly and diligently pursues the works of wisdom. Therefore, what others grope after blindly, as bats in the evening twilight, this man contemplates in all their brilliancy because he is a master of experiment. Hence, he knows all natural science whether pertaining to medicine and alchemy, or to matters celestial and terrestrial. He has worked diligently in the smelting of ores as also in the working of minerals; he is thoroughly acquainted with all sorts of arms and implements used in military service and in hunting, besides which he is skilled in agriculture and in the measurement of lands. It is impossible to write a useful or correct treatise in experimental philosophy without mentioning this man's name. Moreover, he

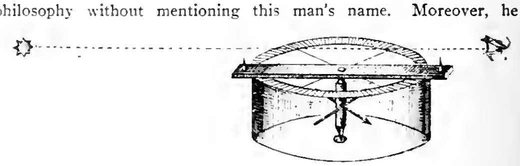

FIG. 2.—GRADUATED COMPASS OF PEREGRINUS, AFTER BERTELLI.

(*The Azimuth bar moves independently of the magnet, and carries a pair of terminal pins for sighting a star near the horizon.*)

pursues knowledge for its own sake; for if he wished to obtain royal favor he could easily find sovereigns who would honor and enrich him."

This last statement is worthy of the best utterances of the twentieth or any other century. Say what they will, the most ardent pleaders of our day for original work and laboratory methods cannot surpass the Franciscan monk of the thirteenth century, in his denunciation of mere book learning or in his advocacy of experiment and research, while in Peregrinus, the mediævalist, they have Bacon's impersonation of what a student of science ought to be. He was a hard worker, not a mere theorizer, preferring, Procrustean-like, to make theory fit the facts rather than facts the theory; he was a brilliant discoverer who knew at the same time how to use his discoveries for the benefit of mankind; he was a pioneer of science and a leader in the progress of the world.

An analysis of the "Epistola" shows that

[1] With very few exceptions all the works referred to in this notice will be found in the Wheeler Collection in the Library of the American Institute of Electrical Engineers.

(*a*) Peregrinus was the first to assign a definite position to the poles of a lodestone, and to give directions for determining which is north and which south;

(*b*) He proved that unlike poles attract each other, and that similar ones repel;

(*c*) He established by experiment that every fragment of a lodestone, however small, is a complete magnet, thus anticipating one of our fundamental laboratory illustrations of the molecular theory;

(*d*) He recognized that a pole of a magnet may neutralize a weaker one of the same name, and even reverse its polarity;

(*e*) He was the first to pivot a magnetized needle and surround it with a graduated circle, Figs. 1 and 2;[2]

(*f*) He determined the position of an object by its magnetic bearing as done to-day in compass surveying; and

(*g*) He introduced into his perpetual-motion machine, Fig. 3, the idea of a magnetic motor, a clever idea, indeed, for a thirteenth century engineer.

This rapid summary will serve to show that the letter of Peregrinus is one of great interest in physics as well as in navigation and geodesy. For nearly three centuries it lay unnoticed among the libraries of Europe, but it did not escape Gilbert, who makes frequent mention of it in his *De Magnete*, 1600; nor the illustrious

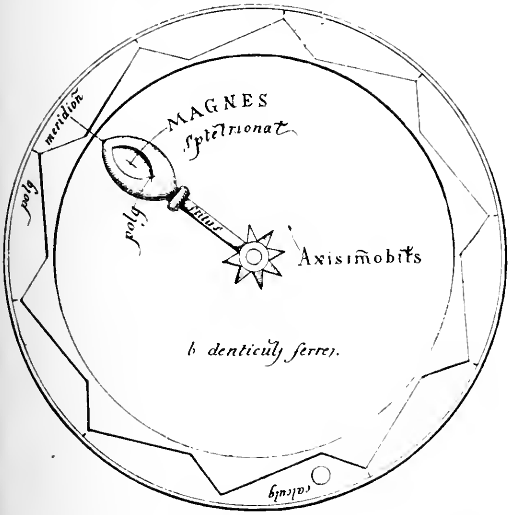

FIG. 3.—THE CONTINUOUSLY-MOVING WHEEL, OR MAGNETIC MOTOR, OF PEREGRINUS, AFTER GASSER.

Jesuit writers, Cabæus, who refers to it in his *Philosophia Magnetica*, 1629, and Kircher, who quotes from it in his *De Arte Magnetica*, 1641; it was well known to Jean Taisnier, the Belgian plagiarist, who transferred a great part of it verbatim to the pages of his *De Natura Magnetis*, 1562, without a word of acknowledgement. By this piece of fraud Taisnier acquired considerable celebrity, a fact that goes to show the meritorious character of the work which he unscrupulously copied.

This memorable letter is divided into two parts: the first contains ten chapters on the general properties of the lodestone; the second has but three chapters, and shows how the author proposed to use a lodestone for the purpose of producing continuous rotation.

There are many manuscript copies of the letter in European libraries: the Bodleian has six; the Vatican, two; Trinity College, Dublin, one; the Bibliothèque Nationale, Paris, one; Leyden, Geneva and Turin, one each. The Leyden MS. has acquired special notoriety from a passage which appears near the end of it in which reference is made to magnetic declination and its value given; but Prof. W. Wenkebach, of The Hague, has shown[3] that the lines are spurious, having been interpolated in the manuscript in the early part of the sixteenth century.

The Leyden manuscript has also led some writers to believe in a fictitious author of the letter, one Peter Adsiger, or Petrus Adsigerus.

[2] It is probable that Flavio Gioja, some fifty years later added the compass-card and attached it to the magnet.
[3] Annali di Matematica Pura ed Applicata, 1865.

As said above, Sigerus was the name of his countryman, to whom Peregrinus addressed his letter, the *Epistola ad Sigerum*, from the trenches at Lucera, in August, 1269.

The first printed edition, now very rare, was prepared by Achilles Gasser, a physician of Lindau, a man well versed in mathematics, astronomy, history and philosophy. The work was printed in Augsburg in 1558. A copy of this early print is among the treasures of the Wheeler collection in the library of the American Institute of Electrical Engineers, New York. It was from this text that the translation which will follow this introductory notice was made.

Besides the Latin edition of Gasser, 1558, there is also that of Bertelli, 1868, and Hellmann, 1898. Bertelli's is an exhaustive and learned work in which the Barnabite monk, sometimes called by mistake, Barnabita, instead of Bertelli, collates and compares the readings of the two Vatican codices with other texts, adding copious references and explanatory notes. It appeared in the *Bulletino di Biografia e di Storia delle Scienze Mathematiche e Fisiche* for 1868.

Of translations, we have that which Richard Eden made from Taisnier's pirated extracts, the first dated edition appearing in 1579. Cavallo's *Treatise on Magnetism*, 1800, also contains some of the more remarkable passages; Libri's *Histoire des Mathématiques*, 1838, has a full version made from an original manuscript in the Bibliothèque Nationale. The only complete English translation that we have, appeared in 1902 from the scholarly pen of Prof. Silvanus P. Thompson, of London. It is an *édition de luxe* beautifully rubricated, but limited to 250 copies. The translation was based on the texts of Gasser and Hellmann, amended by reference to a manuscript in the author's possession, dated 1391. We are informed that Mr. Fleury P. Mottelay, of New York, the learned translator of Gilbert's *De Magnete*, possesses a manuscript version by Prof. Peirce, of Harvard, of the Paris codex, of which he made a careful study in an endeavor to decipher the illegible parts.

Predetermination of Transformer Regulation.

BY EMERSON G. REED.

THE predetermination of the regulation of a given transformer from its design is a very simple matter in the case of a non-inductive load. With such a load the lost voltage, neglecting the effects of hysteresis and eddy currents, is the resistance drop in primary and secondary winding. Due to the effects of magnetic leakage, that is leakage of lines of force between primary and secondary winding, it becomes a more difficult matter to predetermine the regulation with an inductive or capacity load. The amount of this leakage depends upon the shape of the transformer, the relative

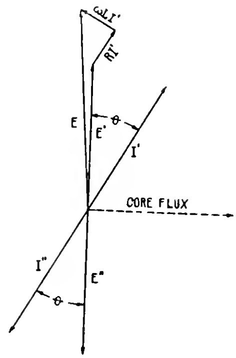

FIG. 1.—TRANSFORMER REGULATION.

position of primary and secondary windings, the number of primary turns and upon the current in the coils.

It is the object of this article to give some examples of a method of calculating the effects of this leakage which the writer has used with success in a large number of cases.

It can be shown that the effect of this magnetic leakage is equivalent to an outside inductance, L, connected in series with the primary winding.

Imagine a transformer (Fig. 1) whose secondary e.m.f. is E'', supplying current I'' through such a load that the angle of lag between

E'' and I'' is θ. The angle between I' and E', the primary counterparts of E'' and I'', is also θ.

The primary impressed e.m.f., E, is made up of three components, the part E', the resistance drop $R\,I'$, and the part $\omega\,L\,I'$ lost in the inductance L. The quantity R may be called the equivalent primary resistance of the transformer and in like manner the quantity L may be called the equivalent primary inductance ($\omega = 2\pi\ f$, f being the frequency of the alternating current).

We may reconstruct the part of Fig. 1, in which we are particularly interested, to larger scale and study it in detail. (See Fig. 2.)

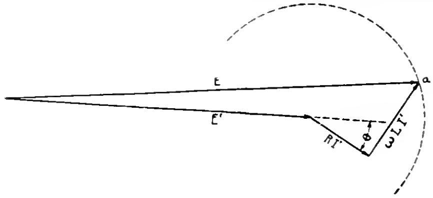

FIG. 2.—TRANSFORMER REGULATION.

The point a may take any position on the dotted circle depending on the value of the angle θ. The part in which we are now interested is the calculation of the quantity L.

It can be shown that

$$L = 4\pi\,n^2\,\frac{\lambda}{l}\left[\frac{X+Y}{3}+g\right]$$

(See Franklin & Williamson's "Alternating Currents" and J. P. Jackson's "Alternating-Current Machinery.")

In this equation, n is the number of primary turns and the quantities X, Y, g and λ are shown in Fig. 3. When the quantities are

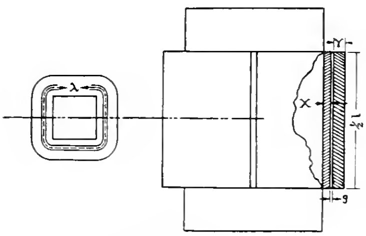

FIG. 3.—TRANSFORMER REGULATION.

given in c.g.s. units, L will be expressed in centimeters, which, when divided by 10^9, gives henrys.

When L has been determined, it is an easy matter to work out graphically from Fig. 2 the value of E, and from thence the regulation. It is more accurate to determine analytically the value of E, as the quantity $E\,I'$ and $\omega\,L\,I'$ are small compared to E'.

To check the calculated results after the transformer has been built, the secondary may be short-circuited and voltage applied to the primary until full lead current flows through the secondary. The primary applied or the impedance voltage is the vector sum of $R\,I'$ and $\omega\,L\,I'$.

The preceding table gives the calculated data on a line of commercial core-type transformers. The calculated values of impedance voltage were found to correspond very closely to the experimental values.

Calculation of the Equivalent Ampere-Turns of Windings for Single and Polyphase Currents.—I.

By C. F. Guilbert.

The calculation of the mean ampere-turns produced by alternating currents in the armature of an alternator, or in the primary or secondary windings of an asynchronous motor, has been treated by several authors, and for the first time by Prof. Blondel in his interesting study on "rotary fields."[1]

Unfortunately, Prof. Blondel, as well as most writers who have followed him, gives only the result of calculations in the form of tabulations, and then only for the case of windings where the slots of the same phase are placed, for each pole, one following the other. Such cases we shall designate as separate phase windings. Though this type of winding is equally applicable to coils and bars, at times it is desirable to utilize in an alternator with a revolving armature, a direct-current winding. This is particularly true in the case of self-exciting alternators, and sometimes, notwithstanding the recognized inherent defects of this kind of winding, for the rotor and stator of asynchronous motors. Such direct-current windings we shall designate as superposed phase windings. The study printed in these columns in issues of October, November and December, 1902, on the reaction of alternator armatures, led to a general formula admitting of the calculation of the equivalent m.m.f. per pole of a single-phase or polyphase winding, of the separate phase type in the latter case. This formula includes the case treated by Prof. Blondel.

The determination of the equivalent m.m.f. of an elementary coil of a winding, which was the starting point of the study just mentioned, also enables the establishment of formulas relating to the case of superposed windings. The present object is to deduce formulas of simple form for the cases apt to occur. First, however, we shall give briefly and in a manner much more simple than in the above-mentioned articles, the method of finding an expression for the equivalent m.m.f. of any elementary coil of an alternating-current winding, limiting it, however, to the case of asynchronous motors—that is, to the case in which the width of the flux is always equal to the polar step.

EQUIVALENT M.M.F. OF AN ELEMENTARY COIL.

To determine the equivalent m.m.f. of a coil of N turns during a half period—that is to say, the continuous m.m.f. producing a flux equal to the useful turning flux—we will calculate the m.m.f. of the field for any point of the armature (supposed to have a speed corresponding to that of synchronism) for all the relative positions having a half period; then the mean value of that m.m.f. at the point considered, and finally the mean m.m.f. for all the points comprised in the width of a polar step, a.

$$\text{Let } i = I_0 \cos\frac{\pi x}{a} \qquad x = \frac{2at}{T}$$

be the expression for the assumed maximum current at the moment when the axes of the field and armature poles coincide, I_0 being the maximum value of the current $I_0' = I\sqrt{2}$ for an output of current I, and x the variable phase displacement, during rotation, of the axis of one field pole with respect to the corresponding armature pole. Consider (Fig. 1) a point A of the armature at a distance y from the pole axis, and the variation at that point of the m.m.f. during a half period.

Let b be the peripheral length of a coil between the axes of two slots containing it. So long as the displacement is less than $\frac{b}{2} - y$, the point remains under the inducing coil and the m.m.f. decreases

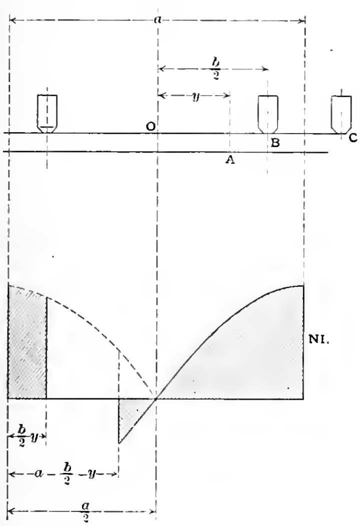
[1] A. Blondel. Quelques propriétés générales des champs magnétiques tournants. *Eclairage Electrique*, tome IV., page 24; 1895.

simply as $\cos\frac{\pi x}{a}$ (Fig. 2). For $x = \frac{b}{2} - y$, the line of force passing the given point does not leave the inducing coil, the m.m.f. falls to zero and remains so until the displacement becomes greater than

$$O B + B C = \frac{b}{2} - y + a = a - y - \frac{b}{2}$$

From this moment the m.m.f. changes sign, since it passes under the elementary coil of the following field pole. It diminishes in absolute value to zero for a displacement equal to $\frac{a}{2}$, then increases again, after having changed sign with the current, until the end of the half period.

We will obtain the mean value of the m.m.f. at the given point by



FIGS. I AND 2.—CALCULATION OF AMPERE-TURNS.

referring to the hatched surface and taking account of the negative part. It is easily seen that this surface has for expression,

$$2 \int_{0}^{a-y-\frac{b}{2}} N I_0 \cos\frac{\pi x}{a}\,dx - \int_{\frac{b}{2}-y}^{a-\frac{b}{2}-y} N I_0 \cos\frac{\pi x}{a}\,dx$$

which reduces to $\frac{2}{\pi}\sin\frac{b}{a}\frac{\pi}{2}\cos\frac{\pi y}{a} N I_0$.

To obtain the mean m.m.f. over the width of the polar step, it suffices to take, as previously stated, the mean of all the means when y varies from $-\frac{a}{2}$ to $+\frac{a}{2}$, whence

$$\mathfrak{F} = \frac{1}{b}\frac{2}{\pi}\sin\frac{b}{a}\frac{n}{2} N I_0 \int_{-\frac{a}{2}}^{+\frac{a}{2}} \cos\frac{\pi y}{a}\,dy,$$

which reduces to $\frac{4}{\pi^2}\sin\frac{b}{a}\frac{\pi}{2} N I_0$; and substituting the value $I\sqrt{2}$ for I_0 we have

$$\mathfrak{F} = \frac{4}{\pi^2}\sin\frac{b}{a}\frac{\pi}{2} N I \sqrt{2}.$$

When each coil of the armature comprises several concentric coils and separated from each other by two slots, it suffices, evidently, to apply the formula to each and take the sum of the results, in virtue of the principle that the integral of a sum is equal to the sum of the integrals of the parts. This will be done in the next part of this article.

The Gas Engine for Central Station Service.

At the February meeting of the New York Electrical Society Mr. Ralph D. Mershon read a paper with the above title, giving the results of a recent study of the engineering aspects of the gas engine question, in the course of which Mr. Mershon visited most of the large gas engine installations and manufactories both in this country and abroad. The paper sketches the theory of the gas engine, points out the important bearing of compression as affecting the initial temperature, and describes in detail the four-cycle and two-cycle types of engines.

Taking up the subject of governing, it is stated that only two methods have been used to any great extent practically. One of these is the method used with the original Otto engine and still much employed, especially with engines of the older type. This method consists in causing the engine to miss one or more working strokes. That is, instead of there being a working stroke in every four there would at light loads be a working stroke in every eight or every twelve, depending upon the load which the engine was carrying. This method of governing has the disadvantage of requiring a heavy fly-wheel, and that even with a heavy fly-wheel there will be considerable variation in speed. It has the advantage, however, of high efficiency at all loads, since whether the load be heavy or light the quality of the mixture and the compression previous to ignition are the same. The irregularity of the speed, however, consequent on this method of operation is such as to render it unsuitable for many kinds of work, especially for the driving of alternators in parallel.

The method usually employed, therefore, in governing gas engines, especially those of large sizes, and for electrical work, is that of varying the amount of mixture admitted to the cylinder at the same time endeavoring to keep its quality constant. With heavy loads when the engine is taking a cylinder full or practically full of explosive mixtures, the mixture can be suited for the compression which takes place, but with lighter loads it is evident that since the cylinder must be full the only way to preserve the quality of the mixture the same or approximately the same will be to endeavor to stratify the contents of the cylinder. That is, to first admit air to the cylinder and then a layer of the mixture, endeavoring to admit the mixture in such a way that it will not mix with the air, or at any rate to only a small extent, and so that at the back end of the cylinder, at least, there shall be a mixture sufficiently rich to properly ignite under the compression which has taken place. Whether or not this stratification actually does take place has been the subject of considerable dispute, but whether this theory be wholly or only partially correct or not correct at all, the fact remains that engines are operated successfully in the manner described. In one engine, at least, that of M. Letombe, the endeavor has been made to secure reliability in the matter of ignition independently of any question of stratification by making the compression higher at light loads, thus not only making the ignition more certain, but also increasing the efficiency of the engine at light loads over what it would be without the increase of compression.

After developing the principles of gas generators, the paper describes a particular form, represented in Fig. 1. At the left is shown the generator filled with the fuel from which the gas is to be obtained. This fuel burns at the bottom of the generator by reason of the air admitted to it at that point through the grate bars shown. The air, however, is not admitted by itself but is forced in along with and by means of a steam jet entering the fire box below the grate bars by way of the pipe shown, the steam being supplied by the boiler *B*. The mixture of air and steam coming in contact with the hot fuel at the grate bars, the air burns a portion of the fuel, thus forming carbonic oxide gas and supplying heat to split up the steam into its elements, the oxygen of the steam combining with a certain proportion of the incandescent carbon to form carbonous oxide. As this combination of carbonic oxide, carbonous oxide and hydrogen passes up through the hot bed of carbon, the carbonic oxide takes up an additional atom of carbon, forming carbonous oxide. There passes over the generator, therefore, by way of the pipe *B*, a mixture of hydrogen, carbonous oxide and the nitrogen contained in the air required for the process along with a small proportion of carbonic oxide. The generator is fed as shown by a properly sealed opening at the top, so that it may be charged without interfering with its operation.

After leaving the gas generator the hot gases pass out through the pipe *B*, heating in their course the water in the boiler as previously

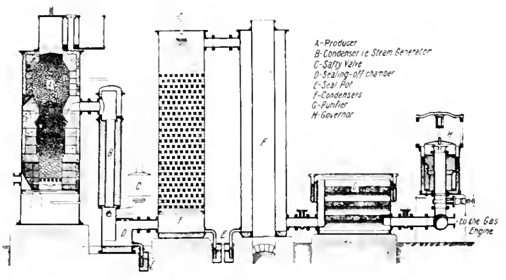


FIG. 1.—GAS GENERATOR.

mentioned and forming the steam for use in the generator. The gases then pass into the scrubber and the cooling chamber, *F*, *F*, in which the gas is cooled and cleaned by a spray of water sent through a checker work or through loosely piled coke. It then passes through the purifier, *G*, which removes such dust as there may remain in it and takes out the superfluous moisture. *H* is a small gas tank or equalizer for reducing the pulsation in the main occurring at the time when the engine is drawing a supply of gas.

There are many other forms of gas generators, but most of them operate on a principle simliar to that above described. This particular generator gives satisfactory results only with anthracite coal or coke. The generators for using bituminous coal require a somewhat different method of construction and operation from that described, because of the fact that with bituminous coal there are given off a number of tar products which must be either all converted into gas or completely washed from the gas before it is used in the engine. If the gas contains any considerable amount of these tar products, there will be a great deal of trouble in the operation of the engine due to the gumming up of the cylinders and valves. The problem of a gas generator for bituminous coal has not in the past received as much attention as that for anthracite coal or coke, and is not now so generally in use. There are, however, a number of bituminous coal gas generators on the market at this time, although most of them depend for their success upon a complete washing of all tar products from the gas before it is used. There are some generators, however, which may be now considered as having passed the experimental stage in which all or practically all of the products of the coal are converted into gas and the amount of washing or scrubbing required is, therefore, comparatively small. It seems pretty certain that a number of these generators of different makes will shortly be upon the market. Mr. Mershon stated that while in Germany he saw two generators of this kind in operation, one of which, both as to the principle used and as to the results which had been so far obtained, seemed to give every evidence of fulfilling the requirements. In a number of the bituminous generators in which the products of distillation are not all converted into gas there are obtained in the course of purification by-products of sufficient value to enable in some cases a return of about one dollar per ton of coal used over and above the expenses of operating the plant; such a showing as this cannot, however, be made except in plants of considerable size, and in small plants the installation of a by-product plant is not worth considering. The thermal efficiency of these gas generating plants is generally about 80 per cent.; that is, the gas produced by them contains about 80 per cent. of the total calorific power of the coal used.

Mr. Mershon stated that the cost of the gas engine is considerably in excess of that of the steam engine, and as compared with the steam turbine the discrepancy is even greater. There is a point of difference between the steam prime-movers and the gas engine which further exaggerates any relative cost which may be given per horse-power. The steam turbine and steam engine have a certain amount of overload capacity. That is to say, they are capable of operating, though at somewhat impaired efficiency, at loads considerably in excess of their rated output or the output at which they give the best performance. The gas engine, however, has, properly, no overload capacity. Its performance improves up to the point where it cannot carry any further load and at which any further loading causes it to slow down. This is not strictly true for engines of the two-stroke type, which have a slight overload capacity beyond the point of best performance, but this overload capacity does not exceed 20 per cent. of the rating capacity and is probably less. With the four-stroke engine, however, the statement as regards overloads holds.

It is necessary, then, in purchasing gas engines to provide for a rated capacity approximately equal to the overload which will have to be carried at any time, so that a comparison of prices on the basis of the cost per horse-power does not always give a correct idea of the relative costs, because in the case of the gas engine we must provide for a greater total number of rated horse-power. The quoted prices on the gas engines in this country at the present time vary quite surprisingly. Depending on the maker quoting, the prices on a horse-power basis range from 60 per cent. greater than for a steam engine to over twice the steam engine figures. In comparing the gas engine with the steam turbine prices we find a still greater discrepancy. In order to make the comparison it is necessary to add to the cost of the gas engine, the price of a suitable alternator, since the steam turbines are always furnished with the alternator which they drive. If this is done it will result in a cost per kilowatt of output at least twice as great in the case of the gas engine as in the case of the steam turbine, and if the comparison be made on the basis of a suitable overload capacity, the discrepancy will be even greater.

The cost of the gas generating plant for use in connection with

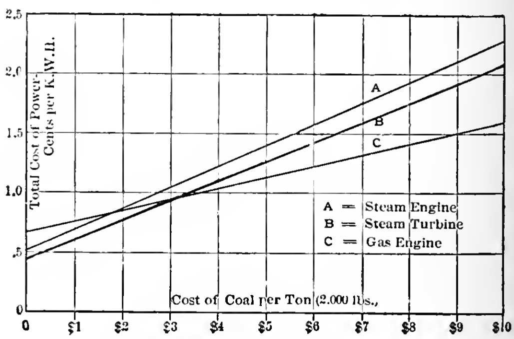

FIG. 2.—COMPARATIVE CURVES.

the gas engine may be taken as being about twice the cost of the steam boilers necessary for use in connection with a steam prime-motor. This is for a simple gas generator and cleaning plant, without any installation for the production of by-products.

It will be seen, therefore, that the cost of a gas engine plant, including the necessary gas generator, is considerably in excess of the cost of a steam plant for the same service, especially if the steam prime-movers be turbines. The cost of maintenance and the figure which must be taken for depreciation on such plant is, therefore, correspondingly higher, and the cost of the attendance also greater, since it requires a somewhat better class of men to handle a gas plant. On the other hand, the efficiency of the gas plant is very much better than that of the steam plant, the gas plant requiring for the same service about half the coal required by the steam engine plant and a little more than half that required by the steam turbine plant.

In order to give an idea as to the relative costs of electric power by the three types of plant, and the influence that the cost of fuel has upon the cost of power, figures were presented for a steam engine plant, a steam turbine plant and a gas engine plant, for the same service. In these figures everything is included properly chargeable against the cost of power.

It is assuming in each case that current is to be supplied to a load having a load factor of .5, and that the peak load is 1,500 kw. It is assumed that this load will be carried by four generators having a rated capacity of 400 kw each, and operating when necessary at 25 per cent. overload. The generators are to be cut in and out of service in such a way that the average efficiency of each unit will be the same as though it ran continuously at 75 per cent. of its rated capacity. The thermal value of the coal is taken as 12,500 B.T.U. per pound, and it is assumed that this coal will evaporate seven pounds of steam when burned under the boilers, and when used in the gas generators will produce gas having a total thermal value of 10,000 B.T.U. It is assumed that a steam pressure of 150 pounds is to be used and that the steam is to be superheated to 150° F. above its normal temperature. Under these conditions the following figures for performance are taken, being such as will be guaranteed by the makers of the various pieces of apparatus: Steam engine, 12 pounds per brake hp-hour; steam turbine, 18 pounds per kw-hour; gas engine, 10,000 B.T.U. per brake hp-hour.

Suitable modifications of these values were made to take care of the fact that the units are to run at 75 per cent. of their rating capacity, and to take care of condensation and auxiliaries in the case of the steam plants. Making use of these figures in connection with the costs necessary for such estimates, there were obtained the results embodied in the curves in Fig. 2. It is to be understood that these curves include everything properly chargeable against the cost of power, including interest, depreciation and renewals on the whole installation and supplies, labor and fuel. The line *A* shows the cost for a steam engine plant, *B* for a steam turbine plant, and *C* for a gas engine plant. The slope of these lines shows in each case the increase in power cost as the cost of the fuel increases. The point at which the line *C* crosses the other two lines shows the cost of fuel at which the gas engine plant is on a parity with the steam engine plant and the steam turbine, respectively, as regards the total cost of power. These curves give us an idea, therefore, of the cost of fuel at which it would begin to pay, under the present prices for apparatus, to install a gas engine plant rather than a steam plant. As will be seen from the curves, the gas engine plant and the steam engine are at a parity with coal costing about $1.85, while the point of equality with respect to the steam turbine plant is with coal at about $3.

It is believed that these curves show the relative performance of such plants under the condition assumed pretty fairly no matter what modifications might be made in the estimates, since while the modifications might change to some extent, the actual value for the cost of power, the relative value will not be much changed by a modification common to all of the plants. It should be borne in mind also that these figures are made on the assumption of a load having a load factor of .5, and that for more continuous service the gas engine will make a much better showing. It should also be borne in mind that these estimates are made without reference to any recovery of by-products, and that such recovery would very materially alter the showing made.

An inspection of these curves at the point where the value of the fuel is zero shows very plainly that, if, as it has sometimes been proposed to do, plants be installed at coal mines for the generation of power, a steam turbine and not a gas engine plant should be used unless a plant for the recovery of by-products be made a part of the installation.

The relative values here arrived at will no doubt have to be changed with the progress in the gas engine art. The gas engine equipment will become cheaper as its use becomes more general, and Mr. Mershon considers that this, in connection with the fact that some hard work is being done in the endeavor to produce a gas turbine, permits one to look forward to a time not far off when gas prime-movers of some sort will be installed instead of steam prime-movers.

Western Union and Wireless Telegraphy.

The Western Union Telegraph Company is now collecting and distributing messages for the marine service of the Marconi Wireless Telegraph Company of America. Postal Telegraph and Marconi have for some time past been working under a similar arrangement. The Marconi message for transmission to ocean steamers may now be accepted at any telegraph office in the United States or Canada.

Calculation of Motor Starting Rheostats.

By F. MEURER AND A. SIMON.

IN the ELECTRICAL WORLD AND ENGINEER of January 9 Mr. A. H. Ford gives a method for the calculation of motor-starting rheostats, which appears to be the same method suggested in *Elektrotechnische Zeitschrift,* 1894, page 644, by Prof. Görges, for shunt motors. At the same time Mr. Görges gave a diagram for the various steps of the rheostat. This method seems to be little known in America, but has been familiar to engineers of Germany for years, where it is held in favor on account of its simplicity. The method is as follows, using the same notation as Mr. Ford:

It will be seen from equation (a) that the steps

$$R_m = a R_a \ (1 + a)^{m-1}$$

follow a geometrical progression. The sum of the first m steps is:

$$R_1 + R_2 + R_3 + \ldots R_m = a \ R_a \ \frac{(1+a)^m - 1}{(1+a) - 1}$$

$$= R_a \ [(1+a)^m - 1].$$

Including the resistance of armature and connections, we have:

$$R_a + R_1 + R_2 + \ldots R_m = R_a \ (1 + a)^m.$$

This equation follows also a geometrical progression, when m has in

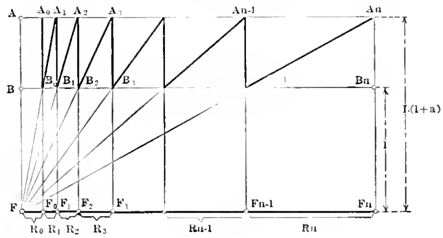

FIG. 1.

turn values 1, 2, 3 . . . m . . . . n, and will give a geometrical construction of the steps of the resistance. Referring to Fig. 1,

$$F F_0 = R_a$$

and $\triangle \ F B_0 F_0 \propto F A_1 F_1$:

therefore,

$$\frac{F F_1}{F F_0} = \frac{F_1 A_1}{F_0 B_0} = \frac{I \ (1 + a)}{I} = 1 + a.$$

Further, $F F_1 = R_a \ (1 + a) = R_a + R_1,$

and

$$\frac{F F_2}{F F_1} = \frac{F_2 A_2}{F_1 B_1} = \frac{I \ (1 + a)}{I} = 1 + a,$$

or $F F_2 = F F_1 \ (1 + a) = R_a \ (1 + a)^2 = R_a + R_1 + R_2$, etc. Knowing R_a and assuming the minimum (I) and normal current (I_0) and $a > o$, the number of steps, n, is found from formula (b). In the above diagram the value of the various steps are, therefore, found sufficiently correct, without any calculation.

The same diagram also shows the speed of the armature at the time when the various steps are short-circuited, in the points B_{n-1} . . . . . . B_3, B_2, B_1, B_0, corresponding to the currents I and the time during which the lever has to touch the contact of this step, before the latter is cut out. At the moment, when the *mth* step is cut out,

$$E_{am} = E - I \ (R_a + R_1 + \ldots . + R_m)$$

$$= I R_a \ [(1 + a)^n - (1 + a)^m]$$

E_{am} the counter e.m.f. is proportional to the speed v; therefore, v_m *prop* $(1 + a)^n - (1 + a)^m$.

Transferring the above developed relations to the diagram, the geometrical measuring is easily understood. Fig. 2 is the diagram of the speeds. The end of the starting period is of especial interest. In point B_0 the last step is short-circuited, the current rises for the last time to the value $I \ (1 + a)$ to point A_0, and then it decreases according to the rule,

$$I_t = I_0 + [I\ (1 + a) - I_0]\ e^{-\frac{t}{T}},$$

accelerating the armature according to

$$v_t = v - (v - v_n)\ e^{-\frac{t}{T}},$$

where v is the constant speed for I_0; v_t and I_t the speed and current t seconds after the short-circuiting of the starter; T a constant depending on the moment of inertia of the rotating masses, the angular velocity and the resistance, R_a.

Owing to the asymptotic character of these equations, the constant and normal current and speed are reached after an infinite time; in

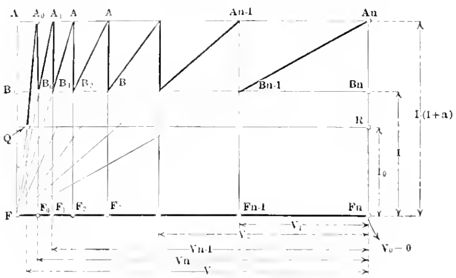

FIG. 2.

practice, however, this condition is reached in a short time. In Fig. 2 the constant speed for the current I_0 and the voltage E is $Q\ R$.

In the time that elapses between the touching of two successive steps there is an average excessive current above the normal current I_0 which is between the values $I\ (1 + a) - I_0$ and $I - I_0$. This current, which is of the same amount for all steps, accelerates the armature with an average acceleration as follows:

$$v_m - v_{m-1} = p.t,$$

$$v_m - v_{m-1}\ prop.\ [(1 + a)^n - (1 + a)^{m-1} - (1 + a)^n + (1 + a)^m],$$

$$v_m - v_{m-1}\ prop.\ (1 + a)^m - (1 + a)^{m-1},$$
$$prop.\ a\ (1 + a)^{m-1}.$$

According to equation (a),

$$R_m = a\ R_a\ (1 + a)^{m-1};$$

therefore, t is proportional to R_m. It is found that the time, during which the lever has to touch each contact before touching the following one, is proportional to the resistance of the respective step. This relation is important for the dimensioning of the capacity of the resistance of each step, when the starter is to be designed for intermittent duty.

The three diagrams may be united in a single one, which contains all the points of interest in calculating a motor starter, the resistances of the various steps, the speeds and the starting times.

A simple way of finding the different steps with the slide rule is given by E. Pochin (*Elektrotechnische Zeitschrift* 97, p. 346). After

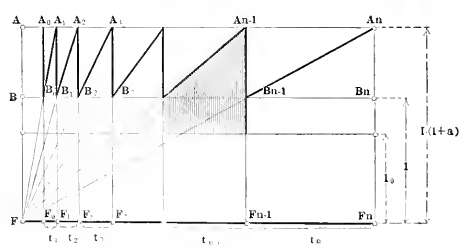

FIG. 3.

Mr. Görges, F. Erens (*Elektrotechnische Zeitschrift* 99), Neidt (*Elektrotechnische Zeitschrift* 99, No. 2), and Bragstadt gave simple diagrams for series motors, and Max Müller (*Elektrotechnische Zeitschrift* 02, p. 513), for dynamic brake rheostats for series motors. Similar diagrams have been developed for field rheostats for shunt dynamos and motors by Mr. Krause and others. On account of limited space, we cannot attempt to detail all of these methods, but would refer to the excellent book, "Die Gleichstrommaschine," by E. Arnold, Vol. II, where they are lucidly described.

The Design of Motor Starting Rheostats.

BY MAX FREIMARK.

The article of Mr. Arthur H. Ford in your issue of January 9 leads me to submit a similar and well-known method for designing motor-starting rheostats.

Assuming that the object is to make the starting current, always equal to the normal current i, $i_s = i$. If, in this case, R is the entire resistance of the armature, connections and starter, E the line e.m.f. (see Fig. 1), then we have the equation:

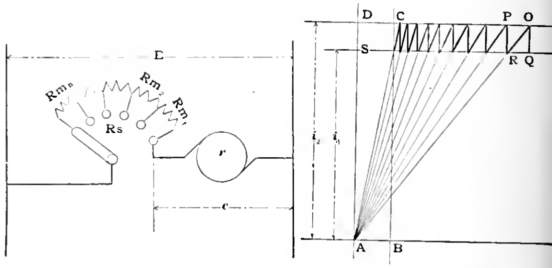
$$R = \frac{E}{i} = \frac{E}{i_s}.$$

If e is the motor e.m.f., r = the resistance of the motor, then $E - e$ $= i\,R$, or $i_1 = \dfrac{E - e}{R_s + r}$, R_s being the starter resistance,

$$i_2 = \frac{E - e}{R_s + r - R_{m_n}},$$

when one section (R_{m_n}) is cut out.

As stated by Mr. Ford, there will be a continual increase and



FIGS. 1 AND 2.

decrease of the current between i_1 and i_2, as is to be seen from Fig. 2.

The ratio of these extreme currents may be λ

$$\lambda = \frac{i_2}{i_1}, \text{ or } \lambda = \frac{R_s + r}{R_s + r - R_{m_n}} = \frac{R}{R - R_{m_n}} = \frac{R}{R_{n-1}},$$

n being the number of sections.

$r_1 = r + R_{m_1};$

$r_2 = r + R_{m_1} + R_{m_2};\ \ldots\ldots$

$r_n = r + R_{m_1} + R_{m_2} + \ldots + R_{m\,(n-1)} + R_{m_n} = R$

$$\frac{r_n}{r_{n-1}} = \frac{r_1}{r} = \frac{r_2}{r_1}, \text{ etc.}$$

$r_1 = \lambda\ .\ r;$

$r_2 = \lambda\ r_1 = r\ .\ \lambda^2$ as $r_1 = \lambda\ .\ r;\ \ldots\ldots$

$r_n = \lambda\ .\ r_{n-1} = r\ .\ \lambda^n$

That is to say, the resistance must increase geometrically with λ.

$$\frac{r}{R} = a$$

When $i_s = i$ then $a = \varepsilon =$ per cent. e.m.f. loss, since

$$E = i_s\ R,$$

$$\varepsilon\ .\ E = i\ .\ r,$$

$$= \frac{i}{i_s} \cdot \frac{r}{R} = a$$

As now $n = \dfrac{-\log a}{\log \lambda}$, the number n of sections is fixed by the allowed drop of pressure in the armature.

The following table gives some usual values of a and n, and shows the influence of λ the ratio of i_2 and i_1:

a = 0.03	0.04	0.05	
λ			n
2.02	1.91	1.82	5
1.42	1.58	1.35	10
1.26	1.24	1.22	15
1.19	1 17	1.16	20
1.12	1.11	1.10	30
1.09	1.08	1.08	40
1.06	1.055	1.05	60

The conditions are shown graphically in Fig. 2, where

$$AB = CD = r,$$

$$QS = r_n\ ;\ RS = r_{n-1},\ \text{etc},$$

$$\frac{OD}{RS} = \frac{AD}{AS} = \frac{i_2}{i_1},$$

$$\frac{OD}{RS} = \frac{r_n}{r_{n-1}},$$

$$\frac{OD}{PD} = \frac{r_n}{r_{n-1}} = \lambda$$

The Choice of Wattmeters.

BY H. P. DAVIS.

I HAVE read with interest the views regarding the choice of wattmeters expressed by Messrs. MacGahan and Howe in recent issues of your journal. The important part played in electrical economy by the service meter makes this subject one worthy of careful consideration, and as it is possible that a comparison of the statements made by these gentlemen may be of some value, I beg to submit the following conclusions reached by a study of the subject as thus presented.

It is well to note that Mr. MacGahan and Mr. Howe agree in fundamentals, but differ in the application of theory to practice. They unite in saying that the prime requisite in a wattmeter is accuracy over a long period of time. They, however, take issue in regard to the way in which long-lived accuracy is to be attained, and the relative value placed upon various functions and features common to such instruments, and it seems to me that their differences are mainly those caused by the difference in their point of view. Mr. MacGahan favors a meter for which he claims accuracy within 2 per cent.; Mr. Howe insists that he does not find that such a claim is borne out by the meter with which he is familiar. Mr. MacGahan espouses a sealed meter in which the factory calibration is preserved intact; Mr. Howe thinks it preferable to furnish meters unsealed, that customers may have the ready access to the adjustments which he finds necessary. Mr. MacGahan asserts that the friction of the counting train is negligible; but Mr. Howe's observations lead him to believe to the contrary. Mr. MacGahan prefers a high ratio of torque to friction in conjunction with a light, movable element and reduced friction; Mr. Howe thinks the desired long-lived efficiency can best be secured by increasing the torque through the use of a heavier movable element with the increased jewel wear. Each of these gentlemen doubtless states the facts as he finds them in his personal experience, and a ready assent can be given to their assertions in the main, so far as they are the results of personal investigation in a limited field. It is only when a general application is made that their claims require especial comment.

Mr. MacGahan says that all the variations of actual service should not produce a maximum error in registration of over 2 per cent. of the rated capacity. This Mr. Howe denies, claiming that a variation in standards will ordinarily be 1 per cent., while a 10 per cent. variation in frequency or voltage will cause an error of an equal amount, making it possible for other influences to combine to produce an error in excess of the 2 per cent. Mr. Howe may find such conditions prevailing in his field, but meter experts who are accustomed to the handling and testing of the sealed type of meters of high sensibility and with light, movable elements, can testify that the maximum aberration for a 10 per cent. variation in frequency and voltage rarely exceed ½ per cent., leaving practically 1½ per cent. of margin for variations in standards, errors in observations, etc.

Mr. MacGahan's contention that a sealed meter possesses material advantages over one not sealed, and Mr. Howe's arguments in favor of an open instrument simply carry along an old discussion which must, after all, be decided by the individual companies using wattmeters, and by their meter experts. Mr. Howe assumes that a sealed meter is a delicate and intricate one, which the manufacturers dare not leave open, and that the presence of the seal discourages the owner from making his own repairs. Would it not be more logical to assume that a meter which can be finally adjusted at the factory for use upon a circuit, can be shipped to destination, carried to the point of installation in the lineman's wagon and put into service with no attention from the meter expert, possesses an unusual degree of strength and stability? Instead of the absence of a seal being a virtue and a feature to be desired, is not the ordinary meter expert liable to think it a weakness, particularly when he reflects that the meter was left unsealed because he must make a final adjustment of the movable element after the meter is installed, its construction being such that it cannot be shipped ready for service?

All manufacturers of wattmeters, whether sealed or open, guarantee the materials and workmanship of their instruments. If the purchaser of a sealed meter does not care for the advantages thus gained, he can easily break the seals, and obtain exactly the same conditions as those given by an unsealed meter. He will have an instrument, the workmanship and material of which are guaranteed, but without any means of knowing whether the adjustments have been tampered with, and, therefore, no guaranty of the calibration.

The benefits derived from preserving the factory calibration made by trained experts are constantly winning new recognition, as instances multiply where this calibration has proven of value. In one installation, after 1,400 wattmeters had been used for over two years under the factory seal, only 18 of them required any attention, and these were easily restored to their original accuracy by the local meter expert, who did not find the seal any impediment to his making new adjustments or repairs. The ordinary meter man, who desires to give his employers the best of results, would naturally be expected to prefer a guaranteed calibration of known accuracy to the dubious privilege of freely changing adjustments when such changes are made an inevitable part of the operation of installation.

Mr. MacGahan claims that the friction of the counting train is negligible, but Mr. Howe affirms that such is not the case. Apparently the difference is again one of construction. Mr. MacGahan's statement is evidently based upon the use of a pinion upon the shaft of the moving element, which engages the counting train, the inevitable worm being placed where the speed is lower and the leverage of the gears increased; while Mr. Howe's counter statement is as evidently based upon the fact that he has in consideration a meter with a worm upon the shaft, with greatly increased friction. Any meter expert who has at his command meters with the different forms of construction can easily demonstrate that while with the pinion and gear he cannot detect any difference in operation whether the counting train is connected or removed, there is a very appreciable decrease in friction when the counting train is removed from a meter which employs a worm on the shaft.

Mr. MacGahan declares for a high ratio of torque to friction, and Mr. Howe for a high torque with heavier movable element and consequent increase in friction. Now, both state that the prime requisite is length of accurate service. If it be true—as experience has amply shown—that wattmeters first develop weakness through wear in the jeweled bearing, does it not logically follow that any increase in friction which shortens the life of this bearing reduces the length of accurate service? A powerful drag or pull upon the rotating medium is of value in overcoming friction, particularly upon light loads, when the ratio of friction to torque is highest, since friction is a fixed quantity, while torque varies with the load; but any increase in torque gained at the expense of the life of the jewel is an injury rather than a benefit. The wise designer will first reduce the friction to the lowest possible point by using the best bearings he can devise and by lightening the weight of the movable element as much as he can and still have ample torque for accurate registry upon light loads for any length of time under normal conditions of jewel wear.

Hiccoughs Cured by Electricity.

Frank Green, of Trenton, N. J., was recently attacked with severe hiccoughing. After three days of suffering an electric current was, according to a dispatch from that city, applied to his body. At first light currents were used and afterwards increased in strength. Improvement was noted from the first application, and finally, with a sudden shock, the paroxysms ceased.

Telephone Transmitters.—VII.

By Arthur V. Abbott, C.E.

Testing Transmitters and Receivers.—To determine the merit of transmitters or receivers is one of the most difficult of tests. This is chiefly because there is no recognized standard or unit of measure. People vary enormously both in their ability to talk and to understand, over a telephone line entirely apart from the ability of the apparatus to transmit and reproduce sound. Hence, what to one person seems sufficient will be perhaps more than adequate to another, and unsatisfactory to a third. It is common to test transmitters and receivers by arranging a circuit between two rooms out of earshot of each other, in one of which the transmitters are placed and in the other the receivers. An inspector at the transmitter end counts from one to ten in a rather loud, sustained tone into one instrument after the other, while another inspector at the receiving end forms the best conclusion he may as to the relative efficiency of the various instruments. While trained observers develop an astonishing skill in detecting differences in transmission, such a method compared with the more exact measurements of other branches of electrical engineering appears crude in the extreme.

To the practical man quality of transmission is proportional to the ability to understand each word individually without requiring his correspondent to repeat it, and that combination of transmitter and receiver is the best which, over lines of varying lengths, requires on the whole the least repetition. For testing purposes, therefore, it is necessary to provide a transmitter and receiver with which with all other instruments may be compared, and a variable line over which tests can be made. As there is no established standard instrument, it matters little what ones are selected for this purpose, for all results will be relative only. In a general way two of the best instruments obtainable should be taken, set aside for the purpose and used for nothing else. For the line nothing can excel an actual working line, but as tests should include trials over at least a thousand miles of wire, there are few who can avail themselves of such a plant, and it is equally difficult to carry on experiments on a commercial circuit. It is, therefore, better to build an artificial line exclusively for test purposes. For this purpose a number of coils of wire can be made each of which shall represent, by having the same resistance, inductance and capacity, a certain section, say ten or one hundred miles of line.

The artificial line is best made by preparing 220 spools of wood. Each spool should have a 1-in. hole through its center and be about 3½ in. over all in diameter and 3½ in. high. The flanges and core should be about ¼ in. thick, leaving a winding space about 3 in. x 3 in. The spools should be made of soft wood thoroughly baked and boiled in paraffine. To represent aerial lines No. 20 wire is a convenient size to use, while for cable lines No. 28 or No. 30. Each spool should be wound with sufficient wire to represent 10 miles of open wire or 1 mile of cable. To secure the proper inductance more or less of the wire can be wound non-inductively, so that each spool when finished shall have accurately the resistance and inductance of either 10 miles of open wire or 1 mile of cable. The necessary capacity is best secured by making a small condenser of tin-foil and paraffined paper, exactly like a sub-station condenser. For each pair of wire spools the condenser should have a capacity of .1 mf. and for each cable wire spool .08 mf. When completed a frame is to be prepared having two long rubber or glass rods. On each rod 110 coils, 10 representing 10 miles of cable wire, and 100 each representing 10 miles of open wire, are placed. Between the two rods a substantial wooden strip is arranged underneath which the condensers are secured, and on top of which there are a number of brass plugs similar to those used in Wheatstone bridges. A condenser is joined between each pair of coils, and all coils are connected in series through the plugs, so that each plug when in its place short-circuits a pair of coils. Thus any combination of cable and open wire up to 1,010 miles can be obtained. Such an apparatus can be built for about $500, and while seemingly elaborate and expensive is essential for the proper testing of telephone apparatus.

For actual trials there should be three inspectors—a speaker, a listener and a manipulator—for in order to avoid the unconscious error due to personal equation, neither the speaker nor the listener should know anything about the apparatus they are testing, which should be arranged in all cases entirely independently of their knowledge. The three rooms are necessarily entirely distinct from each other, both visibly and audibly. The transmitters should be placed in room No. 1, the artificial line in No. 2 (the middle one), and the receivers in No. 3. In the following method of testing the listener must be an expert stenographer, and the method consists in finding the percentage of errors between sentences uttered in the transmitter and those received with varying line length. The first thing is to determine the *error coefficient* of the speaker and listener. The speaker reads to the listener in the usual conversational tone, and at a fair rate of speed, 10 sections of 1,000 words each, of 10 different subjects. The listener then transcribes the 10 selections, and the manipulator compares the transcription with the original and counts the number of errors made. This is the *error coefficient* and is usually from 3 per cent. to 5 per cent. The manipulator then, unknown to both speaker and listener, adjusts either a transmitter or a receiver to be tested, for only one instrument can be tried at once. The speaker then reads to the listener over the telephone line 10 different selections of 1,000 words each. After each set of 1,000 words the manipulator changes the length of the line. The listener then transcribes the shorthand notes, the manipulator compares with the original and counts errors. The results may then be plotted as a function of line length, and by making a number of such tests with different transmitters and receivers quite accurate relative results can be secured.

The curves of Fig. 54 are illustrative of the method. The horizontal scale is the length of the artificial line in miles, while the left-hand scale is percentage of error. The line marked "error line" is the percentage of normal errors, when the speaker read directly to the stenographer. Curves *A*, *B* and *C* show the results of tests on three rather well-known types of transmitters working with the same receiver. Transmitter *A* showed the least percentage of error. Instrument *B* showed about 2 per cent. more error on short lines and 30 per cent. more on long lines, indicating a deficiency in volume. Instrument *C* was poorer than *B* on lines up to 200 miles, and subsequently gave marked falling off in volume.

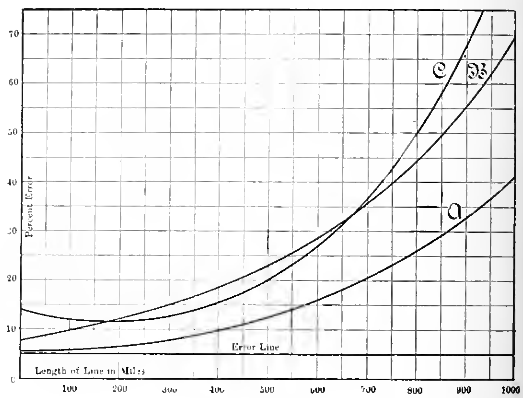


FIG. 54.—CURVES OF TESTS.

Tests as thus described show what may be termed the *general efficiency* of transmission. It is also well to compare volume by actuating the transmitter by an organ pipe, blown by a blast of constant pressure, and measuring the distance from the ear of an observer at which the sound first becomes audible. The listener should be blindfolded and the manipulator should noiselessly move the receiver to and from the ear of the listener along a graduated scale, noting both the distance at which the sound is first perceived, when the instrument *approaches* the ear, and the point at which sound *fails* to be heard when it recedes. The mean of a number of such tests gives relative volume. To test for articulation the speaker should read to the listener a list of a thousand words of great similarity, such as fine, rhyme, dine, sign, mine, etc.; mowing, rowing, throwing, going, etc. Also the letters of the alphabet in heterogeneous order. These tests should be conducted on different lengths of line and the percentages of errors calculated and plotted as previously described. Finally, a comparison of the general test, and tests for loudness and articulation showing the net result of all three, will give quite acurate ideas of relative excellence.

Methods of Signaling and Operating in Telephone Exchanges.—V.

By KEMPSTER B. MILLER AND CHARLES S. WINSTON.

WESTERN ELECTRIC TOLL SYSTEMS.

THE systems for handling toll business installed by the Western Electric Company are numerous, and differ as widely as the methods it has employed in handling most other branches of telephone service. However, during the period beginning at about the time when the common battery multiple switchboard came into general use and ending about two years ago, two methods stand out conspicuously from the others, as they have been used in many large installations with generally better results. While these two systems were similar in operation and in the results accomplished, they differ materially in many respects.

In each of these systems the connecting links between the toll board and the common battery board are made by means of toll trunk circuits. These circuits end in plugs and lamps at one or more toll-switching positions on the local multiple board, and appear at the toll board in lamps and keys at a recording operator's position, and in jacks multipled through the toll line sections.

These two systems, which will be designated for convenience as "A" and "B," differ mainly in that one of them, system "A," only two wires are used in each trunk circuit extending between the toll board and the local multiple board, while in the other, system "B," three wires are required for the same purpose. Of course, where the toll and local boards are located in the same building, the cost of installing and maintaining three wires for each toll trunk circuit instead of two is of comparatively little moment, and is to be tolerated, if, by doing so, any material reduction in the complexity of the apparatus or gain in the method of operation is to be effected. Where, however, the toll board is located at a considerable distance from the local board or boards, as is usually the case in large cities, the use of three wires for each toll trunk circuit becomes a serious matter, and is generally avoided.

System "A" probably owes its existence to this difference more than to any other one thing.

In neither system are cord circuits provided at the recording operators' positions, as keys, in the toll trunk circuits, which are located in the face of the board, furnish means for doing all of the work required.

The clearing-out drop ordinarily used in the cord circuits in both systems is an electrically restoring drop of the well-known Western Electric type, which is restored whenever the operator throws the listening key which is connected with the corresponding cord circuit. Each of these drops is wired through an additional key so that it may be cut out of circuit in case of a very long-distance connection over which talking is difficult, in which the bridge afforded by the drop across the circuit might interfere with the transmission.

WESTERN ELECTRIC TOLL SYSTEM "A," USING TWO WIRES IN TOLL TRUNK CIRCUITS.

In this system, which is the one used until recently by the Bell Companies in cities where the toll board was at a considerable distance from the local board, a repeating coil is located in each toll trunk circuit, and on this account the toll switching operator at the local board rings the bells of common battery subscribers for whom long-distance calls are received. The cord circuits used by the toll operators in establishing connections between toll and common battery subscribers are the same as those used in making toll-to-toll connections. In order to inform the toll-switching operator at the local board when the subscriber whom she has been ringing answers, a ringing lamp is provided in connection with each toll trunk plug at the toll switching position; and in order to give this operator a signal for taking down the connection, a disconnect lamp also is associated with each of the trunk plugs at her position.

The operation of this system is as follows, reference being made to Fig. 9. A common battery or local subscriber desiring to converse with a toll subscriber will signal his operator in the ordinary manner, and on the response of the operator will ask for "long distance." The operator will then speak over an order wire to a toll switching operator at the local board, and tell her that a certain subscriber desires a toll connection. The toll trunk operator will then insert a toll trunk plug which is not in use into the multiple jack of that line, and the subscriber's operator will remove the answering plug from the answering jack of the subscriber's line. The act on the part of the toll trunk operator of inserting the toll trunk plug into the multiple jack will, since the subscriber of that line has his receiver off the hook, light a lamp with a white cap, located in the face of the toll board at the recording operator's position. The lighting of this lamp corresponding to any toll trunk line is therefore dependent, first, on the toll trunk operator having made a connection between the end of that line and the line of a subscriber; second, on that subscriber having his receiver off the hook. The recording operator, in response to this signal, will throw the listening key associated with

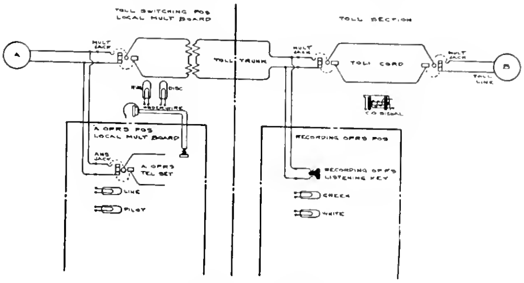

FIG. 9.—SHOWING CONNECTION OF LOCAL TO TOLL SUBSCRIBERS. WESTERN ELECTRIC "A."

this lamp and located directly below it. This act will extinguish the white lamp and light in its place a green one. It will also connect the operator's telephone circuit to the toll trunk line, and therefore enable her to communicate over it with the subscriber. She is thus enabled to make out a ticket containing the proper data for the toll connection, and will pass it on to one of the toll line operators. Having done this she will restore her listening key, but in doing so she will not extinguish the green lamp, as it remains lighted until the toll operator in taking up the connection inserts a plug into the multiple jack of the toll trunk line.

The purpose in furnishing two lamps at the recording operator's position is to make it impossible for the recording operator, after she has answered the call and before the toll operator has taken up the connection, to forget that she has already responded to the signal of the white lamp, and again speak to the subscriber. If one lamp only were furnished, it would be necessary to arrange it so that it would relight when the recording operator threw the listening key back to its normal position; in order to enable the subscriber to signal while waiting for the toll operator to respond.

The toll line operator having received a ticket from the recording operator, will insert the answering plug of a toll cord into a multiple jack of the toll trunk line. This, as before stated, will extinguish the green lamp at the recording operator's position. She will then insert the calling plug into the multiple jack of the desired line, and thus, after ringing, bring the two subscribers together for conversation.

At the end of the conversation the clearing out signal will be received at the toll board by the falling of the drop in the toll cord circuit. Having received the clearing-out signal, the toll operator will remove the calling and answering plugs from the toll line jack and the toll trunk jack, respectively. The act of withdrawing the answering plug from the trunk jack will light the disconnect lamp at the toll trunk position, and the toll trunk operator will remove the plug from the multiple jack. The act of taking down the connection at both the toll position and the toll switching position has no effect upon the signals at the recording operator's position, that operator having finished all duties in regard to the connection when she passed the ticket to the toll operator.

When a toll subscriber desires to converse with a multiple board subscriber, he will signal the toll line operator in the regular manner by throwing down the line drop at the toll board. Of course, this may be done by the toll operator at a distant exchange. The toll operator will then insert an answering plug into the toll line jack, and after throwing the listening key to find out the number of the common battery line with which the connection is to be established, she will speak over an order wire to the toll trunk operator telling her that a toll connection is to be established with a certain common battery line. The toll trunk operator will designate the trunk for use in establishing the connection, and with the plug of this trunk will test the jack of that line. In case the line is busy, she will insert the trunk plug into a busy back jack which will notify the toll operator by "tone" that the line is busy. In case the line is free, she will insert the trunk plug into the multiple jack. The ringing lamp associated with the trunk plug at the toll trunk position will light immediately, and the toll trunk operator will ring the subscriber. When the subscriber answers the call, this ringing lamp goes out and cannot be relighted without first withdrawing the trunk plug from the jack. This connection is shown in Fig. 10.

At the end of conversation the toll line operator receives the disconnect signal in the same manner as at the end of a local to toll connection, and upon withdrawing the toll trunk plug from the toll trunk jack, lights the disconnect signal at the toll switching position on the multiple board, in the same manner.

The recording operator has nothing to do with establishing a connection from a toll to a local subscriber. In this case the toll line operator does all of the work at the toll board and makes out the ticket without the help of any other operator. Thus, it will be seen, that unless the charge is to be "reversed" the recording operator

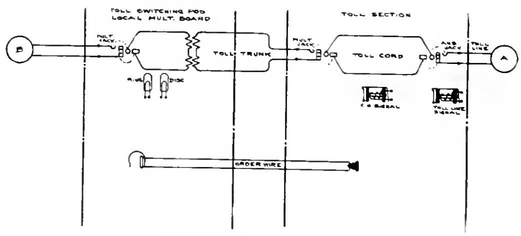

FIG. 10.—SHOWING CONNECTION OF TOLL TO LOCAL SUBSCRIBERS. WESTERN ELECTRIC "A."

always makes out the ticket when the charge is to be made against a common battery line, and the toll line operator when the toll station is to be charged for the connection. This is a guard against making mistakes and charging the wrong party for the conversation. If for any reason after a common battery subscriber has called for a toll connection and the switching operator has inserted a trunk plug into the multiple jack of the calling line and thus lighted the lamp at the recording operator's position, the recording operator does not desire to have the connection made, she will press a push button key associated with the toll trunk line in use, thus extinguishing the lamp at the recording operator's position and lighting the disconnect lamp at the toll switching operator's position.

WESTERN ELECTRIC TOLL SYSTEM B, USING THREE WIRES IN TOLL TRUNK CIRCUIT.

In this system the repeating coil, instead of being included in the trunk line circuit, as in system A, is included in the cord circuit at the toll board. One-half of each of these cord circuits is wired the same as half of a cord circuit at the local multiple board, the other half being wired, as in ordinary magneto practice, the clearing-out drop being bridged across the two strands of the cord. Each cord circuit is equipped with a key which is so wired that when thrown the repeating coil is cut out of the circuit and a straight circuit established between the two plugs so that the same pair of plugs can be used for establishing toll-to-toll connections, as is used for establishing toll to local connections, the only difference being in the position of the repeating coil key.

In this system a disconnect lamp but no ringing lamp appears in connection with the plug of each toll trunk circuit at the multiple switchboard end, but the toll trunk circuit contains no repeating coil, and therefore the toll line operators ring the bells of the local subscribers over these lines instead of having the toll trunk operator do this, as in system A. This is, of course, a better arrangement, and enables the toll operator to be the true master of the situation and to more properly supervise a call than where the toll trunk operator is compelled to do the ringing.

This system has not, to our knowledge, been used except in cases where the toll sections and multiple switchboard are located in the same building.

The operation of establishing a connection between a local and a toll subscriber is exactly the same in this as in Western Electric system A. The parts involved in such a connection are represented in Fig. 11, it being seen that the services of the subscriber's operator, the toll switching operator, the recording operator and the toll operator are all required.

At the end of the conversation a double clearing-out signal will be received at the toll board. The toll subscriber will, by turning his generator crank, throw the clearing-out drop, and, the local subscriber, by hanging up his receiver, will light the supervisory lamp associated with the local side of the toll cord circuit. The toll operator will then throw her listening key so as to restore the clearing-out drop, and listen in to satisfy herself that some one at the toll station does not desire another connection. She will then withdraw the plugs from the toll trunk and toll line jacks. The act of withdrawing the plug from the trunk jack will automatically light the disconnect signal at the switching operator's position on the local multiple board, and this operator will remove the trunk plug from the multiple jack of the local subscriber.

A push-button key is provided at the recording operator's position in connection with each toll trunk circuit, wired so that the recording operator can give the disconnect signal at the multiple switchboard, and extinguish the lamp associated with the trunk line at her own position in case she does not desire to have the connection established.

A toll to local connection is established in practically the same manner as in system A, the toll operator ordering up the connection at the toll switching position by order wire. As in that system, the A operator and the recording operator play no part in a toll to local connection. In this, however, the toll operator, instead of the toll switching operator, rings the local subscriber.

The method of making connections between toll subscribers in these two systems, A and B, is almost identical. In both cases a toll subscriber signals the toll board by turning the generator crank and thus throwing the line drop at the toll board. The operator will insert an answering plug, and after throwing her listening key, speak to the subscriber and find out that a connection is desired with some other toll station. In system A, the cord circuit can be used for making either a toll-to-toll or toll-to-local connection without change, but in system B the cord circuits are normally suited for making

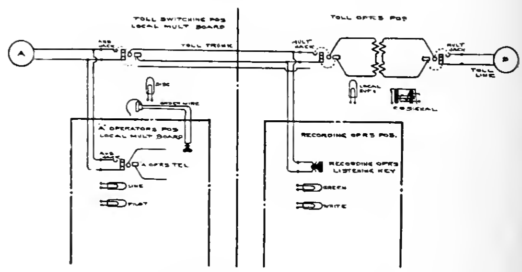

FIG. 11.—SHOWING CONNECTION OF LOCAL TO TOLL SUBSCRIBERS. WESTERN ELECTRIC "B."

connections between toll and local subscribers. On this account it is necessary for the toll operator in system B to throw a key associated with the cord circuit before this cord circuit can be used for connecting two toll subscribers. Having done this the remainder of the operation is the same as in system A. After testing, the operator will insert the calling plug, associated with the answering plug in use, into the multiple jack of the desired line, and ring. Until the subscriber answers, it is necessary for the operator to listen in at short intervals so as to know when the call is answered. The operator who has charge of the calling toll line will make out a ticket and record on it the duration of the conversation, the number of the calling and the number of the called toll stations and the names of the calling and called parties.

Each of these two systems has advantages over the other. A costs less than B, not only on account of having two wires in the trunk circuits instead of three, but because the number of repeating coils is less when located in the trunk circuits than when located in the toll cord circuits. In system A the method of operation at the toll line positions is less complicated, as the same pair of cords is adaptable without change to either toll-to-toll or toll-to-local connections, and the operator is, therefore, required to make no change in her cord circuits. In system B it is necessary after a circuit has been used for one class of service, for the operator to throw the repeating coil key before she can use the pair of cords for the other class of connections.

On the other hand, however, the second system enables the toll operator to properly supervise all toll connections, to ring up a common battery subscriber herself, and at the end of the conversation to receive a lamp disconnect signal directly from the common battery subscriber. This latter much facilitates the work of keeping track of the duration of conversation, as in this case there is no doubt in the mind of the toll operator, whose duty it is to measure the lapse of time, as to when the common battery subscriber is through talking.

New Telephone Patents.

METALLIC FRAME JACK STRIP.

Metallic frame jack strips are without doubt the present standard, and new types and variations of present ones are periodically appearing. The latest development in this line is a jack invented and patented by L. M. Ericsson, of Sweden. This jack is built up in rubber strips secured to a frame plate of sheet brass. The plate is slightly longer than the rubber strip and its projecting ends are designed to slide into slots in the jack stiles, so that the strip is thereby supported. The strip of jacks mounts from the front, being held against the stiles by cover plates, which hide the ends of the jack strips. The cover plates are in lengths equal to the width of five strips, and are secured by screws passing into the jack stiles.

DESK TELEPHONE STAND.

Another invention of Mr. Ericsson is a design for a desk telephone stand of a kind little used in this country. This stand is adapted for use with the hand microphone; that is, a transmitter and receiver mounted upon a handle so that when the former confronts the mouth the latter will be against the ear. Mr. Ericsson's stand is a four-legged metal frame from the top of which a sliding rod projects. The bottom of this contacts with springs which serve the purpose of the ordinary hook switch, while the top carries a cross bar with prongs adapted to receive the hand microphone. The action is almost obvious, the weight of the microphone of course throwing the circuit changer.

CASING FOR TELEPHONES.

In this connection it may be well to consider a patent covering a "Casing for Telephones," as this is designed for instruments of the hand microphone type. Fig. 1 shows a side view of the instrument

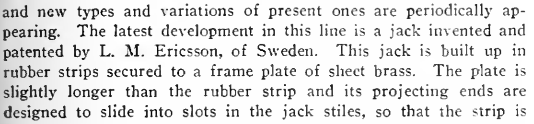

FIG. 1.—HARDEGEN TELEPHONE CASING.

The chief novelty lies in a deparature from the time-honored means of securing receiver caps. The casing of the instrument is of punched metal with a flange left at the rim. The ear piece, of metal also, lies over this, being secured by semi-circular spring pieces which snap in behind the flange of the casing. Paul Hardegen, of Berlin, is the patentee of this instrument.

TRANSMITTER DISINFECTING DEVICE.

A new type of transmitter disinfecting device is that of C. Bravi-Bertini, of Perth Amboy, N. J. This consists of a sprayer in the transmitter fed with disinfectant solution from a small pump which is driven by a linkage secured to the switch hook.

TELEPHONE REPEATER.

The telephone repeater has received still further developments at the hands of Merritt Gally, of Brooklyn. Mr. Gally's earlier work in this direction has been noted in these columns and doubtless his type of repeater will be recalled. His latest work, which is covered by two patents recently issued, is along the same lines, dealing with a bipolar magnet form of his repeater and the circuit best suited to its operation.

RECEIVER SUPPORT.

Another receiver support has been patented. This time means are provided for the automatic return of the receiver to the hook. The receiver support may be deflected in a horizontal direction by the ear of the user and becomes locked in this position. This movement of the supporting arm switches the circuit to the talking condition. If the arm be not restored by the user, central may send a current over the line and through the agency of an electromagnet and release pin, the telephone is allowed to return to the normal position.

AUTOMATIC SYSTEM.

An automatic exchange apparatus, a modification of earlier work, has been jointly invented by Messrs. J. K. Norstrom and J. J. Brownrigg, of Chicago, the patent which they have obtained being assigned to the Globe Automatic Telephone Company. The most interesting feature of this new system lies in the busy test apparatus. This is a relay in series with the subscriber's instrument and located on his premises. In case a desired line is busy the circuits are such that the busy relay at the calling station opens the talking circuit of this station until such time as the receiver has been momentarily at least returned to the switch hook and the switching devices thereby returned to the zero position.

ANOTHER CABLE SUPPORTING CLIP.

This week we have again for consideration a cable supporting clip. This is clearly shown in Fig. 2. It comprises the now usual zinc

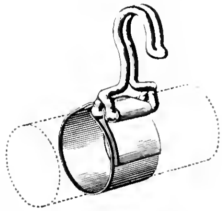

FIG. 2.—VILLARD AND COPELAND CABLE HANGER.

cable-encircling strip and a bent wire supporting hook. In this instance a double form of hook is used so shaped that not only is a locking of the tape about the cable obtained, but the weight of the cable serves to keep the tape tight. Messrs. R. H. Villard and H. P. Copeland, of Jersey City, are the joint inventors of this clip.

A Memorial to James Watt.

A most interesting and laudable movement has just been set on foot by Mr. Andrew Carnegie—ever foremost in good works—namely, to erect a memorial statue at Greenock, Scotland, on the site of the humble cottage in which James Watt, creator of the steam era, was born. The American Committee of the James Watt Memorial has Mr. Carnegie as its chairman and Mr. Theodore Dwight as its secretary and treasurer, with offices at 99 John Street, New York City. The circular just issued states that for the object named: "Subscriptions of small amounts are being solicited in many countries, as it is felt that the memorial should represent the contributions of the thousands who know and appreciate what the invention of the steam engine has meant to the material progress of the world. Should you desire to associate yourself with this movement, kindly send five dollars, or less, and accompany the contribution with your autograph on the enclosed slip. The later is desired for transmission to Greenock to show the number of the American contributions. Our country has, probably, been the greatest beneficiary of Watt's labors, and the committee hopes that the response from the United States will exceed that of any other country in point of numbers, as the number of subscribers is a greater tribute than the amount subscribed."

A great deal of interest is being taken in the project here and the committee formed under Mr. Carnegie comprises Albert R. Ledoux, president American Institute of Mining Engineers; Ambrose Swasey, president American Society of Mechanical Engineers; Charles Hermany, president American Society of Civil Engineers; Bion J. Arnold, president American Institute of Electrical Engineers; Chas. F. Scott, Westinghouse Electric Manufacturing Company; John H. Converse, president Baldwin Locomotive Works; Charles Allis, past president Allis-Chalmers Company; Charles Wallace Hunt, president C. W. Hunt & Co.; S. R. Calloway, president American Locomotive Company; R. A. McKee, International Union Steam Engineers; John C. Kafer, Engineers' Club, New York; J. D. Farasey, American Boiler Manufacturing Association; C. L. Salmons, Brotherhood of Locomotive Engineers; J. J. Hannahan, Brotherhood of Locomotive Firemen; W. J. Gitthorpe, Boilermakers and Iron Shipbuilders of America; C. L. Shamp, International Brotherhood of Stationary Firemen.

Indiana Independent Toll Line Association.

Several independent telephone men from northern Indiana and southern Michigan held a meeting in South Bend, Ind., on February 27 and organized the Northern Indiana and Southern Michigan Toll Line Association. The delegates represented a territory in which there are 15,000 independent telephones and 2,000 or more miles of toll lines. That city has been chosen as headquarters for the clearing house. The officers are: Theodore Tharward, manager of the clearing house; J. K. Johnson, secretary and treasurer. C. A. Reeves, J. S. Scott and C. R. Stoops and the officers compose the traffic committee which will perfect plans. The cities in the combination and the number of telephones in operation are: South Bend, 520; Elkhart and Goshen, 1,742; Michigan City, 750; Knox and Hamlet, 200; Winamac and Kewanna, 350; Makarusa, 175; Millersburg, 785; Dunlap, 150; Warsaw, 400; Plymouth, 300; Rochester, 430; Bremen, 136; Nappanee, 275; Millford, 276; Columbia City, 900; Silver Lake, 125; Star Point, 200; Argus, 65; North Judson, 50; Teegarden, 105; Bristol, 100; Lagrange, 1,600, and Benton Harbor, Mich., 1,575.

CURRENT NEWS AND NOTES.

HIGH TENSION MEETING IN CHICAGO.—The Chicago branch of the American Institute of Electrical Engineers will hold a meeting March 18 to discuss the subject of high-voltage lines.

CANAL TOWING.—A bill has been introduced in the New York Legislature providing that no permit to conduct electric towing experiments shall be granted by Superintendent Boyd for a stretch of canal over five miles long or for a period exceeding three years.

OPENINGS IN JAVA.—Mr. B. S. Rairden, of Batavia, Java, writes: "I believe there is a good opportunity for some enterprising American company interested in electrical material to make good connections here, although it must be prepared to fight German competitors, who are, I am so informed, largely interested in the electrical companies established in Batavia, etc."

TESTING OYSTERS FOR PEARLS.—A new use for the Roentgen rays is announced from Paris. M. Dubois has just read a paper before the Academy of Sciences, which shows that it is possible, by means of the Roentgen rays, to examine the living oyster, without in any way injuring it, and to ascertain whether or not it contains a pearl. If it contains only a tiny pearl the oyster is returned, and is allowed to live until the disease has sufficiently advanced.

ELECTRODE FOR ELECTROLYTIC PURPOSES.—A patent granted on March 1 to Mr. G. J. Atkins, of Tottenham, England, refers to details of construction of a carbon electrode. The current is introduced through a metallic sheet, which is covered by the carbon electrode. Since, however, carbon is always porous and the electrolyte would pass through the pores and attack the metal, the inventor interposes between the carbon and the metal a conducting but water-proof substratum made of finely divided carbon mixed with mineral lubricating oil.

CARBON RESISTANCE.—A patent granted on March 1 to Mr. G. I. Leonard, of Pasadena, Cal., refers to the construction of a plumbago resistance. A sheet of asbestos is coated on both faces with plumbago, applied in the state of a paint or paste with water and sufficient sugar to adhere to the support. The coating is made so thick that the resistance is somewhat higher than desired; after the plumbago is dried it is treated by frictional or rubbing pressure by a scraper or roller until the resistance is brought down to the desired value. The resistance is claimed to remain constant.

METHOD OF FORMATION OF STORAGE BATTERY PLATES.—In a patent granted on March 1 to Mr. O. Frank, of Detroit, Mich., the inventor proposes to treat the lead plates in an aqueous solution of 5 per cent. sodium sulphate and 0.7 per cent. potassium chlorate with a current of 1 amp. (the size of the plates being not given) for 50 hours at about 20° C. The plates are then washed in distilled water and the positive plates are placed in a weak solution of sulphuric acid and used as negatives against positives of lead, the current being "2 amp. for 50 hours." The plates are then washed and dried at a temperature of 300° C.

WIRELESS TELEGRAPH AND WEATHER.—The special correspondent of the New York *Times* cables as follows: "I will mention in this connection a memorial soon to be forwarded to Parliament by the fishermen of Mousehole and Newlyn, who want the weather changed and think the change can be brought about by act of Parliament. It is the candid and deliberate judgment of these fisherfolk that the Marconi wireless telegraph station located near them is the cause of the deluges that are descending on them. 'Take it away,' they say in their memorial to Parliament. Somebody will have to tell these poor petitioners that they are no worse off than the rest of Great Britain, for the whole country is watersoaked."

TAXING CANADIAN POWER.—Assemblyman Remsen, of Brooklyn, has introduced a measure in the New York Legislature which, if passed, he says, will produce $150,000 in revenue for the State. It puts a tariff of $2 on each electrical horse power produced in a foreign country and transmitted, sold or furnished to concerns in this State. It applies, of course, to Canadian concerns. There are a couple of power concerns at Niagara Falls, soon to be put in operation, which propose to furnish electricity for power in this State, and another at Cornwall on the St. Lawrence. Mr. Remsen proposes to tax them heavily. Failure to comply with the proposed law will subject any concern doing business in this State to a forfeiture of its charter and a fine of $100 a day.

A CURIE LECTURE.—Special correspondence to the *New York Times* from Paris of February 23 says: "M. Curie's promised lecture on radium drew vast crowds to the Sorbonne one evening this week. Although the hall in which the world-famed chemist was to speak is built to seat 3,000 persons, numbers who had stood for hours at the door in the Rue des Ecoles were finally turned away, every corner available being occupied by a deeply interested crowd. When the lecturer appeared upon the platform with Mme. Curie they received a magnificent ovation, and every word M. Curie spoke was followed with the closest attention. His account of the work done by M. Becquerel upon uranium, which formed the starting point for his own and Mme. Curie's experiments, was very clearly given, and his lecture was illustrated by tests of the properties of the newly discovered metal. In one series of experiments M. Curie demonstrated that radium emits three sorts of rays, two of which give off such powerful electric emanations that they cause phosphorescence and produce perpetual motion. Then, plunging a tube of radium into liquid air, M. Curie demonstrated in the darkness of the hall that it was a light-radiating body, and that it also gave out heat."

METER.—Four patents for details on electric meter construction were granted on February 23 to Mr. Thomas Duncan. In the first patent a construction is described by which an ordinary integrating meter is associated with a supplementing measuring mechanism which is operated by the main measuring mechanism. The meter with the main measuring mechanism may be located at a somewhat inaccessible place, while the supplementary measuring mechism is placed in a more convenient situation, for instance, in the library or office of the consumer. To allow recalibration, step-by-step adjusting means are provided in combination with supplementary field windings for effecting additive or counteracting torque. The second patent relates to motor-meters, suitable to be used on circuits of different voltages. This is effected by using an auxiliary field winding of which more or less may be switched into the circuit. He also describes details of construction by which he is enabled to polish readily the commutators and brushes of commutator-motor meters, without disturbing the tension adjustment of the brushes. The third patent relates also to details of construction of motor-meters and refers especially to the construction of the spindle bearing point, the manufacture of the spindle in three parts, and the construction of the upper bearing. The fourth patent again refers to the construction of the bearings. In order to render the jewel posts incapable of assuming any except predetermined positions with the meter bases, he relieves the posts of any threaded engagement with the remainder of the meter structures.

IOWA ELECTRICAL ASSOCIATION.—The Iowa Electrical Association will hold its convention this year at Des Moines, Iowa, April 13 and 14. W. S. Porter, of Eldora, is secretary.

VERMONT ELECTRICAL ASSOCIATION.—The annual meeting of the Vermont Electrical Association was held at Rutland on February 24, about 40 members being present. At the evening session Mr. F. J. Vaughn gave an address on "Central Station Meters." There was a display of electrical supplies. The officers elected for the ensuing year are: President, M. Patterson, of Fair Haven; first vice-president, E. D. Blackwell, of Brandon; second vice-president, E. E. Gage, of St. Johnsbury; secretary and treasurer, C. C. Wells, of Middlebury; chairman of executive committee, Frank Barney, Jr., of Springfield.

RADIUM IN TEXAS.—With regard to the recent reports of the discovery of radium-producing minerals in Texas, a correspondent in that State writes that the Nernst Lamp Company is mining rare earths in the locality known as Barringer Hill, which is situated 11 miles from Kingsland, Tex. This region yields gadolinite and five other new and rare minerals. The mining of yttria ore on a large scale, it is stated, gave rise to the reports that radium was being sought. It is stated that the Nernst Lamp Company is trying to purchase more land containing the earths and minerals which it utilizes in the manufacture of its lamps, but the owners have raised the prices to almost prohibitive figures. It is asserted by representatives of the lamp company that the gadolinite which it is mining does not contain radium or radioactive properties. The landowners say, however, that this statement does not agree with the reports of disinterested scientists who have recently conducted tests and examinations of the mineral. These assert that the earths possess a greater amount of radioactive properties than those of any other known region in the world.

SELECTIVE SIGNALING IN WIRELESS TELEGRAPHY.—Two patents were granted on February 23 to Prof. Reginald A. Fessenden. The first relates to a new method of tuning the sending and receiving stations to the same frequency. Electric tuning is efficient, but requires a great deal of care in its operation. Prof. Fessenden prefers, therefore, mechanical tuning. His method is essentially as follows: At the transmitting station electromagnetic waves are generated with a certain predetermined frequency—say, 2,000,000 per second—in groups of a lower frequency—say, 126 per second. For this purpose an induction coil with spark-gap may be used in connection with a make-and-break mechanism for the induction coil actuated by a tuning fork operative at the group frequency of 126 periods per second. At the receiving station the wave-responding device is connected to an indicating mechanism responding only to the group frequency 126. Such a device may consist of an electrically-operated tuning fork torque attached to a telephone tuned to the group frequency 126. Thus, unless the tuning fork or telephone at the receiving station is tuned to the frequency 126, no indications or signals will be produced. Of course, different modifications of this method and combinations are quite feasible. The second patent granted to Prof. Fessenden relates to a device for preventing disturbances from another station in the neighborhood, so that stations may be worked simultaneously while situated close to each other. For this purpose he provides, besides the main conductor of the system, second or auxiliary conductors. They are so proportioned that the effect on the main conductor, of waves emitted from the disturbing station, will be opposed and neutralized by the effect of the disturbing waves upon the auxiliary conductor.

LETTERS TO THE EDITORS.

Alternating Current Commutating Motors.

To the Editors of Electrical World and Engineer:

SIRS:—The question of priority of invention raised by the letter published on page 327 of the ELECTRICAL WORLD AND ENGINEER of February 13 should be considered from the two following points of view: 1st, validity of my patents; 2d, scientific discoveries involved.

Referring to the first point of view, I do not need to show in these columns the novelty of the dispositions described in my United States patent applications, since this matter is to be decided by the United States Patent Office.

Referring to the second point of view, the old United States patent, 476,346, evidently does not concern in any manner the phenomena which I have recently discovered and pointed out, and which alone form the basis of the conception of my series compensated motor as described in several publications. Those phenomena are: (*a*) The disappearance of self-induction in an armature with commutator and short-circuited brushes when running in the vicinity of synchronous speed. (*b*) The induction by such an armature of a rotary field at synchronous speed, if it is revolved in a stator without any magnetic axis of symmetry. (*c*) Perfect commutation at brushes under the above conditions; and, furthermore, (*d*) The screening effect of short-circuited brushes for the ampere-turns of the stator in which the armature is revolved.

The last paragraph of my letter published in your issue of March 5 may lead to a misunderstanding. In fact, the power factor of a repulsion motor is, *for the same air-gap*, much greater than that of a single-phase induction motor. The formula which I have published on the subject of the repulsion motor (*Elektrotechnische Zeitschrift*, 11 June, 1903) proves that the magnetizing current taken by a repulsion motor without load amounts to only half of the current taken by the corresponding single-phase induction motor. (The current corresponding to a zero load in a repulsion motor is obtained by making $\Theta = 0$ in my formula, giving the current taken by the motor at synchronous speed.)

But as a motor for tractive purposes must have a considerable air-gap, the power factor of a repulsion motor for traction approaches that of an ordinary single-phase induction motor.

It is only by using low frequencies, as I have pointed out in the German article above referred to, that it is possible to obtain $\tan \phi = \frac{1}{2}$; that is, $\cos \phi = 0.895$.

NEW YORK. MARIUS LATOUR.

Thawing Out Water Pipes Electrically.

To the Editors of Electrical World and Engineer:

SIRS:—Seeing an article in the February 13 number of your paper, I take the liberty to call your attention to the fact that Mr. Greene, of Altoona, Pa., gives the credit of thawing out water pipes electrically to Messrs. Jackson and Wood. I wish to state that the scheme originated with Frank H. Soden, of Chicago, in the winter of 1898. It was over a year, I believe, before Prof. D. C. Jackson, of the University of Wisconsin, came out with articles claiming that he was the one who first worked it out successfully, and originated the scheme. Furthermore, at the time Mr. Soden hit on his scheme and made it work he applied for a patent, but the Commissioner of Patents would not grant him one, claiming it was too simple.

At the time Mr. Soden demonstrated the practical use of thawing out water pipes by electricity, all of the daily and electrical papers in Chicago had great accounts of it, showing cuts and describing it at length. He had to go to nearly all of the managers of power plants in Chicago to ask permission to try his scheme. They all laughed at him except the Commonwealth Electric Company, on the South Side. It was there he demonstrated the feasibility of thawing out frozen water pipes by electricity.

Mr. Soden is a man of great ability, and was one of the earliest engineers with the old Thomson-Houston Company. He is at present at Pony, Mont., with an electrical process of treating ore, for which the Pony Electric Light Company, of which I am manager, is furnishing him all the current needed gratis, as well as a stamp mill.

PONY, MONT. E. R. AVERY.

Carbon Resistances.

To the Editors of Electrical World and Engineer:

SIRS:—Your issue of February 20 contains in the Digest news, under the heading, "Units, Measurements and Instruments," "Carbon Resistance, Gray," a description of a high resistance made by depositing soot on a glass plate or some other insulating surface. Johnson & Phillips, of Charlton, England, used to make just such resistance when I was a pupil with them away back in 1879. I believe they stopped manufacture, because the soot so deposited had a tendency to crack whenever the glass expanded and so make an open circuit. I think the Nalders, also of England, make a similar kind, but their resistance is set to 1,000,000 ohms, or whatever is required, while the older ones were kept to whatever they measured at first.

Curiously, only last month while I was down in Philadelphia, I suggested the same thing to a foreman of an electric construction company, who wanted a cheap high resistance, to make tests for insulation on completed lines.

WILKESBARRE, PA. E. W. STEVENSON.

Individual Motor Drive.

To the Editors of Electrical World and Engineer:

SIRS:—Your issue of February 20 contains in the Digest of Current Electrical Literature an abstract from an article by Cooper on "Individual Motor Drive," published in full in the current number of *Cassier's,* and also essentially in your convention issue of last June 6. That part of the article covered by the abstract treats essentially of certain rules and deductions laid down by Mr. Cooper for determining the proper size of motor to use in accordance with the methods of speed control adopted. These rules are based primarily upon a certain assumption of Mr. Cooper's, with which many electrical engineers cannot agree. Mr. Cooper's rules, moreover, are being broadly published as established facts by numerous technical and engineering publications. It would appear proper, therefore, to have the leading publication of electrical engineering discuss this article and put the same in a clearer light before the public. If it can be shown that Mr. Cooper's premises upon which he bases his deductions are wrong, or at least not fully proved, his rules will fall to the ground.

In discussing the effect of weakening the field of a motor, Mr. Cooper states as follows: "If it is desired to increase the speed 100 per cent. by field weakening, one must have 100 per cent. margin for sparking at normal speed if the motor is to carry full load at the increased speed." He then jumps to the conclusion, without giving the slightest reason, that in order to obtain this necessary 100 per cent. margin for sparking it is absolutely necessary to double the size of the motor. Nobody will disagree with Mr. Cooper that this method will accomplish effectually the elimination of sparking, and that it is a most excellent one to adopt by those who look with disfavor upon the variable field method of speed control. But is this fair? Is it good engineering or necessary to go to such extremes as this? It is right on this assumption that proof is asked for and found wanting.

Let us get clearly before us what causes sparking with a weakened field, and see if we can find any logical reason for Mr. Cooper's bold jump to conclusions. The magnetic field, due to field winding, and the magnetic field, due to armature winding, make an angle with each other, and the position of the resultant field created thereby shifts relatively in accordance with the relative magnetic strength of the field and armature. If the field magnetism is weakened, the armature magnetism remaining the same, the resultant field will tend to approach more nearly the direction of the field produced by the armature winding when acting alone. This tends to produce sparking by retarding the neutral position back of the brushes. The converse is also true that when a motor is running under light load with full field, the resultant field will then advance towards the direction of the field produced by the field winding when acting alone. This condition also tends to produce sparking at the commutator by moving the neutral point ahead of the brushes. Sparking under this condition is not noticeable, however, chiefly because the quantity of current flowing is small. The destructiveness of a spark is measured by the product of the current into the electromotive force producing it.

Sparking on the commutator is caused by cutting in and out of the line circuit each one of the coils on the armature, as its commutator segments pass under and out from the brushes. The commutator segments connected to each armature coil cause the coil to become short-circuited on itself when its segments pass under the brushes. Each coil will consequently at that time have generated in it an electromotive force which will cause current to flow through the coil in a direction determined by the relative position of the resultant field set up by the combined effect of the field and armature windings. If the armature winding predominates, the current will flow in the short-circuited armature coils in the opposite direction to that of the applied current taken from the lines. If the field winding predominates, the current will flow in the same direction as the line current, and if both windings are such as to bring the coil into the neutral field when said coil is short-circuited by the brushes, no electromotive force will be induced and no current will flow in the coil. It is only under the first conditions, however, that sparking is reduced to a minimum, namely, when current is actually caused to flow in the coil in the opposite direction to that of the line current. When the segments pass from under the brushes, current will then be flowing in the same direction as the line current, since this reverses in every coil as it passes from under the brushes. If this current, therefore, had not been previously created in the coil, its self-induction would resist instantaneous reversal, and the current would largely shunt directly across the segments and produce destructive sparking. This condition, of course, would be still further aggravated if current was caused to flow in the short-circuited coils in the same direction as the line current before the segments of the coils pass from under the brushes. Sparking is still further effected by hysteresis, or the lagging behind of the reversals of magnetism in the armature discs. It is apparent that the effect of hysteresis will increase directly with the armature speed. It seems possible, however, to take advantage of this increased hysteresis at the higher speeds and utilize it to assist in offsetting the effect of a weakened field in increasing the tendency to spark. The effect of weakening the field is to increase the speed and also to allow the armature winding to pull the resultant field back of the non-sparking position of the brushes, while the effect of hysteresis, as the speed increases thereby, is to cause the reversal of magnetism to lag behind, and thus, to a certain degree, counteract the effect of the increased tendency to spark caused by the relatively predominating influence of the armature windings, thus preventing the inducing of too great a current in the short-circuited coils, which otherwise would produce sparking. In a proper design, then, the above two causes which tend to shift the sparking point of the brushes may be so nicely balanced as to allow a very large variation of speed by field weakening. Of course, there are many other details of design to be carefully worked out, and the above theory is merely set forth to show that even the usual theoretical conception of the cause of sparking under variable field conditions is not so difficult of a practical solution as might otherwise appear.

Mr. Cooper goes on to say "that the limit of power of a motor operating under full field strength is the heating effect of the current flowing through the armature, but the limit of power of a motor with a weakened field is the sparking at the commutator." With the cause of sparking clearly before us, it would seem as though these two statements contradict each other. Abnormal currents in the armature produce a similar distortion of field as results from weakening the field magnetism, and the resultant sparking is far more destructive on account of the relatively larger currents producing them. Well-designed motors will not spark seriously at their commutators when carrying double their normal load at full field strength, and their limit of power, as Mr. Cooper states, is the heating effect of the armature current. Such motors practically have a 100 per cent. margin for sparking. Why is it not then perfectly practical to build motors that will develop their full rated horse-power at double their normal speed, with a weakened field, without undue sparking? The current producing the sparking in the latter case is only half as great as in the first, and the cause of the tendency to spark is, perhaps, no greater in one case than in the other.

Theoretically speaking, weakening the field of a motor merely weakens its torque or turning effort, and as the speed increases in direct proportion as the decrease in torque, the horse-power capacity of the motor remains constant within reasonable limits of field weakening. It is certainly true of a great many makes of motors now on the market that they will actually develop the same horse-power at double their normal speed with weakened field, but most of them will spark badly at the commutator on the higher speeds when transmitting their rated horse-power, simply because they were designed to run at a constant speed. It is true, however, that motors can now be purchased that will develop their full rated horse-power over a speed range of 4 to 1 by field weakening, without abnormal sparking, over this entire range of speed. A quotation was received a few days ago from one of the large motor manufacturers for furnishing a suitable frame capable of developing 15 hp at 900 r.p.m. under full field strength, but so wound specially that it would develop 5 hp at 300 r.p.m. with full field and 5 hp at 1,200 r.p.m. with weakened field, without undue sparking at the commutator. This manufacturer consequently starts with a slow-speed motor, capable of developing 5 hp *only* at 300 r.p.m., and makes this motor continue to deliver 5 hp at any speed up to 1,200 r.p.m., without injurious sparking at the commutator.

Mr. Cooper's rule for determining the size of a motor to fill the above specifications reads as follows: "The relative size of motor, as referred to the maximum speed, is as the square of the speed variation when using field regulation." This means that if a 5-hp motor is capable of developing sufficient horse-power at its maximum speed of 1,200 r.p.m. under full field strengh, it will be necessary to employ a size of frame equal to 5 multiplied by 4 square, or 80 hp, in order to develop satisfactorily 5 hp of work over the entire range of speed from 300 to 1,200 r.p.m. That is to say, under Mr. Cooper's rule it would be necessary to use a motor of four times the size as the one guaranteed to do this work in the quotation cited above. Whether or not Mr. Cooper's deductions are practically correct depends entirely, then, upon *who builds the motor.*

In the light of the above statements of theory and fact Mr. Cooper's rules for determining the size of motors are apparently limited to an attempt to obtain a variable speed from a motor distinctly designed to operate at a constant speed.

If motor users will take the trouble to purchase motors designed to operate at variable speed under variable field strength, guaranteed not to spark under full load conditions, at all speeds, Mr. Cooper's rules will be found entirely inapplicable, and the following may be substituted in their place:

(1) The total range of speed using both variable voltage and field regulation will be directly proportional to the range of voltages multiplied by the increase due to field weakening.

(2) The change of horse-power capacity will be directly proportional to the change of voltage on the armature.

(3) The horse-power capacity under variable field strength will remain constant.

(4) The relative size of motor as referred to the maximum speed will be directly proportional to its speed variation when using variable voltages.

(5) The relative size of motor as referred to the maximum speed will be directly proportional to its speed variation when using field regulation.

(6) The size of motor required to develop a constant horse-power over the entire range of speed is *identical,* whether the multiple voltage or weakened field system be used, or any combination of the two.

MILWAUKEE, WIS. H. H. CUTLER.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

DYNAMOS, MOTORS AND TRANSFORMERS.

Voltage Regulation in Alternating-Current Systems.—MEYER.—The first part of a paper read before the Liverpool Engineering Society. He discusses the inherent regulation of generators which is usually defined as the percentage increase in the terminal voltage when full load is taken off the machine, the excitation remaining unaltered, and due allowance being made for variations in speed as caused by the engine regulation. In England sometimes another definition is used, namely, the percentage fall in voltage upon throwing on full load, keeping speed and no-load excitation constant. This definition, however, leads to entirely different figures and should be abandoned. To get close regulation of a machine the ratio of field ampere-turns to armature ampere-turns should be as large as is possible with an economic design. A low armature self-induction is useful by reducing the inductive drop in the armature conductors. For this purpose the winding has to be properly subdivided and so arranged that at the same time the effect of the end connections is minimized, which is of particular importance in machines with a large pole pitch and a small width. The leakage between poles should be as small as possible. For this purpose one has to choose short poles, a large pole pitch and the pole arc in maximum 66 per cent. of the pitch, although these requirements lead to a larger diameter and consequently to a more expensive design. The leakage coefficient is further covered by the length of the air-gap and the iron densities in the machine and increases with the load in about the same proportion as the excitation. The magnetic densities in the poles should be high, so as to introduce a saturated part in the magnetic bath, which will limit the rise in voltage when the load is taken off the machine. Densities of 110,000 to 115,000 lines per square inch are here quite allowable, provided the designer knows exactly the leakage coefficient of his machine and the quality of his material. It is advisable to differentiate between machines which are intended to work on unity power factor or on a power factor, say, not below 0.90, and those intended to work chiefly on a low power factor. In the latter case it is better to use lower densities than mentioned above, although this leads to a more costly design. Finally all parts in the machine should be so proportioned that the resultant wave shape of e.m.f. and current resembles as closely as possible a sine wave. Some of these points are illustrated by the author by means of diagrams and tables. Not only the size and cost of alternators are unfavorably influenced by too close a regulation, but the efficiency and stability of regulation are equally affected. A reduction in efficiency from 1 to 1½ per cent. may be expected when changing the machine with an inherent regulation of say 7 per cent. into one with 4 per cent. without resorting to saturation. In regard to stability of operation it is noted that very close regulating machines—due to their low armature reaction and self-induction—have a large short-circuiting current. With close regulating machines working in parallel large cross currents and a considerable exchange of energy between the bus-bars and the generators take place if the cyclic irregularity inherent to all reciprocating engines is not kept to a very small amount by means of an extra large fly-wheel effect, which, of course, increases the cost of the plant. But even then troubles in parallel may readily occur with too close regulating machines due to the natural period of the alternator becoming such as to introduce the danger of resonance with the forced oscillations of the engine. Large currents on short-circuit also tend to cause troubles in plants as required for rolling mills and mining works, where, due to the rough service, heavy overloads and even short-circuits may frequently occur. While within the above discussed limits a close regulation should be aimed at in all normal machines, there are also cases where a poor regulation is essential. This refers to alternators for constant power or constant current work, as required for certain electrolytic processes where the current is used for feeding an arc.—Lond. *Elec.*, February 19.

Sparking Dynamo.—BROWNE.—An account, from the records of an electrolytic refinery, of the troubles experienced for several weeks with a sparking dynamo. It was afterwards traced to the fact that several of the electrolytic tanks had been cut off since they were not properly working. This changed the total line voltage with a resulting weakening of the magnetic field and consequent sparking at the commutator. A diagram is given of a switch by which four different methods of field excitation are possible; self-excitated series and multiple field and separately excited series and multiple field, so that under all conditions of operation the field of the dynamo may always receive the proper exciting current.—*Electrochem. Ind.*, March.

REFERENCES.

Asymmetric Attraction of the Rotor in an Induction Motor.—REY.—The author first gives the theory of the subject and develops a formula for the attraction, which he then applies to a numerical case. His figures indicate that the asymmetric attraction may have important consequences. In the case of motors running at considerable peripheral speeds such as those used for traction or for operating rotary engines, centrifugal pumps, etc., these efforts combined with the weight of the movable parts may create dangerous vibrations. It is necessary to take them into account in the calculation of the pieces, since absolute symmetry can scarcely be realized in practice and the wear and tear gradually introduces a certain eccentricity.—*L'Eclairage Elec.*, February 20.

Single-Phase Series Motor.—NEWBURY.—An article in which, by the aid of diagrams, the author explains the operation of the alternating-current series motor. While in general it works on the same principles as the direct-current series motor, the following phenomena characterize the alternating-current motor; an e.m.f. generated in the armature winding by the alternating magnetic field, in addition to the e.m.f. generated by the rotation of the armature; a local current circulating in the armature coils short-circuited by the brushes due to the e.m.f. just mentioned; an iron loss occurring in the entire magnetic circuit, due to the alternating magnetic field; an active e.m.f. existing between the turns of the field coils, what may be called the counter e.m.f. of the field coils. The author gives the voltage diagram of the motor.—*Elec. Club Jour.*, February.

Single-Phase Commutator Motors.—Blanc.—An illustrated note supplementing the summary of various types of single-phase commutator motors, recently given by Osnos.—*Elek. Zeit.*, February 18.

Repulsion Motor.—Osnos.—An article illustrated by diagrams in which the author develops a complete theory of the repulsion motors of Atkinson.—*Zeit. f. Elek.* (Vienna), February 14 and 21.

Lights and Lighting.

Arc Between Metallic Oxides.—Stark.—An account of experiments in which he found that under certain circumstances an arc is more easily established between metallic oxides than between the metals themselves. He uses a vacuum tube in which the main current passes between the anode and the cathode and produces the ordinary glow phenomena, while the secondary current passes between electrodes at right angles to the primary electrodes, and is extinguished as soon as the main current is interrupted. At a pressure of over 50 volts and a vacuum of less than 0.5 mm., the presence of a film of metallic oxide, or of a few fragments of it, facilitates the production of an arc between the secondary electrodes. The author gives the following explanation of this effect: The lines of electric force proceed straight from the anode to the cathode, but if the latter bears a fragment of metallic oxide, they curve round it and enter the cathode at some other point. Nevertheless, the positive ions, having acquired a certain amount of momentum, go straight on and impinge upon the oxide, thus increasing its temperature and causing it not only to conduct electricity, but to evolve electrons in large quantities. Wehnelt has already shown that metallic oxides project more electrons than pure metals at high temperatures, and hence the arc, which requires a liberal supply of electrons, is more easily formed at the oxide than at the pure metal. At atmospheric pressure the author obtained a small arc between a carbon anode and a cathode of thorium oxide at a pressure of 1,800 volts and with a current of 7 milliamperes. The anode remained quite dark.—*Phys. Zeit.*, February 1; abstracted in Lond. *Elec.*, February 19.

Arc Lamps Giving Illumination in a Certain Direction.—Richter.—An account of photometric measurements of arc lamps giving light in a certain direction. For this purpose the two carbons were placed with their axles parallel to each other, but in such a way that they did not form one straight line, the one axle being parallel to, but laterally displaced from the other.—*Elek. Zeit.*, February 4.

Power.

Turbines for Low Falls.—Steiger.—An abstract of a paper in which the author draws attention to the prejudice which exists against the utilization of water power with low falls, and which is traceable to many unsatisfactory installations of absolutely unsuitable turbines. The demands of the generation of electricity by water power, such as high speed, rapid regulation and concentration of large power in one unit, have influenced very considerably the art of building turbines. In the first place, the desire for high speeds has led to a more general adoption of radial-flow turbines of which the inward-flow is preferable, being the more efficient. An example of radial outward-flow turbines was cited, with the special reasons which had led to their adoption in one case of a relatively low fall and the manner in which a quite satisfactory efficiency had been obtained from this otherwise less efficient type. One new type, the cone turbine, was referred to as taking the place of the so-called "mixed-flow turbine," with a view to obtain a high speed under low falls, even for large units. With special regard to electrical requirements, reference was made to the arrangement of several wheels on one common turbine shaft, vertical or horizontal, giving a few instances of the vertical arrangement which, in certain circumstances, was particularly advantageous, as the weight revolving on the footstep could be entirely balanced, and so the loss of power by friction was reduced almost to nil. The necessity of placing the footstep of a turbine in an accessible position was alluded to.—Lond. *Elec.*, February 19.

Electric Power for Rolling Mills.—Köttgen.—A long paper read before the Society of German Iron Metallurgists. The author discusses at length details of the equipment of electrically-driven rolling mills. Either the direct-current or the three-phase-current system is applicable. By field regulation in the former case or by inserting resistances in the rotor circuit in the latter case, the speed can be changed. In order to make use of the fly-wheel effect of the large masses used in rolling mills, the motors should show some reduction of number of revolutions when load is thrown on. If the electric current is supplied from a lighting network, care should be taken to provide means so that the fluctuations of load do not react upon the lighting network. In such cases an intermediate converter plant either with a heavy fly-wheel or with a storage battery would be used. The author discusses at some length the economy of generating the electric power by using the blast furnace gases for driving gas engines coupled with dynamos. If the rolling mill is very near the blast furnaces it could, of course, be driven directly by gas engines; but if it is at some distance it is preferable to use the gas engines for generating electrical energy. He gives an estimate of cost of operation of a rolling mill with a yearly output of 300,000 tons under such conditions, and finds that the cost of operation per year would be about $20,000 with the electrical system, against $52,000 to $90,000 with a steam plant. Since the first cost of installation of the electrical plant is estimated as about $90,000, it is seen that this cost will be covered within a few years by the saving in the cost of operation.—*Stahl und Eisen*, February 15.

Indian Railway Workshops.—A note on the recently built workshops of the Bengal-Nagpur Railway at Kharagpur, India. Three 200-kw steam dynamos generate direct current at 220 volts and three-phase current at 140 volts. Direct current for power purposes is distributed by means of lead-sheathed cables, laid in stone troughs filled in with bitumen. The lighting wires are carried overhead on porcelain insulators supported on iron poles; 110 direct-current motors, ranging in power from 1 to 50 hp, are employed for driving the machine tools, cranes, etc. Many of the larger motors may be regulated in speed in the ratio of 2:1 by means of field rheostats. Small tools are driven in groups from short lengths of shafting. Three-phase currents at 2,200 volts are transmitted by two independent overhead lines to the pump house (three miles distant) where two pumps, each capable of delivering 30,000 gallons per hour, against a total head of 165 ft., are driven by two 45-hp, three-phase induction motors.—Lond. *Elec.*, February 19.

Traction.

Slot Point.—An illustrated description of the new slot point to be used on the lines of the London County Council tramways. In conduit tramways the divergence of the two slots at junctions has always been a source of trouble, due to the fact that the merging of the slots one into the other creates an objectionable width of opening, which, with ¾-in. slots, sometimes amounts to 2 in. The narrow rubber tires of light vehicles drop into this opening, causing a very unfavorable wrench when the wheel leaves the slot. The slot tongues which are used to divert the plough are made in the form

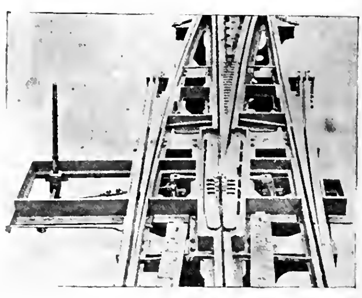

FIG. 1.—SLOT POINT.

of flat steel plates sliding backwards and forwards in resistances in the side castings. These work at a distance of 1⅝ in. from the top surface of the slot rail. On these plates a number of projections are arranged so as to come within ⅜ in. of the road surface at the fixed slot point, thereby reducing the depth at the opening by 1¼ in. The nose of the fixed slot point is tapered off to the level of the projections, so that any wheel riding on the slot tongue is easily carried on to the point. The projections are divided by radial slots, in order to clear the strengthening ribs on the long cast-steel cover. In Fig. 1 the lids of the slot points and the covers of the road boxes have been removed to show the arrangement of the slot tongues.—Lond. *Elec.,* February 19.

Single-Phase Traction.—SCOTT.—A discussion of the general features of the Lamme single-phase series motor. Large as well as small motors may now be operated successfully on a period of 25 cycles, and under certain conditions the motors may be operated on ordinary direct-current railway circuits. A feature of this motor is, in fact, its conformity to the standard type of direct-current motor. If wound for 250 volts, two in series are suitable for operation on a 500-volt direct-current circuit, and a four-motor equipment may be operated with an ordinary type of series-parallel control. Such an equipment of single-phase motors with rheostatic control may be operated either upon a 500-volt direct-current circuit, or upon a 500-volt alternating-current circuit, or upon a high-voltage trolley circuit of say 1,000 to 3,000 volts, the voltage being reduced by a transformer on the car. This enables interurban cars to be operated on direct current in cities and on altenating current across the country.—*Elec. Club Jour.,* February.

Mountain Railroad.—THOMANN.—The first parts of a detailed description of the Mendel road in Southern Tirol (which is well known to every traveler going from Verona to Tirol). This is the longest and steepest of all cable roads so far built. The road is divided into two sections. The first, from Kaltern to St. Anton (difference in level between the two ends 105 meters) is an ordinary adhesion road with 6.2 per cent. maximum grade, 500-volt direct current being supplied from a trolley wire and the rails being used for the return current. The second section has a difference of 854 meters between the levels of the two ends and is operated as a cable road with 64 per cent. maximum grade. The arrangement is that ordinarily used, one car going up while the other car runs down.—*Elek. Bahnen.,* Nos. 3 and 4, February.

Conductor Rails.—STEVENS.—Illustrations of a section of the new track on the Liverpool overhead railway.—Lond. *Elec.,* February 19.

Hamburg.—An account of the discussions which have been going on for a long while in Hamburg concerning the question whether for the city and suburban roads, traction on rails or a suspended train (as in Barmen-Elberfeld) should be adopted. The final decision was in favor of a road on rails.—*Elek. Bahnen.,* No. 4, February.

British Tramways.—A description of the Bath tramways which were recently opened. The line is equivalent to 16 miles of single track. The power house contains three steam-driven, 200-kw compound generators. The trolley system is used.—Lond. *Elec.,* February 19.

INSTALLATIONS, SYSTEMS AND APPLIANCES.

Automatic Devices.—A long editorial in which it is claimed that in view of the importance of labor-saving devices in American industries due to the labor conditions in this country, the development of automatic devices has been far in excess of the requirements of other countries and even in some respects in excess of the requirements of the United States. It is thought that every branch of electrical engineering has been attacked by the craze for automatics to such a point that a word of warning is now in place. While the use of several motor cars instead of a single locomotive is preferable, the simplest means of controlling all motors from one controller would necessitate the employment of several cables conveying heavy currents along the whole length of the train. To avoid this the multiple-unit systems have been devised and while the systems already in use apparently work well, yet a step further in the long chain of independent automatic devices would as likely as not so weaken the whole connection as to cause electric raliway engineers to return in a panic to a more primitive system. While the "remote control" switchboard is recommended to some extent, it is thought that some modern switchboard designs, especially in telephony, are bewildering in their ingenuity and perplexity. While a certain amount of automatic devices are necessary in electric works, yet it is dangerous to follow the fashion too far. The writer quotes the old saying attributed to Edison that the best automatic device is a "nigger."—Lond. *Elec.,* February 19.

WIRES, WIRING AND CONDUITS.

Electric Perforation.—KROGH.—A communication referring to the law of Baur, who gives the relation between thickness of material and perforation voltage by the following formula: $V = c\,d^{2/3}$. The present author says that while this formula gives very good results for all practical purposes, it cannot be considered as an exact law, since by testing liquid insulation materials distinct although small discrepancies from this law can be traced.—*Elek. Zeit.,* February 18.

Capacity of Conductors and Cables.—LICHTENSTEIN.—The conclusion of his article. He summarizes in a table the mathematical formulas which he has derived for the capacity of two parallel overhead conductors, of a three-phase overhead line, of a two-wire cable, of a three-phase cable, and of a concentric single-phase cable. He applies the formulas to some numerical examples.—*Elek. Zeit.,* February 18.

ELECTRO-PHYSICS AND MAGNETISM.

Radioactivity.—RUTHERFORD AND BARNES.—In a Physical Society paper Rutherford discusses the question whether the radioactivity of radium depends upon its concentration, radium bromide being used either in pure solid form or dissolved in a solution of radium chloride. He found that the radioactivity is independent of the concentration. This shows that the rate of disintegration of radium and its products is not appreciably altered by the bombardment of its own powerful radiations, and renders it probable that the conductivity of radium is, in all cases, directly proportional to the amount of that element present. In another paper, by Rutherford and Barnes, the heat emission of radium is studied. This is shown to be an accompaniment of the expulsion of α particles and the time variation of the heating effect of each of the different active products is the same as the time variation of the activity measured by the α rays. The heat emission of radium is probably due in part to the kinetic energy of the expelled α particles and in part to the energy released consequent upon the rearrangement of the components of the systems left behind after the expulsion of the α particles. The following estimation of the energy given out by radioactive bodies is interesting: One gram of the emanation radiates during its life an amount of energy lying between 2,000,000,000 and 20,000,000,000 gram calories. One pound weight of the emanation would initially radiate energy at the rate of 10,000, to 100,000 hp and would emit during its life an amount of energy between 60,000 and 600,000 hp-days. There can thus be no doubt that matter, under special conditions, is capable of emitting an amount of energy enormous compared with that realized in the most intense chemical reactions. On the disintegration hypothesis this energy is derived from the energy latent in the radium atoms and is released during the successive stages of their disintegration.—*Phys. Rev.,* February.

REFERENCES.

N-Rays.—Various papers on recent developments on this subject. Lambert has found that soluble ferments emit N-rays, especially the ferments concerned in the digestion of albuminoid matter. Meyer has found that plants emit N-rays whether they are kept in the dark or exposed to light, and that there is no difference due to the action of light. Gutton has found that the effect produced by N-rays upon a luminescent screen may be imitated by means of a non-uniform magnetic field. Charpentier has discovered two new effects of N-rays. If a strong source of N-rays is placed 4 cm. behind the top of the skull and a little above it, not only are faintly luminous objects perceived with greater brightness and detail, but in absolute obscurity a faint luminous cloud is perceived. The other new effect is the enlargement of the pupil when the conducting plate is placed over the seventh cervical vertebra.—*Comptes Rendus,* January 25 and February 1; abstracted in Lond. *Elec.,* February 19.

Velocity of Light in a Magnetic Field.—MILLS.—An account of experiments in which, as in former investigations, the method was to note the shifting of the interference bands formed by the divided portions of the same beam, one portion of which has traversed a medium in a magnetic field. He used the apparatus of Morley and Miller. A distinct shifting of the fringes was noticed and these shiftings increased with the current.—*Phys. Rev.,* February.

Electro-Chemistry and Batteries.

Conductivity of Solutions in Methyl Alcohol in the Neighborhood of the Critical Points.—Krauss.—The conclusion of his paper; he now discusses the results. Solutions in methyl and ethyl alcohol possess maxima of electric conductivity, the former in the neighborhood of 150° C. Solutions in ethyl and methyl conduct beyond the critical point, the former conducting much the better. The temperature coefficient of a solution in methyl alcohol undergoes a certain change at a critical point. The vapor of a solvent may become a very good conductor in the neighborhood of the critical point. The conductivity increases very largely for a saturated vapor as the critical point is approached, owing to increasing density of both solvent and solute.—*Phys. Rev.*, February.

Alloys of Copper and Cuprous Oxide.—Hofman, Green and Yerxa.—A fully-illustrated account of a "laboratory study of the stages in the refining of copper." The authors studied by metallographical methods the various alloys of copper and cuprous oxide and show that area measurements of enlarged micrographs of pure coppers containing less oxygen than the eutectic give good valuations of the oxygen contained. It also seems entirely feasible to make a close estimation of the percentage of cuprous oxide contained in a sample of copper by simply examining a polished surface with the microscope when once some experience has been gained.—*Electrochem. Ind.*, March.

Electrode Voltage.—Johnson.—An article in which the author gives the theory of the electrode voltage first on the basis of the principles of thermodynamics and afterwards on the basis of the osmotic theory of solutions.—*Electrochem. Ind.*, March.

Cadmium Cell.—Barnett.—An account, illustrated by diagrams, of some experiments on the polarization and recovery of cadmium cells.—*Phys. Rev.*, February.

Units, Measurements and Instruments.

Electric Units.—Bauch.—A communication referring to the recent proposal of Teichmüller, with whom he agrees in most points. He does not approve, however, his proposal to substitute the name weber for gilbert. He makes instead the following proposition: By the name gauss we indicate at present the numbers of lines of force per square centimeter as well as the m.m.f. per centimeter length. These are now two different things, and the distinction between them is not purely academical, but has practical importance. For instance, everybody who designs machines knows that we may have at the same time density of lines of force per square centimeter in air-gap = 8,000 c.g.s. units and m.m.f. per centimeter in air-gap = 6,000 c.g.s. units. If one writes this, using the name gauss in both cases one has air-gap = 8,000 gausses in one case, and in the other case air-gap = 6,000 gausses. Errors in the further calculations are then easily made. The present author suggests to call m.m.f. per centimeter, gauss, and the density of lines of force per square centimeter, weber, then one has to write in the above example air-gap = 8,000 weber and air-gap = 6,000 gausses. To use the two names, gauss and weber, for two similar units indicates that these two scientists worked jointly in many important investigations. Concerning the possible objection that the two quantities differ only by the factor μ (which is often considered as a pure number), he says that horse-power and watt also differ by a constant factor only. Nevertheless, we measure the output of a motor in horse-power and the power supplied to it in watt.—*Elek. Zeit.*, February 18.

Applications of the Oscillograph.—Morris and Catterson-Smith.—An account of some experiments in which the oscillograph was made use of for recording magnetization curves of transformers during working. The method is an application of the double oscillograph of the Duddell pattern and the device consists in passing through one of the oscillograph strips a current proportional to the magnetizing force, and through the other a current proportional to the induction density. A parallel beam of light from an electric arc is reflected from the mirror attached to the one strip, so that the reflected beam is subject to an angular vibration in a horizontal plane proportional to the magnetizing force. This reflected beam is received on one of the smaller faces of a right-angle prism placed so that its large surface is inclined at 45°. The vibrations of the beam are thus transformed into movements in a vertical plane. The light is then received on a silvered lens (acting as a concave mirror of about 18 in. radius) and focussed back on the second oscillograph mirror, so that the final reflected ray partakes of both vibrations as co-ordinates in the usual manner of B.-H. curves. The method of superposing the vibrations of two oscillograph strips in planes at angles is also applicable to the estimation of small power factors, since a straight line can only be obtained as the resultant vibration when the two waves in these strips are exactly in phase. They also made experiments on the currents in a direct-current shunt-wound motor and in a rotary converter under varying conditions of load.—Lond. *Elec.*, February 19.

REFERENCE.

Testing the Magnetic Properties of Sheet Iron.—An illustrated description of the method of Richter, used by the Siemens and Halske Co. for determining the iron losses in whole sheets, which has already been noticed in the Digest.—Lond. *Elec.*, February 19.

Telegraphy, Telephony and Signals.

Telephony.—Stosberg.—An article in which the author proposes to provide a resistance in shunt with the microphone. The resistance of a microphone when unused is about 20 ohms, and that of the primary windings of the induction coil about 1 ohm. If in this circuit two cells are used in series, each of 1.3 volts and 1.5 ohms internal resistance, the current will be 118 milliamperes, or 60 milliamperes if only one cell is used. The disadvantage is that the contact points of the carbon particles as well as the carbon surfaces of the membrane are burned. If the carbon of a microphone, which has been used for some time is investigated, it is found that it is surrounded by an ash-like powder of low conductivity. While it is impossible to increase the primary resistance, the above disadvantage may be overcome by connecting a resistance of say 60 ohms in shunt with the microphone. The joint resistance of the circuit then becomes about 16 ohms. With two cells the current becomes 161 milliamperes, of which 120 flow through the microphone resistance and 40 through the sunt resistance. With one cell of 1.3 volts, the current becomes 82 milliamperes, of which 61 pass through the microphone and 21 through the shunt resistance. He has found that the formation of sparks is thus entirely avoided and the carbon is not burned. The shunt resistance is best made of nickel wire with silk insulation, of a diameter of about 0.16 mm; 4 meters of this wire are sufficient to give the 60 ohms, and may be easily rolled up to form a ring of 5 cm. diameter. In exchanges it is preferable to use instead of the artificial resistance a galvanoscope of 60 ohms resistance. This allows the attendant to control at any time the condition of the microphone battery; it would be automatically connected to the circuit while a speech is transmitted.—*Elek. Zeit.*, February 4.

Miscellaneous.

Tests of Lubricating Oils.—Wilkens.—An illustrated paper read before the Berlin Electrical Society in which he describes methods, used by the Allgem. Elek. Ges. of Berlin, for testing lubricating oils. The author points out that for all methods of operation it is of importance that a sufficiently thick film of lubricating oil is always between the two sliding surfaces; for this purpose the oil should have sufficient consistency. For some methods of operation this is much more important than a low internal friction coefficient of the oil. For instance, in modern electric central stations with large, directly-coupled machine sets of 1,000 or more hp, it is of small account whether the few bearings in it get heated to 40° or 45° C., since the increased friction loss, due to the increased temperature, is scarcely noticeable in the fuel consumption. On the other hand, in all cases where friction losses represent a large proportion of the total power consumption, for instance, in plants with much shafting, a small increase of the friction resistance at every sliding surface will have an important influence upon the total power consumption and on the economy of operation. For this class of plants an oil of a low internal friction coefficient should be chosen. The author emphasizes the importance of the tests of the physical properties of lubricating oils, the most important properties being the internal friction resistance and the consistency of the oil. The internal friction resistance is determined by the apparatus shown in Fig. 2. K is a closed chamber filled with the lubricating oil to be tested and provided with a wheel, F, the axle of which is driven by an electric motor. This chamber communicates with two columns, $R\,R'$, which are filled about to one-half with the oil. When the wheel revolves the oil inside the spokes of the wheel moves along an outside layer of oil, which is in direct connection with the oil in the two columns. On account of friction between the two oil surfaces this outside layer of oil is set into motion and the level of the oil rises in the one column and falls in the other, until a stationary condition is reached which depends upon the speed of the wheel and the properties of the oil tested. From the difference of the levels in the two columns, the specific gravity and the speed of the wheel, the internal coefficient of the oil may be found. To test the internal friction of the oil for various temperature and speeds, the temperature of the oil is varied by means of an electric heating device and the speed of the motor is changed. A large number of curves are reproduced which were determined in this way for different oils. From the torque of the motor the consistency of the oil can be determined. If k is the torque for petroleum for a certain speed and K the torque of an oil to be tested for the same speed, then the consistency of the latter oil in per cents of the consistency of petroleum is $100 (K - k) \div K$. The results obtained by this apparatus were found to give correct indications of the suitability of an oil for certain purposes.—*Elek. Zeit.*, February 18.

American Engineering Schools.—WALMSLEY.—A paper read before the British Institute of Electrical Engineers on "Transatlantic Engineering Schools and Engineering." In comparing American with English colleges, he endeavors to show that candidates for entrance to American engineering colleges are older and better fitted to receive the training than those in England. He recommends the abolition of the premium system in English technical schools, their better equipping and staffing, more encouragement at home for graduates and wider knowledge that college training is absolutely essential. Some form of the sandwich system should be adopted.—Lond. *Elec.*, February 19.

Electric Club Journal.—This is a new monthly published by the Electric Club, of Pittsburg. The first number contains a good portrait of George Westinghouse, with an account of his life by Taylor. Other articles are abstracted elsewhere in the Digest.—*Elec. Club Jour.*, February.

Restoring Full Telephone Service in Baltimore.

Details were given recently in these pages of the great fire in Baltimore, and its damage to the various electrical services, including the telephone, which was, of course, in universal use in the burned district. The principal office of the Chesapeake & Potomac Telephone Company was destroyed and some 7,500 of its telephones were silenced by the fire. No one imagined that anything like a complete restoration would be accomplished within four weeks from the date of the fire. Not only was the St. Paul central office totally wrecked, but the building in which it was located was so badly damaged as to be entirely unfit for use.

On the Saturday night before the fire two new central offices had been opened. On the Sunday night following, while the fire was still raging, it was decided to enlarge one of the new offices which had been equipped to serve about 4,000 telephones, so as to serve over 12,000 lines. Parts of a new switchboard then in Washington ready for installation in that city were immediately shipped to Baltimore and the necessary cables were ordered from the Chicago factories of the Western Electric Company. Within two weeks the equipment for 4,000 telephones was in place and the telephones were rapidly connected. The entire installation was completed on February 29, 21 days after the fire originated.

To accomplish this men were taken to Baltimore from Philadelphia, Washington, New York, Boston and other cities. The men were organized to work in three shifts of eight hours each, and the work was pushed forward continuously day and night. A special commissary department to supply lunches and coffee was organized, and all important shipments of supplies from New York and Chicago which did not come by express were accompanied by men to prevent delays and the possibility of loss on the way.

The new switchboard is 135 ft. in length and contains 160,000 "jacks." In constructing the board 500,000 hand-soldered connections were made. Thirty-five miles of switchboard cable, containing 2,000 miles of wire, were used.

One week after the fire it was decided by the company's officers to reopen the South office, to serve subscribers in the southern part of the city below Pratt Street. The work of altering the building to accommodate a larger equipment than had previously been used there, and of installing equipment to serve about 4,000 telephones, was pushed forward vigorously, an emergency board being expressed from Chicago for this purpose. The installation was completed February 29 and put in service March 2.

The loss of the telephone company was not confined to the property actually destroyed, as its cables and lines in the burned district were rendered useless for the time being. The cable factories were set in motion, and as much as 8,000 miles of wire were made into cables, taken to Baltimore, drawn into the subways and spliced. This work was interfered with to a considerable extent by the wrecking gangs who were engaged in tearing down walls in the vicinity of the manholes.

In carrying out its plans made at the beginning of the year the company had just contracted for the erection of a three-story fireproof building 42 x 80 ft., designed for telephone use exclusively, to be located near Wolfe and East Fayette Streets. This office, when completed, will serve East Baltimore, and meanwhile subscribers in that part of the city will be connected to the Mount Vernon exchange. None of the work done in the restoration of the system is of a temporary character, the cables and equipment used being of the most modern type and the work of installation being done in the most skillful manner.

Storage Batteries Used for Thawing Water Pipes.

A novel departure in the process of thawing out frozen water pipes is reported by the Storage Battery Supply Company, of 239 East Twenty-seventh Street, New York City. We give below a description of its process as adopted recently in thawing out pipes in Borough Park, Brooklyn. President T. D. Bunce says:

"Our method consists in taking a load of storage batteries, arranged for high amperage work with variable connections, adjustable for high amperage and low voltage on large pipes and low amperage on small pipes. In the present case we supposed the service pipe, which was ½ in. in diameter, was all that was frozen, so we connected our feeders to the water main in the street and the outlet in the cellar of the party's house. The pipe was about 80 ft. long and with about 15 volts and 300 amp.; we had raised the temperature of the service pipe to about 150°, where it was exposed in the cellar.

"We continued this for about twenty minutes, but no water came, so we concluded that the main was frozen, the party being the last man on it, and as the adjacent house had a supply of water we dug another hole and connected our feeders at this point and also at the first location on the mains in the street. This main was 2-in. galvanized pipe and the distance was about 20 ft. We used a pressure of 6 volts, but do not know how many amperes were used, as our meter did not read high enough. I presume it must have been in the neighborhood of 1,000 or more. From the time we threw on our current it required three minutes to have running water in the house."

Underground Cables in Baltimore Fire.

The Baltimore fire has been the unfortunate means of settling many disputed points for the engineers of this country, and it has, among other points, emphasized most forcibly, in the minds of interested observers, the superiority of underground cables for electrical transmission of power, as compared with old overhead methods.

The Standard Underground Cable Company has installed during the past few years in Baltimore many miles of underground cable, in the municipal subway, for the Western Union, Baltimore & Ohio Telegraph Companies, the Maryland Telephone Company, the City Fire and Police Departments and the United Railways & Electric Company. The main conduit lines run the entire length of the burned district and the manhole covers were in many cases covered with piles of hot brick and stone to a depth of twenty feet.

In spite of the intense heat there is, so far as is known, not a single instance of trouble on the cables in manholes or subway except where exposed ends of cables were destroyed by the fire; and the cable system is in perfect condition to-day.

The three-conductor cables installed for the United Railways & Electric Company over a year ago, and which terminated in the new and unburned portion of the Pratt Street power house, extended the entire length of the burned district; and were carrying current to the sub-station at 13,000 volts the second day after the fire, without any interruption to service.

Electric Power Distribution in a Sash and Door Mill.

The new mill of the Baltimore Sash & Door Company, Baltimore, Md., is a good example of modern methods, and illustrates the great advance made in machine installation and factory equipment during recent years. The arrangement of apparatus shows careful and

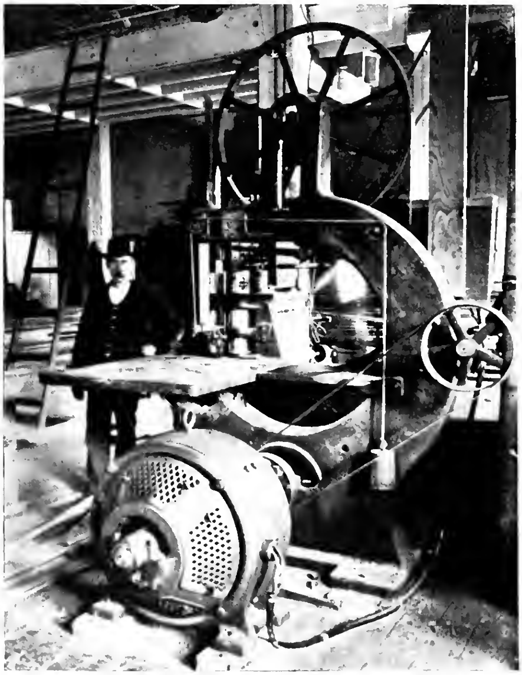

FIG. 1.—BAND SAW.

skillful planning and permits easy handling of material, with a maximum saving of time and labor. No space is wasted, and yet about each machine there is abundant room for operation, together with free head room and a noticeable absence of the intricate belting and shafting usually found in wood-working establishments. Good light abounds everywhere. These obvious advantages are largely due to the foresight of the managers of this company in adopting a system of electric distribution of power, and a well-thought-out plan of motor drive. The plan of driving larger machines each by its own motor, is skillfully combined with group driving for lighter apparatus, the conditions peculiar to the work to be done being the determining factor in this division.

The mill has a present capacity of 500 doors and 600 complete window sashes per day of ten hours, or approximately 150,000 doors and 180,000 sashes in an ordinary working year. A specialty is made of high-grade cypress and white pine.

The main building contains two floors, the first occupied by the door and moulding departments, while the second is largely devoted to the manufacture of sashes. An electrically-operated elevator connects the two and provides adequate facilities for handling the necessary material and machinery.

Exhaust pipes over each machine collect the sawdust and shavings and feed into a storage tank over the boiler house outside the main building. In this way cleanliness is always secured, and fuel, sufficient for the power needed, is delivered to the boilers, practically without handling and at an almost negligible cost. Draught for this purpose is provided by a Sturtevant blower, mounted on a platform under the ceiling of the first floor and driven by a 42-hp Westinghouse open type multipolar motor. The entire system of blower,

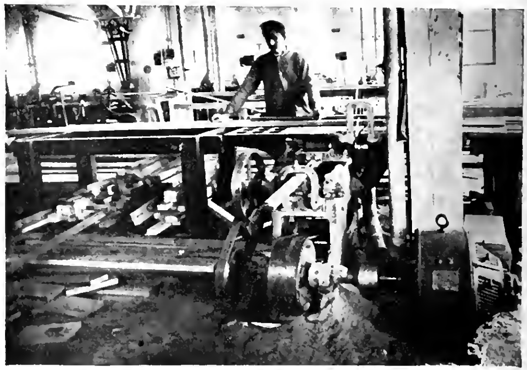

FIG. 2.—CUT-OFF SAW.

piping, storage tank, etc., was installed by the Dixey Blowpipe Company, of Baltimore.

The power plant is located in a separate building. Steam at 80 pounds pressure is developed in a pair of horizontal return tubular boilers, installed by the Thomas Brassher Co., of Baltimore, and equipped with the appliances necessary for burning sawdust fuel. All dust and dirt of fuel are confined within automatic feed pipes leading to the furnace. Boiler and engine room adjoin but are separated by a brick partition.

A 155-hp Ball & Wood simple automatic engine, direct-connected to a 100-kw, 250-volt, direct-current Westinghouse generator is at

FIG. 3.—DRILL STILE BORER.

present in service. A second unit will be added later, as the mill is to be enlarged. A marble switchboard, with all requisite apparatus, furnishes control for the power and lighting circuits, which are run to distributing panels on each floor of the main building. From these distributing centers branch lines run to the various motors and lamps in each department. Means are also provided for the control of each motor at the machine or group of machines which it drives.

Semi-enclosed Westinghouse direct-current "Type S" motors have been adopted as standard, though a few of the multipolar open type are also used. Strong and compact design, high efficiency, large overload capacity and cool operation combine to make this type of motor peculiarly suited to the requirements of machine driving. The

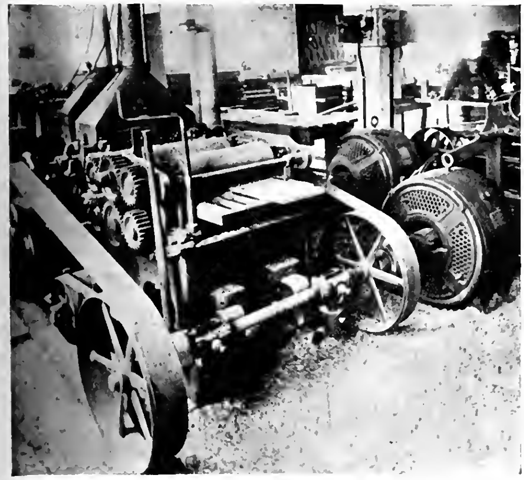

FIG. 4.—MOULDER AND PANEL RAISER.

larger motors are generally compound, the smaller shunt wound. There are, at present, about thirty motors with approximate total capacity of 250 hp. The machine equipment is, in part, as follows:

16-in. cut-off saw, 4,000 ft. per minute, made by J. A. Fay & Co., with 3½-hp, 700-r.p.m. motor. End paneler, made by E. B. Hays Machine Co., with 3½-hp, 700-r.p.m. motor. Panel raiser, capacity 600 panels per day, E. B. Hays Machine Co., with 15-hp, 600-r.p.m.

FIG. 5.—SASH STICKER.

motor. 14-in. moulder, J. A. Fay & Co., with 15-hp, 900-r.p.m. motor. 9-in. moulder, J. A. Fay & Co., with 10-hp, 1,000-r.p.m. motor. No. 4 "American" 40-in. band resaw, with 10-hp, 630-r.p.m. motor. "American" double surfacer, with 7-hp, 900-r.p.m. motor. 42-in. band saw, with 10-hp, 600-r.p.m. motor. 16-in. swing saw, with 3½-hp, 1,600-r.p.m. motor. Vertical shaft variety moulder, 3,000 r.p.m., J. A. Fay & Co., with 2-hp, 1,200-r.p.m. motor. 42-in. sander, J. A. Fay & Co., with 15-hp, 650-r.p.m. motor. Scroll saw, with 2-hp, 1,200-r.p.m. motor. Eight-drill rail borer, E. B. Hays Machine Company, capacity 600 rails per day, with 6-hp, 700-r.p.m. motor. Door clamp, E. B. Hays Machine Co., one door per minute, with 3½-hp, 1,120-r.p.m. motor. Dowel driver, E. B. Hays Machine Co., with 3½-hp, 700-r.p.m. motor. Double-end tenoning machine, E. B. Hays Machine Company, with 16-hp, 1,100-r.p.m. motor. 28-in. drill stile borer, E. B. Hays Machine Co., with 10-hp, 630-r.p.m. motor. This machine will in one day turn out material for 1,200 doors.

On the first floor a 3½-hp motor operates a small group of emery wheels and saw files in the repair shop. In the sash department

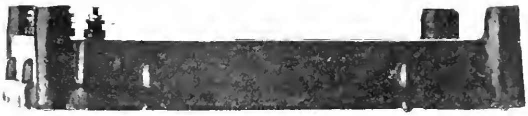
FIG. 6.—SPINDLE RAIL BORER.

10-hp and 15-hp motors, respectively, operate two short line shafts, to one of which are belted two "American" sash stickers, one hollow chisel, one franking machine, one buzz planer and one gang rip saw, while the other drives a six-in., four-sided moulder, one combination saw, one single-end tenoning machine, one "American" sash dovetailer, one chain mortiser, one pony planer, and one emery grinder.

During six months operation the mill has more than met with the expectations of its owners, and has again demonstrated the convenience and economy of motor drive for work of this character. Large orders have already covered the entire output and made an increase in capacity necessary. Additions are being prepared and largely increased facilities provided to meet the growing demand for a well-made product.

Rheostats for Trolley Brakes and Elevators.

The Ward Leonard Electric Company, of Bronxville, N. Y., has devoted some time to the subject of rheostats for use with electrically-operated brakes for trolleys, elevators, etc. Its resistance box for this purpose is constructed with a resistance ribbon in a thoroughly enameled iron box filled with sand, the terminals being brought out. The resistance ribbon or strip is of a special alloy having a practically zero coefficient and is practically of a capacity sufficient to carry overload. Enamel being the best insulator known, protects the rheostat against any possibility of grounding. The sand holds the resistance ribbon firmly in place against any mechanical defects, and as it has a high specific capacity for absorbing heat energy, it will,



RESISTANCE RIBBON.

in the case of excessive overload, absorb the heat energy generated and transmit it to the iron casting, where it will be radiated at a low temperature.

As the box is entirely enclosed in enamel and filled with sand, it is positively protected against the action of the atmosphere, conditions of moisture, etc. These resistance boxes will stand great mechanical stresses, giving out only upon breakage of the casting, but can be readily opened for inspection by removing the cover.

Automatic Motor Starters.

J. L. Schureman & Co., of Chicago, have just incorporated some improvements in their automatic elevator motor starters. One of these is in the dashpot of the single-speed elevator controller, shown in Fig. 1. On this controller, as all who are familiar with the device know, the motor circuit is closed to give forward or reverse motion by a double-throw switch on the top of the rheostat. This switch is operated from the elevator. As soon as the motor circuit is closed, the solenoid mounted on the front of the rheostat, Fig. 1,

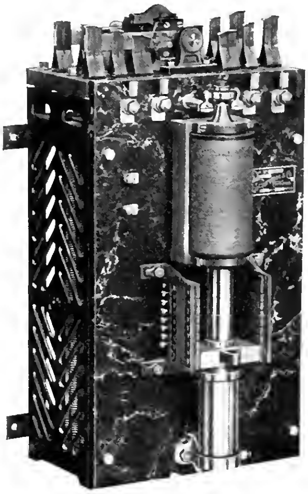


FIG. 1.—RHEOSTAT.

raises the piston slowly, carrying the contacts which gradually short circuit the rheostat. The speed of movement of the piston is determined by the resistance offered by the dashpot. Heretofore an oil dashpot has been used, but in order to get away from any difficulties incidental to the handling of the oil, or the substitution of something else in place of oil by those unacquainted with the device, the company has adopted a vacuum dashpot. The piston working on this dashpot is packed with soft leather, which is held in place by a compressed spiral spring, which forces the leather gently against the walls of the dashpot. The piston in rising creates a vacuum in the lower end of the cylinder. The rate of operation is regulated by a valve in the bottom of the cylinder, which allows the air to flow into

FIGS. 2 AND 3.—AUTOMATIC STARTERS.

the vacuum chamber. On this dashpot a solid iron solenoid core can be used instead of the hollow solenoid core used with the oil dashpot. This permits the plunger to be operated with a smaller amount of energy than on the older type, and the solenoid core does not have to be worked at as high a current density as with the oil dashpot. When the plunger has reached the top of its travel so that the rheostat is short circuited, it can be held in place with much less current flowing in the solenoid core than is required to raise the plunger. Accordingly, a contact is provided just above the solenoid, so that when the plunger reaches the top of its stroke, the contact opens and a high resistance is inserted in series with the solenoid core. This high resistance is short circuited by the contact until the plunger reaches the top of its stroke. Formerly a carbon contact was used for this purpose. This contact has been replaced by small brass contact pieces which are easily renewed and can also be reversed, so as to be worn out on both sides; and the magnetic field created by the solenoid is used to break the arc at this point.

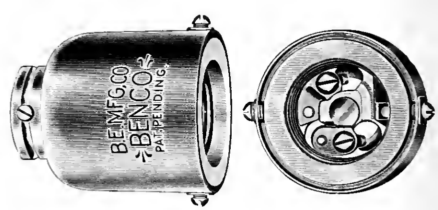
In Fig. 2 is shown an automatic starter for various kinds of stationary motors. This starter can be put to a great number of uses. Where a motor is to be started from a distance with an automatic starter of this kind, it can be done in either of two ways. The circuit to the motor can be closed; in which case the automatic starter will move the rheostat arm around at a proper speed until the motor is up to speed, or if it is desirable not to handle the main circuit, the circuit to the solenoid can be opened or closed to stop and start the motor. Even where it may not be necessary to stop and start a motor from a distance, it may be desirable on account of unskilled labor employed to take the rate of turning on current out of the attendant's hands. This can easily be done with an automatic starter of this kind. One common application of this starter is in connection with electric pumping outfits for maintaining an approximately constant level of water in the tank. In such a case, the gravity float switch, shown in Fig. 4, is operated by the float to open and close the motor circuit. The automatic starter, shown in Fig. 2, does the rest.

FIG. 4.—GRAVITY FLOAT SWITCH.

Fig. 3 is an automatic starter to be used in connection with an air compressor or any other device where the operation of the motor is to be made automatically dependent upon air, water, or steam pressure. The diaphragm valve, shown at the right, Fig. 4, can be set so as to close the circuit through the solenoid of the controller at any predetermined pressure. The motor will then start and continue to operate until the predetermined maximum pressure has been reached, when the diaphragm valve will cause the solenoid to be short circuited, which will allow the rheostat arm to fall back and stop the motor. On this controller the solenoid circuit is closed by the rheostat arm as soon as the motor starts, so that the contact made by the action of the diaphragm valve can be broken at any time after the motor starts. The motor can only be stopped by short circuiting the solenoid. It will be noted that in this pressure regulator, the circuit is never broken by the contacts of the pressure valve, as these contacts only act to close the circuits.

"All-Weather" Socket

The Benjamin Electric Manufacturing Company, of Chicago, is now making a weather-proof socket having a one-piece porcelain receptacle and a one-piece shell of aluminum or brass adapted for



ALL-WEATHER SOCKET.

½-in. or ⅜-in. iron pipe. It is large enough so that wires can be "looped" into it. The binding screws are accessible from the front. It is intended for use in places where exposed to rain or moisture. Two views of one of these sockets are shown herewith, which will give a good idea of the method of construction and the success attained in excluding moisture of any kind.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—Inactivity characterized the stock market dealings although prices were firm at slight improvements, due to a better feeling as to the foreign situation. Another circumstance which influences the market was the continued and increasing ease of money, the accumulation of funds being held to indicate a slackening in trade and a decrease of demands. Decreases in railroad earnings as a result of the abnormally severe winter weather and the generally lighter traffic of many roads is still noted. A little activity was shown in Amalgamated Copper and Brooklyn Rapid Transit. The United States Steel stocks and 5 per cent. bonds were well supported. The electric stocks closed with net gains in all cases, while the net changes in the traction list were all on the negative side. There was uncommon activity in Commercial Cable, the sales of this stock aggregating 1,100 shares, at the uniform price of 191, which was also the closing quotation, representing a net gain of 4 points. General Electric followed next in point of net gain, being in this case, 3 points. Eleven hundred shares were dealt in at prices ranging between 159½ and 162, the closing price being 161. The faith in this stock is gratifying to say the least, in the face of the active preparations for entry into the electrical manufacturing field of another large and well-established concern. Westinghouse closed at the highest figure of the week—161—being a net gain of 2 points. Western Union made a net gain of ½ point, closing at 88. In the traction list, Brooklyn Rapid Transit closed at 39⅞, a net loss of ½ point, and Metropolitan Street Railway, 114, a like loss. The curb market for outside securities showed greater activity for a few issues, although most stocks were dull. Buying of Electric Boat shares was stimulated by the belief in some quarters that the government would order more submarine boats. The common stock closed at 24, and preferred at 55, these being net gains of 4 and 5 points, respectively. Otis Elevator also showed some activity. Following are the closing quotations on the stock exchange, March 8:

TELEGRAPH-TELEPHONE CONSOLIDATION.—According to the *Wall Street Journal,* an authority who has studied the telegraph and telephone situation says: "I see within a surprisingly short period of time a consolidation of the Commercial Cable Postal Telegraph Company and the American Telegraph and Telephone Company, and this is the basis of my calculation: Commercial Cable has just increased its capitalization by practically stock dividends of 300 per cent. T. Jefferson Coolidge, Jr., a director in the Bell, is named as one of the trustees of the new company to take over the Commercial Cable and the Postal. New York parties have recently bought Bell stock in this market. It is through this channel that the Bell people may get a wide market for their securities and a consolidation would lessen construction requirements fully $10,000,000 per annum. It is possible that the new Commercial Cable Company, organized under Massachusetts laws, will be the means of bringing the Bell Company back to Boston. The situation will bear careful watching. In event of a consolidation of the Bell and the Postal, I look for a consolidation of the Western Union and all the independent telephone companies in the United States. Such consolidations all around will save money for every concern interested."

SAN FRANCISCO LIGHTING.—The San Francisco Gas and Electric Company has placed on file its statement of its earnings and disbursements for the year 1903. The revenues amounted to $2,505,212.25, made up of gas sales, $1,445,304.60; electric current sales, $997,407.01; other sources, $62,500.64. The cost of gas was $1,146,873.82, and of electric current $783,381.83, a total of $1,930,-255.65, leaving a net revenue of $574,956.60, from which dividends to the amount of $396,210.83 were paid, leaving at the end of the year a surplus of $178,745.77. It is represented that the original cost of the plant was $9,887,847.33 for gas, and $3,154,731.22 for the electric, a total of $13,042,578.55, and that the present cost of the plant amounts to $25,704,944.84, made up as follows: Gas—Plant, $9,476,-879.05; pipes, $7,075,868.95; meters, $813,651.76; lamps, $77,489.67. Electric—Plant, $6,131,058.56; conduits, $1,933,320.46; meters, $196,-676.39. It is declared that the present value of the plant cannot be determined. The capital stock outstanding is $15,794,284.36; bonds outstanding, $9,813,000; floating debt, $1,091,492.65.

DIVIDENDS.—The Electric Boat Company has declared a quarterly dividend of 2 per cent. on the preferred stock payable April 1. The directors of the Laclede Gas Company have declared the regular semi-annual dividend of 2 per cent. on the common stock, payable March 15. The International Steam Pump Company will close the common books March 21 for the payment of the fourth instalment of 1 per cent. of the 4 per cent. dividend declared on the common stock last June, which is payable April 1. Twin City Rapid Transit directors have declared the regular 1¾ per cent. quarterly dividend on the preferred, payable April 1. Chicago Telephone directors have declared the regular quarterly dividend of 2½ per cent., payable March 31. The directors of the Tri-State Telephone Company (the long-distance lines of the Twin City Telephone Company) have declared the third quarterly dividend, at the rate of 6 per cent. per annum, payable March 1, 1904. Manhattan Elevated has declared the quarterly dividend of 1½ per cent. and 1 per cent. extra, making 7 per cent. for the year. The executive committee of Western Union has recommended the regular quarterly dividend of 1¼ per cent. A dividend of $2 per share has been declared on Philadelphia Traction stock, payable April 1.

COMMERCIAL CABLE REPORT.—At a special meeting of the stockholders of the Commercial Cable Company, held on March 7 the proposed changes in the articles of association and bylaws of the company—providing for eighteen directors instead of fifteen, and that only stockholders can act as directors—were adopted. At the annual meeting, held after the special meeting, the retiring Board of Directors were re-elected. The statement of earnings for the year ended December 31, 1903, showed gross receipts of $11,025,634 and net earnings of $2,508,526. This with the surplus carried over from the previous year amounted to $2,056,055, out of which there were paid interest on bonds amounting to $800,000 and dividends on stock $1,200,000. Of the balance, $350,000 was placed in the reserve fund and $150,000 was added to the fund for the insurance of stations, apparatus, and repair steamer. The balance of income carried down amounts to $156,055. The total reserve fund at the end of the year was $5,372,520, and the insurance fund $1,020,862.

LARGE INDEPENDENT TELEPHONE DEAL.—Advices from San Antonio, Texas, of March 5 say: "E. H. Huntington has closed a deal through Frank C. Smith whereby he becomes owner of thirteen additional independent telephone exchanges in Texas. The new exchanges purchased are the Austin, Taylor, Temple, Belton, Sour Lake, Saratoga, Kountz, Woodville, Village, Kirbyville, Coll, Jasper and Bronson and the long-distance lines of the Commercial and Lone Star Companies. The price paid for these, together with the Houston, Galveston, Corsicana, Nacogdoches, San Marcos, Port Arthur and Liberty exchanges, previously acquired, exceeds $1,000,000.

UNITED STATES TELEPHONE BONDS.—Officials of the Federal Telephone Company are endeavoring to pool the entire issue of United States Telephone Company's bonds at 85 and interest for one year. A committee composed of Calvery Morris, H. R. Newcomb and F. S. Dickson will have power to sell these bonds. The Federal Company owns about $400,000 of these bonds, the Everett-Moore Syndicate $800,000,, outsiders $665,000, while $105,000 remains in the treasury.

Commercial Intelligence.

THE WEEK IN TRADE.—Reports indicate that trade and industry are still irregular, being active in favored sections, but hampered in others by the prolongation of winter weather, with incidental delays in transportation, car shortages and floods. Southern trade advices announce sustained activity; southwestern reports show improvement, and in the West the feeling is optimistic. In the East wholesale and retail trade are backward. There was more activity in iron and steel, and prices of some grades of iron are firmer, but the iron ore situation is yet unsettled. The agricultural situation is, on the whole, one of great strength, and there will be a record-breaking acreage in cotton. The general feeling prevails that settled weather will stimulate and revive general business, and be particularly helpful to building and other lines of out-of-door work, if undisturbed by foolish strikes. Collections are fair to good, and money is exceptionally easy for this season of the year. The features in iron and steel have been the purchase of nearly 100,000 tons by the leading interest, and reports of other sales aggregating as much more. In finished products, reports are more favorable, with mills running to their full capacity. The copper market is dull and uninteresting, and prices are unchanged. Quotations are: Lake 12½ @ 13¾ c.; electrotytic and casting stock 12⅜ @ 12⅝ c. The total exports of copper for February were 16,842 gross tons. *Bradstreet's* reports the number of business failures during the week ending March 3 as 195, as against 200 the previous week, and 171 the corresponding week last year.

LARGE EXPORT TRADE.—Exports of manufactures in January and in the seven months ending with January show a larger total than ever before in the same portions of the year. They amounted to $38,213,352, while the highest January record on any former occasion was that of 1900, when they were $35,586,940. For the seven months ending with January they amount to $250,214,936, and the highest record for that seven months' period in any preceding year was that ending with January, 1901, when the total was $239,564,064. Thus the total for January is two and a half million dollars in excess of any preceding January, and for the seven months ending with January is about eleven millions more than in any preceding seven months ending with January. These figures are shown by an analysis of the January exports just prepared by the Department of Commerce and Labor through its Bureau of Statistics. By far the largest increase occurs in manufactured copper, of which the exports in the seven months ending with January, 1904, are reported at $31,552,677, against $22,514,843 for the corresponding months last year, and $19,038,328 for the corresponding period of the year preceding. Iron and steel stand next in the list of manufactured articles showing an increase in exports. The total value of iron and steel exported in the seven months ending with January, 1904, is $59,125,780, against $55,997,942 in the corresponding months ending with January, 1903, and $57,310,128 in the corresponding months of the preceding year. For January alone the exports of iron and steel are $8,171,738, against $7,437,298 in January, 1903, making the increase for the single month $734,440, and for the seven months about three millions.

THE ELECTRIC STORAGE BATTERY COMPANY, Philadelphia, has recently closed the following contracts for batteries of "Chloride" accumulator for lighting and power. The Union Electric Light and Power Company, St. Louis, Mo., for a battery having a capacity of 462 kw hours in its exciter sub-station. The St. Louis Transit Company will have installed 55 cells of Chloride in its new sub-station for the purpose of operating time switches. The World's Fair Automobile Transit Company have given an order for 100 sets of "Exide" batteries, each set consisting of 44 cells, to be used for the operation of the bus line, which will be in service at the Fair. Isolated lighting and power plants have been contracted for by the Union Trust Building Company, Detroit, Mich.; Morton F. Plant, Groton, Conn.; Bank of Renovo, Renovo, Pa., the the Tucker Electrical Construction Company, for the residence of A. G. Huntington at Bay Chester, N. Y. The Consolidated Railway Electric Light and Equipment Company has contracted for 1020-240 amp.-hour batteries for car lighting. The Herreshoff Manufacturing Company will install on Mr. Herreshoff's private yacht a complete lighting and power battery for operating the search lights, ventilating fans, and electric light throughout the boat. A smaller battery will also be used in connection with an electric launch to be used as a tender for this yacht. The yacht "Marjorie" and the yacht "Roxana" will each have a battery of "Chloride" accumulators installed for lighting purposes.

SOME C & C ORDERS.—The C & C Electric Company, 143 Liberty Street, reports receipt of a number of orders for generators, motors, series parallel equipments, etc. The Aluminum Press Company has ordered a 50-hp, also a 30-hp motor for driving machinery in its Dunellen, N. J., plant. The Greenwood Pottery Company, of Trenton, N. J., has requisitioned additional equipment in the shape of a 20-kw belted generator and a 15-hp motor, also a switchboard, for both light and power purposes. The Boston Navy Yard is to be shipped a 15-hp special motor and special controller for machine tool driving. The Garwood (N. J.) Foundry & Machine Company has ordered a 35-kw belted generator and switchboard for light and crane service. Six motors, varying from 2 hp to 6 hp and of special slow speed type, are to be installed for operating blowers in the University of Pennsylvania Engineering Building, Philadelphia. The Binghamton (N. Y.) *Press* plant is to have a 40-hp series parallel equipment for driving a Hoe printing press. A 20-hp motor, with special control, has been ordered by the Baltimore *Sun*, also to operate a Hoe press. A 75-kw direct-connected generator has been called for by the Miller Lock Company of Frankford, Pa., whose initial generating equipment is of C & C build.

MARCONI WIRELESS.—Communication has been established by the Marconi Wireless Telegraph Company between Broomfield, Essex, England, and Amsterdam, Holland, a distance of 200 miles over sea and 60 miles over land, for commercial wireless service. Arrangements have been made with a Dutch newspaper, the *Handelsblad*, to publish news transmitted daily from England. An agent of the Marconi system has a room in the Stock Exchange at Amsterdam, with private telephone connection with the wireless station, for the purpose of transmitting the daily Stock Exchange quotations to London. The La Gascogne and La Champagne, of the French line, and Grosser Kurfurst, Kaserin Maria Theresa, of the North German Lloyd line, have been equipped with the Marconi system, making the fleet between New York and Europe thus equipped, 38 vessels.

GENEVA ELECTRIC EQUIPMENT AND CONSTRUCTION COMPANY.—A petition in bankruptcy has been filed against the Geneva Electric Equipment and Construction Company, of 469 Fourth Avenue, New York City, by the following creditors: Alfred Gautier, $500; James Steinhauser, $500, and Samuel W. Levine, $150. It is alleged that the company is insolvent, and on February 27 admitted in writing its inability to pay its debts. The business was started in 1894, and the company succeeded to it in May, 1900, when it was incorporated with a capital stock of $10,000. It has never done a large business.

ELECTRIC BOAT ACTIVITY.—The Electric Boat Company is said to have orders for submarine boats the net profits on which will represent several hundred thousand dollars. Already the British Admiralty has bought nineteen boats from the company, and this number, it is stated, is to be increased to twenty-nine boats. A number of the Continental powers have purchased one or more submarine vessels from the company and the United States Government has several in commission.

IMPORTANT MEXICAN ELECTRIC RAILWAY PROJECTED.—It has been decided to construct an electric railway between Morelia, capital of the State of Michoacan, and Guadalajara, the principal city of the State of Palisco, Mexico. The distance between these two places is about 120 miles. Archbishop Silva, of Morelia, is primarily interested in the project. Carlos F. de Sandero, a Morelia engineer, has been commissioned to obtain the usual government concessions.

BALL ENGINE COMPANY, of Erie, Pa., is moving into new works on the western city limits and has its old plant for sale, equipped with power, tools, cranes, shafting, hot air heating system, electric light outfit, etc. It began building engines twenty-one years ago, and has sent them all over the world, particularly for electric light and power purposes. The new plant is unexcelled for capacity and facilities of production.

ELECTRIC TRACTION FOR PACHUCA, MEXICO.—An electric traction system is to be installed in Pachuca, a mining city of some 50,000 inhabitants, located in the State of Hidalgo, Mexico. The Hidalgo Railroad, which connects Mexico City with Pachuca, is completing the purchase of the mule tramways about 12 miles long, and they are to be converted into electric motive power.

STROWGER AUTOMATIC.—Stockholders of the Strowger Automatic Telephone Company at the annual meeting elected J. L. Kesner president, to succeed Elmer Washburne, put in charge by the court after a fight over the annual meeting last year. A. D. Nast succeeded Washburne as director. A. G. Wheeler, Jr., was elected vice-president, J. Siegel treasurer, and M. Sello, secretary.

LIGHTING PLANT FOR MAZATLAN.—The prosperous Mexican seaport town of Mazatlan, located in the State of Sinaloa, is to have an up-to-date Yankee electric lighting plant. Contracts are to be awarded early next month.

CEREAL PLANT TO BE ELECTRICALLY OPERATED.—The Patent Cereals Company of Geneva, N. Y., will shortly install a plant for the purpose of operating its factory electrically. The initial capacity will be about 300 hp.

General News.

THE TELEPHONE.

ABINGTON, ILL.—The Oak Grove Telephone Company has been incorporated with a capital stock of $500. The directors are: T. H. Castle, H. R. Griffith and others.

ANCHOR, ILL.—The Anchor Telephone Company has been incorporated, with a capital stock of $1400, to operate a telephone system. The directors are J. F. Ward and others.

HAZELTON, IND.—The Princeton & Vincennes Independent Telephone Company has been organized here, with C. S. Stevens as president.

INDIANAPOLIS, IND.—The Salmonia Telephone Company has been incorporated with a capital stock of $5000. The directors are: J. J. Kidder, Adam Lee and others.

INDIANAPOLIS, IND.—The Morning Star Telephone Company has been incorporated with a capital stock of $5000. The directors are: Jos. Allen, W. H. Williams and others.

EXIRA, IA.—On March 28 a vote will be taken upon the application of the Marne & Elkhorn Telephone Company, of Rorbeck, Ia., for a local exchange.

PILOT MOUND, IA.—The Pilot Mound Farmers' Mutual Telephone Company, with a capital stock of $10,000, has been incorporated by William Larson, O. W. Hinnan, George O. Durrell, George Owen and L. A. Carlson.

OWENSBORO, KY.—The Stromberg-Carlson Manufacturing Company is installing a 500-line switchboard for the Home Telephone Company. The exchange will connect with an extensive long distance system in this district.

BARBERSVILLE, KY.—The Hayden Telephone Company will build a line between Barbersville and Hayden. An exchange will be established at Manchester, and several toll lines built. John Woodward is general manager of the company.

FALL RIVER, MASS.—The Automatic Telephone Equipment Company has been organized here to operate an automatic telephone exchange and toll line.

BESSEMER, MICH.—The Wisconsin Independent Telephone Company is to extend its lines from Ashland to the Gogebic towns.

EATON RAPIDS, MICH.—The Eaton County Telephone Company is planning to build a line from Charlotte to this city.

CLARISSA, MINN.—A mutual telephone exchange is being promoted here.

EDGERTON, MINN.—The Edgerton Telephone Company has been granted a franchise.

WINONA, MINN.—The Winona Telephone Company will build a 20-mile exchange to Wiscoy.

NEW ULM, MINN.—The Minnesota Central Telephone Company will spend $12,000 on the exchange here.

PELICAN RAPIDS, MINN.—A local telephone company has been organized with a capital stock of $25,000. It proposes to start work in the near future.

STEWART, MINN.—The Electric 'Phone Company has been incorporated with a capital stock of $25,000. Mr. H. E. Posley is one of the incorporators.

LAKE CRYSTAL, MINN.—The Farmers' Telephone Company is the name of a new company just organized here with $25,000 capital. E. Upson is president.

HILLSBORO, MO.—The Festus Telephone Company has been incorporated by F. W. Brickey, W. F. Holt and others.

HARRISONVILLE, MO.—The Cass County Telephone Company, of Harrisonville, has been incorporated, to construct a telephone line, with a capital stock of $50,000. The incorporators are: W. B. Scruggs, R. W. Adams, Duston Adams, W. H. Scruggs and H. B. Moody.

ALBUQUERQUE, N. M.—The Pecos Valley Telephone Company has been incorporated with a capital stock of $50,000. The directors are: J. W. Poe, R. Chaves and others.

DUNDEE, N. Y.—The Dundee, Rock Stream & Reading Center Telephone Company has been organized here.

SYRACUSE, N. Y.—The Syracuse Telephone Company will probably issue bonds for $400,000 for the extension and improvement of its service in this city.

NORTH BOSTON, N. Y.—The Boston Valley Telephone Company has been organized to build a line between Boston and Hamburg. The officers of the company are: President, Fred Frank; vice-president, Philip D. Weber; secretary, Frank X. Weber; treasurer, Edward Heinrich.

BERGHOLTZ, OHIO.—The Bergholtz Telephone Company has increased its capital from $5000 to $20,000.

MANSFIELD, OHIO.—The Central Union Telephone Company will expend $30,000 in improvements on its plant here.

HICKSVILLE, OHIO.—The Hicksville Telephone Company has increased its capital from $25,000 to $40,000, and will make improvements.

WALDO, OHIO.—The Waldo Home Telephone Company has been organized with $25,000 capital stock, and will build a local exchange.

AKRON, OHIO.—The Springfield Township Rural Telephone Company, capital $10,000, has been organized by farmers of Springfield township.

CALDWELL, OHIO.—The Farmers' Independent Telephone Company has been organized here by Judge L. W. Wheeler, H. W. Kuntz and E. W. Spannagel.

KINGSVILLE, OHIO.—The Central Union Telephone Company has installed an exchange at Kingsville and is building a farmers' line throughout a wide district.

MARIETTA, OHIO.—The Marietta Telephone Company has been organized, with A. L. Gracey, president; F. P. Moats, treasurer, and A. C. Davis, secretary and general manager.

MIDDLETOWN, OHIO.—The Middletown Home Telephone Company, capital stock $10,000, has been incorporated by C. H. Osler, F. N. Ramsey, Albert Emanuel, R. E. Kline and H. P. Miller.

AUSTINBURG, OHIO.—The Austinburg Telephone Company has secured right of way from Austinburg to Geneva, and is asking for a franchise in Geneva. G. W. Mooney is at the head of the company.

PERRYSBURG, OHIO.—The Maumee Valley Telephone Company has been organized by Norman L. Harrison and others, with a capital stock of $15,000. Telephone lines will be built through Wood, Henry and Lucas counties.

TIFFIN, OHIO.—The Tiffin Home Telephone Company has increased its capital stock from $60,000 to $125,000. F. B. Myers has been elected president, and J. J. Kintz, secretary and manager. The company is planning improvements.

CHAGRIN FALLS, OHIO.—Fire in the exchange of the Chagrin Falls Telephone Company, a few days ago, damaged the office and practically destroyed the switchboard. The system supplies connection for farmers throughout a wide district.

HAMILTON, OHIO.—The Hamilton Home Telephone Company, the Oxford & Indiana Telephone Company, the Morning Sun Telephone Company and the Darretown Telephone Company have completed arrangements for the free interchange of calls. Towns within a radius of 40 miles will be connected.

STEUBENVILLE, OHIO.—Farmers of this vicinity have organized the Fernwood Telephone Company. John Gault has been elected president, and Joseph Scott, general manager. They have made an arrangement with the Reed's Mills Telephone Company to connect with all the towns in this vicinity. They are in the market for a small switchboard, as well as other material.

CARPENTER, OKLA.—The Elk City Northern Telephone Company has been incorporated with a capital stock of $5000. The directors are: Jos. Moad, D. L. Cliff and others.

MORGANSTOWN, PA.—At the annual meeting of the Conestoga Telephone & Telegraph Company recently held here, the board of directors was organized by the election of the following named officers: President, M. H. Hertzler; vice-president and secretary, Jacob Hartz; treasurer, H. B. Best.

CHARLESTON, S. C.—The extensive system of the Gordon Telephone Company, of Charleston, has been bought out by the Southern Bell Company and the two interests will be merged as soon as possible. The Gordon Company, it is said, desired to sell. The price paid, while small, was sufficient to meet all obligations of the Gordon Company, of which M. C. Duncan will remain in charge.

NASHVILLE, TENN.—The Cumberland Telephone & Telegraph Company is seeking permission to place its wires underground in the business portion of the city.

DENTON, TEX.—The People's Home Telephone Company has just completed the installation of its new exchange at Denton and will begin operations with about 250 telephones in a few days.

AUSTIN, TEX.—The Comptroller of Public Accounts of the State of Texas has taken steps looking to the enforcement of the law requiring all telephone companies operating in that state to pay an annual tax on each telephone instrument in use. It is conservatively estimated that there are fully 250 telephone companies operating in Texas. Of this number only 29 have complied with the law requiring the payment of taxes on the telephones which they had in operation on January 1, 1904.

SALT LAKE CITY, UTAH.—At the recent meeting of the stockholders of the Rocky Mountain Bell Telephone Company a report was submitted showing an increase in business of 25 per cent. over the previous fiscal year. The net gain reported was $215,042.73. The present board of directors was re-elected with the exception of Charles W. Clark, whose place was filled by the selection of Governor B. F. White, of Montana.

WINCHESTER, VA.—The Southern Bell Telephone Company has secured a franchise at Winchester, paying $250 therefor.

MONROE, WIS.—The Monroe Telephone Company has increased its capital stock from $20,000 to $50,000.

GLIDDEN, WIS.—The Glidden Telephone Company has been incorporated with a capital stock of $24,000 by J. R. Whittaker, W. L. Schuppert, E. B. Gordon, David Bodway, J. W. Hoops and George L. McCurdy.

MILWAUKEE, WIS.—It is stated that the Independent Consolidated Telephone Company will establish an exchange in this city within a year. It is calculated that an adequate system will cost over $1,000,000, but the company, it is stated, is prepared to go ahead with the work.

TLANALPAN, MEX.—A telephone line is being constructed from Tlanalpan to the town of Tepeapulpo.

CULIACAN, MEX.—The Government of the State of Sinaloa has granted a concession to Antonio Echevarria to establish a telephone system in the Mocorinto district of the state. All the principal towns and villages in the district will be connected by long distance lines.

MONTREAL, QUE.—At the annual meeting at Montreal on February 25 of the shareholders of the Bell Telephone Company of Canada, the directors were authorized to issue $2,000,000 new stock at $125, in five installments of $25 each. This will bring the capitalization up to $8,000,000. The additional capital is required for line extensions and general additional equipment to keep up with the rapid growth of the country. The annual report of the company shows that 8,691 subscribers have been added to the list during the past year. The total number of instruments now earning rental in the Dominion is 57,172. The company now owns and operates 421 exchanges and 672 agencies. About 4121 miles of wire were added to the long distance system in 1903, and the long distance lines now opened and operated by the company comprise 30,969 miles of wire on 7685 miles of poles.

Electric Light and Power.

EAST LAKE, ALA.—The citizens of East Lake will vote on March 28 on the question of issuing $13,500 bonds for an electric lighting plant.

ANNISTON, ALA.—The Anniston Stove Works Company is to build a $50,000 plant which will be probably operated by electric power, each machine having an independent motor. Mr. O. W. Snyder is manager.

GILROY, CAL.—The Council is considering the establishment of an electric light system.

SEBASTOPOL, CAL.—G. W. Swain has petitioned for a franchise to establish a light and power plant.

SAN FRANCISCO, CAL.—The California Gas & Electric Company on February 29 absorbed the Standard Electric Company and United Gas & Electric Company. The company has more than 1100 miles of line and it sends power to many cities within a radius of 250 miles of San Francisco.

LOS ANGELES, CAL.—The Union Power Company has been incorporated with $2,000,000 capital, $15,000 paid in, to produce electric light, power and heat by the utilization of the waters of the Santa Ana River. The directors are: J. B. Miller J. C. Drake, A. C. Balch, F. Forman and Kaspare Cohn, of Los Angeles, and J. S. Torrance, of Pasadena.

GEORGETOWN, CAL.—Negotiations are reported under way with the American River Electric Company to extend a line from a point near the Delmatia Mine, in the Kelsey district, to Georgetown for power and lighting purposes. The line will be about 9 miles in length. Superintendent Everson, of the El Dorado Copper Mining Company, is at the head of the movement.

WASHINGTON, D. C.—A bill has passed the United States Senate authorizing the Minnesota Power Company to construct a dam across the Mississippi River between Wright and Sherburne Counties, Minnesota.

PENSACOLA, FLA.—Bids are wanted for $50,000 water, light and ice factory bonds. Address P. O. Box 632, Pensacola.

HIGH SPRINGS, FLA.—The Council has under consideration the matter of issuing bonds for water works and an electric light plant.

BERN, IND.—H. H. Stucky has petitioned for a franchise for an electric light plant.

FT. WAYNE, IND.—The Ft. Wayne Electric Light & Power Company is considering plans for a power plant.

SOUTH BEND, IND.—The Oliver Chilled Plow Works, of South Bend, will run its power wires underground from the new power plant to the factory, requiring about 6000 feet of conduit.

INDIANAPOLIS, IND.—The Board of Public Works has awarded the contract to light this city for the next ten years to the Indianapolis Light & Power Company, which was the lowest of the three bidders. The contract price is $75 a year for each light on both direct and alternating-current enclosed arc lamps, and $74 on direct-current open arc lamps. The company also bid $35 a year on 50-cp incandescent lamps. The competitive bids were made by George E. Fisher, of Detroit, and E. C. Bruckman, of New York, who bid $78.50 on arc lamps, $32.50 on incandescent lamps, $83.82 on the alternating-current enclosed arc lamps and $26.25 for the 50-cp incandescent, respectively. The former price paid to the successful company was $85 a year for each light on a moonlight schedule. The new contract is for an all-night schedule.

SAPULPA, I. T.—It is reported that an electric light plant will be constructed here, at a cost of $27,500.

LENOX, IA.—The Town Council has granted a 25-year franchise to S. E. Wainright to construct and operate an electric light plant, to cost about $7000.

ANNAPOLIS, MD.—A bill has been introduced in the State Senate incorporating the Towson Electric Co.

KENSINGTON, MD.—A bill has been introduced in the State Legislature to authorize this city to issue bonds for water works and an electric light plant.

GLADSTONE, MICH.—The Village Council has granted a franchise to local parties for an electric light plant.

GOBLEVILLE, MICH.—The matter of issuing $20,000 bonds for municipal water works and a lighting plant is under consideration.

MERIDIAN, MISS.—The Meridian Light & Power Company will increase its capital stock from $750,000 to $1,000,000.

ABERDEEN, MISS.—The Aberdeen Electric Light & Power Co., of Aberdeen, has been incorporated with a capital of $15,000, by E. M. Jones, J. R. Jones, C. C. Tubbs and others.

ST. LOUIS, MO.—The Laclede Power Company, of St. Louis, has won its fight with the City Water Department on the question of its right to draw its own water from the Mississippi River.

SEDALIA, MO.—It is reported that Mayor Babcock will soon lay before the City Council plans for an electric light plant, and will recommend that it be built, and the contracts at present existing not be renewed.

LIBBY, MONT.—Bids will probably be received in July for an electric light plant, to cost about $6000.

PENN YAN, N. Y.—Horace B. Smith is at work on plans and specifications for a municipal electric light plant.

VICTOR, N. Y.—The Rochester & Eastern Railway Company has submitted a proposition to the Village Board to furnish incandescent lights for both public and private use.

PENFIELD, N. Y.—The business men and citizens are interested in the construction of an electric light system. It is proposed to procure the current from the plant at Lincoln Mills.

LOCKPORT, N. Y.—A resolution has been passed by the Common Council directing an election on the proposition to install a municipal electric light plant, at a cost not to exceed $50,000.

SODUS, N. Y.—Two applications have been made to the Town Board of Trustees for franchises for an electric light plant. One from Omar Curtis, of Wolcott; the other from the Sodus Gas & Electric Light Company, recently formed.

BROOKLYN, N. Y.—Bids will be received until March 14 by C. B. J. Snyder, superintendent of school buildings, New York City, for installing electric light wiring, fixtures and electric bell system in School No. 47, Borough of Brooklyn.

NEW YORK, N. Y.—Bids will be received March 15 at the Bureau of Supplies and Accounts, Navy Department, Washington, D. C., for furnishing the navy yard here a quantity of electric motors, motor-generators, generating sets, conduits and fittings, wire, wiring appliances, incandescent lamps, electric light fixtures, copper pipe, brass fittings, valves, etc. H. T. B. Harris, Paymaster-General, U. S. N.

NEW YORK, N. Y.—Commissioner John T. Oakley, of the Department of Water Supply, Gas and Electricity, has advertised for bids for the city lighting for a year from March 16. This includes the lighting of streets, parks and public buildings by both gas and electricity, and in advertising for contracts dated from March 16 instead of dating back to Jan. 1 the city officials let it be known that they will let the companies continue their fight in the courts for payment for the light supplied in 1903 and up to March 15 of the current year. The lighting appropriation for last year amounted to $3,306,346.

GOLDSBORO, N. C.—It is proposed to increase the capacity of the electric light plant. Address C. Dewey, chairman of the Board of Public Works.

CHARLOTTE, N. C.—W. S. Lee, Jr., of Rock Hill, S. C., vice-president and chief engineer of the Catawba Electric Power Company, of Rock Hill, S. C., writes that it is proposed to construct a sub-station at Charlotte, and to build 18 miles of high potential transmission line.

FARGO, N. D.—The Union Light, Heat & Power Company will improve and enlarge its plant.

DRAYTON, N. D.—John R. Hogg is interested in the construction of an electric lighting plant.

WEST MANSFIELD, OHIO.—Bids are wanted April 1 for $11,000 electric light bonds. C. D. Atkinson is clerk.

BELLEFONTAINE, OHIO.—The Board of Public Works has had plans prepared for a municipal lighting plant to cost $60,000.

CONNEAUT, OHIO.—The city will make some improvements to its electric light plant. Some pumping machinery will also be installed.

WAPAKONETA, OHIO.—The Village Council will issue $7000 worth of 5 per cent. bonds for the purpose of enlarging and improving the village lighting plant.

CARDINGTON, OHIO.—The Cardington Electric Light & Power Company, capital $15,000, has been incorporated by G. M. Schambs, J. W. Glauner, W. P. Vaughan and others.

SALEM, OHIO.—J. S. Kleinfelter, of the proposed Salem Electric Light, Heating & Ice Company, states that a location for the plant has been secured and that the ice and electric lighting plant will be in operation about June 1.

WILKESBARRE, PA.—Mayor Price has signed the bill granting a franchise to the Ashley Electric Light Company. The ordinance granting a franchise to the West Side Electric Light Company has been reconsidered by the Council and passed on final reading.

SOUR LAKE, TEX.—It is reported that another electric light and power plant is to be installed here. D. O. Lively can probably give information.

AMERICAN FORK, UTAH.—The local electric light company will build a line to the pumps on Jordan River. The capacity of the plant is being greatly enlarged.

EAST MILWAUKEE, WIS.—The residents of the scattered village of East Milwaukee are concerned in the move by the Milwaukee Light, Heat & Traction Company to secure a franchise for lighting the village with 18 electric arc lights at $84 per year for each light, the same proposition as was made to West Allis. As East Milwaukee is a country settlement, and there are not a half dozen houses near together in the village, which embraces all of the town of Milwaukee between the lake and the river, and from the northern city limits at Keefe Ave. to the southern limits of Whitefish Bay, some of the residents object to electric lighting as something not needed.

SAN LUIS POTOSI, MEX.—The Governor of the State of San Luis Potosi has called for bids for a municipal electric light and power plant for this city.

MONTEREY, MEX.—The Monterey Electric Light & Power Company has given an order to the General Electric Company for a steam turbine and electrical equipment for the plant in this city.

MONCLOVA, MEX.—The City Council of Monclova has awarded the contract for the installation of an electric light and power plant at this place to Victor M. Braschi & Bro., of the City of Mexico. The plant will cost about $100,000 gold.

PUEBLA, MEX.—The Mexican Government has granted a concession to Archbishop Gillow, of Puebla, for the construction and operation of an electric light and power plant on his Chiautla hacienda, situated in this state. Water power will be used to generate the electrical energy.

KINGSTON, ONT.—Cable advices from London, Eng., announce that the city of Kingston has won before the Imperial Privy Council in the appeal of the Light, Heat & Power Company. This case has been before the courts for over two years. In 1901, the arbitrators fixed the value of the company's plant, which the city is taking over, at the sum of $170,373. They decided that there was no franchise, and left the company to appeal to the courts upon that point. If there could be shown to be a franchise, then the value was fixed at $80,000. The company appealed first to the high courts in Canada, and finally to the Privy Council of Great Britain. All the appeals were decided against the company, and now the city gets the plant at the arbitrators' award of $170,373, less a sum to be fixed for depreciation since 1901.

The Electric Railway.

BESSEMER, ALA.—The Birmingham Railway, Light & Power Company, it is said, will take up the matter planned some time ago, to construct a suburban railway to Jonesboro.

ARKANSAS CITY, ARK.—The contract for the building of the Interurban Railway between this city and Winfield and between this city and the Indian schools at Chilocco, Okla., has been awarded to a St. Louis company. It is expected that the work will cost between $500,000 and $650,000. The power house, general offices, etc., will be in Arkansas City. Mr. L. H. Northrup is the promoter.

SAN FRANCISCO, CAL.—The United Railroads of San Francisco has asked permission to reconstruct as an electric road the steam road which extends from the Cliff House.

LOUISVILLE, KY.—The Louisville Railway Company directors recently re-elected the present officers, as follows: T. J. Minary, president; St. John Boyle, vice-president and general counsel, and Samuel G. Boyle, secretary and treasurer. The annual statement shows nearly $2,000,000 gross earnings. During the past year an underground conduit system has been begun, a large addition to the power house has been made and the construction of the three suburban lines has been pushed as rapidly as possible. Three sub-stations for these lines have been erected. Bonds to the extent of $210,000 were sold.

DULUTH, MINN.—The Duluth Street Railway Company will probably install an air or electric hoist in its new repair and paint shops, as well as a few small machine tools.

ST. PAUL, MINN.—A bill is before Congress granting permission to the Minnesota Power & Trolley Company to construct a dam across the Mississippi River two miles above Elk River, 950 feet long, which it is estimated will develop from 15,000 to 20,000 horse-power. This is to be used primarily for trolley lines, and the surplus for commercial purposes. An interurban and a belt line is contemplated.

MERIDIAN, MISS.—The "Jim Crow" law recently enacted in Mississippi has severely hurt the street railway business in this state. There are but 28 miles of electric railway in the entire state, of which seven are in Meridian. The law compels the street car companies within 90 days either to provide separate cars for the colored people, or to place portable screens in the cars to separate them from the white passengers. The law will have a tendency to stop further street railway extensions and improvements contemplated.

SUMMIT, N. J.—The Cross Steam & Electric Railway Company, which is believed by many to be the successor of the new Orange Railway Company, which about a year ago purchased considerable property through the eastern section of Summit for a railway line and later abandoned the project, has made application to the Summit Common Council for trackage rights in several Summit streets. The company proposes to connect Summit and Elizabeth by a steam railroad. Louis Keller, organizer of the Baltusrol Golf Club, signed the application. In the application it is set forth that all necessary rights of way through private property had been purchased, and should Summit grant the trackage rights asked for the company would agree to begin the work of construction of the line early during the coming summer.

NEW YORK, N. Y.—Proposals will be received by the Cienfuegos, Palmira & Cruces Electric Power & Railway Company, at its office, Havana, Cuba, or at the office of its consulting engineer, C. C. Vermeule, 203 Broadway, New York, until March 15 at noon, for the following material, delivered f. o. b. ship in the harbor of Cienfuegos, Cuba: 4400 tons of steel T-rails, 70 lbs. per yard; 1200 kegs of spikes, 14,100 (0000) electric rail bonds, 105,000 creosoted railroad ties, 4100 trolley poles, 15,000 barrels Portland cement. Specifications for the above material will be furnished at either of the above offices. Proposals will also be received for grading, bridges, culverts, track-laying, etc., for 39 miles of railway between Cienfuegos, Cruces and Cumanayagua; also for constructing a dam, 4000 ft. of tunnel, a flume, and power house on the Rio Hanabanilla, with an auxiliary dam on the Rio Negro, and clearing about 2200 acres of reservoir lands. Plans, specifications and quantities for the above construction work will be furnished by F. W. Bennett, chief engineer, 128 Calle San Carlos, Cienfuegos, and bidders for construction must inspect the location of the work.

CLEVELAND, OHIO.—The holdings in the Cleveland Electric Street Railway Company of the late Marcus A. Hanna are stated to be worth about $2,000,000.

DAYTON, OHIO.—John H. Boroff, representing the Interstate Traction Company, has applied to the Montgomery County Commissioners for a franchise for an electric railway from Dayton to Indianapolis.

COLUMBUS, OHIO.—The Columbus, Buckeye Lake & Newark Traction Company is preparing to make $10,000 worth of improvements at Buckeye Lake, but it has given up the plan of building a new hotel at the resort.

COLUMBUS, OHIO.—The Findlay, Forest & Marion Railway Company, of Columbus, has been incorporated with $10,000 capital stock. Incorporators are: Claude Meaker, W. B. Beebe, H. E. Armbruster and W. B. Earnhart.

MANSFIELD, OHIO.—The Mansfield & Mt. Vernon Traction Company, with a capital stock of $10,000, has been incorporated by Wm. W. Branyan, A. B. Beverstock, Mark H. Arnold, E. R. Rumpler, W. A. Hambleton, Frank Fairchild and C. G. Cooper.

CINCINNATI, OHIO.—The Cincinnati Suburban Belt Line and the Cincinnati, Chester Park & Red Bank Belt Line have practically agreed on terms of consolidation. Thomas P. Egan, of the Fay & Egan Company, has been tendered the presidency of the consolidated company.

DAYTON, OHIO.—The Dayton & Muncie Traction Company has elected these officers: J. E. Lowes, president; A. Newsalt, vice-president; J. E. Feight, secretary; W. B. Gebhart, treasurer. The road is under construction from Greenville, O., to Muncie, Ind., and will probably be completed by August.

YORK, PA.—It is proposed to petition the Maryland & Pennsylvania Railroad Company to change the motive power on its line from steam to electricity.

YORK, PA.—Nearly all the rights of way have been promised for an extension of the York County Traction system from Red Lion to Airville.

HARRISBURG, PA.—The Wilkins & Braddock Electric Street Railway Company has been chartered to build an electric railway 3½ miles long in Allegheny County. The capital stock is $21,000.

HARRISBURG, PA.—The Valley Traction Company has begun work on the enlargement and improvement of the Bridgeport power house. A new boiler house is being built and an extension added to the present plant. When completed the capacity of the plant will be more than doubled. The boiler house will be 100x40 ft., and equipped with five Babcock & Wilcox high-pressure boilers. The extension to the main building will be 30 ft. long.

BLOOMSBURG, PA.—The Danville & Bloomsburg Street Railway Company has given out contracts as follows: For boilers and engines, to the E. Keeler Company, of Williamsport; generators, to the Crocker-Wheeler Company, Ampere, N. J. The power house will be built at Grovania. At a recent meeting of the company further arrangements were made for the early commencement of work on the new 12-mile line. The contract for building the line has been awarded to the Standard Construction Company, of Allentown.

NASHVILLE, TENN.—At the annual meeting of the stockholders of the Nashville Railway & Light Company all of the former officers and members of the board of directors were re-elected.

KNOXVILLE, TENN.—The Knoxville Street Railway & Electric Light Company has been sold to Ford, Bacon & Davis, of New York. It is stated that extensive improvements will be made in the near future.

EL PASO, TEX.—It is announced that interests closely identified with the Union Traction Company, of Indianapolis, Ind., will build an electric interurban railway from El Paso to Las Cruces, New Mex.

TEMPLE, TEX.—The Pennsylvania men who contemplated building an interurban electric railway between this place and Belton have abandoned the project after making a personal investigation of the situation.

SALT LAKE CITY, UTAH.—The Salt Lake & Brigham City Electric Railway Company has been granted a franchise to construct its proposed electric system through Davis County. The road will connect Salt Lake and Ogden. It will eventually be extended from Ogden to the northern boundary of the State.

NORFOLK, VA.—The Norfolk Railway & Light Company and the Norfolk & Atlantic Terminal Company have discontinued their service to Old Point on account of lack of patronage. The schedule to Old Point may be resumed later.

COLFAX, WASH.—A franchise has been granted to the Palouse & Spokane Electric Railway Company by the County Commissioners for the construction of its system from Spokane to this city and from here to Penawawa, in the extreme east of the State. The company has already done considerable grading for the proposed road.

WHEELING, W. VA.—It is stated that the Wheeling Traction Company has awarded Coulter & Furtwangler the contract for the extension of its lines from Pasco to Barton.

HUNTINGTON, W. VA.—The Huntington & Charleston Railroad Company has been chartered with $20,000 capital, to build a steam or electric road between these cities. W. R. Thompson, E. M. Eatts and others, of Huntington, are the incorporators.

WAUPACA, WIS.—The Waupaca Electric Light & Railway Company, which owns and operates a five-mile street and interurban railway and an electric lighting plant at Waupaca, has just held its annual meeting and elected the following officers: President and general manager, Irving P. Lord; vice-president, W. H. Lord; secretary, John D. Caughell; treasurer, P. M. Olfson. These gentlemen, together with J. W. Evans, constitute the board of directors. The total income of the company for 1903 was $18,092.68; operating expenses, including taxes, insurance and maintenance account, $8366.06; interest on bonded indebtedness, $2040; showing net earnings for the year of $7686.62, or a trifle over 10 per cent. on the capital stock of $75,000. The company has increased its capital to $125,000 and intends to make some extensions this spring.

OTTAWA, ONT.—It is announced officially that the Ottawa & New York Railway, operating between Ottawa and Tupper Lake, N. Y., is to be converted into an electric road during the current year.

WATERLOO, ONT.—A company now seeking incorporation asks for permission to build an electric railway from Wellesley, in Waterloo County, via Stratford and St. Marys to Clinton, thence in a southwesterly direction to Bayfield.

OTTAWA, ONT.—The incorporation of a company to build an electric railway from Brantford to Hamilton, Ont., will be sought from the Dominion Parliament at its approaching session. Authority will also be asked to permit the company to convey electrical power over the right of way, and to sell and distribute the same within the municipalities traversed by the line.

OTTAWA, ONT.—According to the official returns of the department of railways and canals for Canada, just issued, giving statistical information for the past fiscal year in respect to railways in Canada, it is shown that the mileage of electric railways in Canada was 759, as against 558 in the previous year. In addition to this there were 32 miles of sidings. The gross earnings of electric railways totalled $7,223,677, as against $6,406,438 for the previous year. The net earnings were $2,760,819. There were also large increases in the number of passengers and freight carried. Last year there were 155,662,812 passengers carried and 371,182 tons of freight moved.

MONTREAL, QUE.—A party of engineers is now locating the route of the new Montreal-Ottawa Electric Railway.

QUEBEC, QUE.—Hon. John Sharples, J. Bell Forsyth, A. C. Dobell and others purpose forming a company with a capital of $100,000, to connect the parishes of St. Colomban, Sillery, Bergerville and Charlesbourg with the city of Quebec by means of an electric railway.

LEGAL.

SWITCHBOARD SUIT.—The Western Electric Company has brought suit against the Rochester Telephone Company, of Rochester, N. Y., based on the allegation that the Rochester Company's switchboard is an infringement on a patent controlled by the Western Electric Company.

WHAT IS A CORPORATE GIFT?—Charles C. Worthington has been sued by the corporation of Henry R. Worthington, of which he was president until November, 1900, for $12,570, the cost of the scientific apparatus which Mr. Worthington in 1897 presented to the School of Mines of Columbia University as a memorial to his father, the founder of the firm. The corporation, with which Mr. Worthington has severed his connection altogether, claims that he ordered the apparatus—consisting of steam pump machinery and various auxiliaries—agreeing to pay for them. Mr. Worthington denies any personal liability for the material and apparatus. He contends that they were presented as a corporate gift, and that the firm is liable for the cost.

HORSE AS A MISSILE.—New York Supreme Court Justice Nash has decided that a street railway company is not necessarily liable if a horse, belonging to somebody else, pokes its head through a car window and injures or frightens any of the passengers. The decision arose out of the suit brought by Christine T. Grant against the Metropolitan Street Railway Company to recover for injuries she sustained in just such an accident about a year ago. She was riding in a Fourth Avenue car, which stopped suddenly at Twenty-third Street. A horse that was crossing Twenty-third Street was going too fast to be stopped in time, and its head crashed through the window where Miss Grant was sitting. She was struck by flying pieces of glass and suffered from shock. She held that the company was necessarily liable, but Justice Nash holds that where, as in this case, the accident is the result of contact with some object over which the company had no control, the legal status is just the same as if Miss Grant had been injured by a flying missile thrown at the car.

CUTTING TREES FOR WIRE STRINGING.—The Supreme Court of Iowa has recently held that the measure of damages for unreasonable cutting of trees for the erection of a telephone line is the difference between the value of the land as it would have been if the cutting had been reasonable and what it was after the cutting, not the difference between the value before and after the cutting. In a case recently before the Supreme Court of Wisconsin, a somewhat similar point was up in regard to the Waukesha Electric Light Company. It appeared that Revised Statutes 1898, sections 925-88, applicable to cities of a certain class, provides that the time "and manner" of using streets for placing electric light poles "shall" be determined by the Board of Public Works, subject to review by the Common Council. An ordinance granted an electric light company the privilege of using the streets, subject to the direction and supervision of the Board of Public Works, in the setting of poles, etc. The board made an order authorizing the use of certain streets, but not designating any particular places where poles should be put. The Supreme Court held that the company had no right to set a pole in front of an abutting owner's property, so as to require the trimming of his shade trees, without his consent.

OBITUARY.

MR. ANDREW HOWARD, president of the Phœnix Glass Company, died Feb. 27 at Wilkinsburg, Pa., of pneumonia, after an illness of ten days. Mr. Howard was born in Pittsburg in 1837, and started life as a clerk with the transportation firm of Clark & Thaw, which afterward was merged in the Star Union Line, Mr. Howard becoming cashier of the latter. He resigned this position in 1880 to organize the Phœnix Glass Company, for the manufacture of a patent glass insulator, which product, however, was abandoned and the manufacture of lamp chimneys taken up. From this beginning, and principally through Mr. Howard's enterprise and energy, the Phœnix Glass Company steadily progressed to its present large proportions. Mr. Howard enjoyed great popularity among his numerous employees, an evidence of which were the lavish floral offerings from these at the funeral.

MR. JOHN S. KING.—Mr. John S. King, treasurer of the David Williams Company, of this city, died on March 4 at his home in Brooklyn. He was born at Middletown, N. Y., in 1841, and learned the trade of a printer there. He went to the front in the civil war as a private in the Eighteenth New York Regiment, and was seriously wounded by one of the last shots fired in the battles before Richmond, immediately before the surrender of that city. He was acting adjutant of his regiment at the time. In 1898 he was made treasurer of the David Williams Company, and continued as business manager of *The Iron Age*, *The Metal Worker* and *Carpentery and Building*. He was also made treasurer and general manager of the Williams Printing Company upon its organization. Mr. King was a member of a great many Masonic organizations and of the Sons of American Revolution, Grand Army of the Republic, Loyal Legion, Society of the Army of the Potomac, Hardware Club and the Union League and Aurora Grata Clubs of Brooklyn. Mr. King is survived by his wife, who was Miss Gertrude Murray, of Hudson, O., and six children. The funeral services were held from his late residence.

MR. J. D. EASTERLIN.—We regret to note the death of Mr. John D. Easterlin, the special agent of the Southern Bell Telephone & Telegraph Company, this sad event taking place at Marietta, Ga., after a short illness, on February 17. His illness began with a slight earache, but his condition rapidly became more serious and he succumbed in a few days to mastoiditis. He was born at Bamberg, S. C., June 21, 1844, and began his electrical career as a telegraph operator, becoming at an early age manager of the office at Charleston, S. C. He was for many years manager for the Southern Bell Telephone & Telegraph Company in the same city and afterwards district superintendent there, as well as at Macon, Ga. In 1890 he went to Atlanta, occupying the same position, but for the last five years larger responsibilities had been put upon him and he had been made special agent to assist the general manager of the company. In this work his long experience, sound judgment, indefatigable industry, and genial manners, secured him success which rounded out his long career of usefulness. His death is greatly felt by his old friends and associates. Mr. Easterlin was deacon in the Jackson Hill Baptist Church of his city, and was also a Royal Arch Mason. He leaves behind him a wife, two sons and one daughter, and two grandchildren. The funeral services were held in Charleston, S. C.

PERSONAL.

FIRST LIEUTENANT F. E. LYMAN, JR., has resigned from the U. S. Signal Corps, to take effect March 25.

MR. LOUIS ALBERGER, of the Alberger Condenser Company, Liberty Street, New York, has returned from a three weeks' trip to Cuba.

MR. JOHN S. LAPP, secretary and treasurer of the Locke Insulator Manufacturing Company, Victor, N. Y., was a recent visitor to New York.

MR. CHARLES E. LAWRENCE has become president of the Charlestown, Mass., Gas & Electric Company, in the place of Mr. J. P. Hunnewell, who has resigned.

MR. A. C. RAHE, of the Smith Storage Battery Company, Binghamton, N. Y., was in New York City recently, accompanied by Col. E. H. Hewins, of Boston.

MR. S. G. McMEEN, the telephone expert, has returned to Chicago after completing the preliminary work of mapping Mexico City for the new underground telephone system.

MR. HENRY M. WATSON, formerly president of the Buffalo Railway Company, has been re-elected president of the Bell Telephone Company of Western New York, with headquarters in Buffalo.

MR. W. K. PALMER, M. E., consulting engineer, Kansas City, Mo., has moved his office in that city to Suite 402, Lyceum Building, where he will give attention to lighting and power plants, etc.

MR. MARIUS LATOUR, the well-known French electrical engineer, is now visiting this country, as to his inventions. This journal has recently published one or two communications from him on the subject of his work.

MR. ROBERT T. E. LOZIER, for some time past so prominently connected with the Bullock Electric Manufacturing Company, in charge of its sales department, has resigned in order to engage in electric motor work on his own account.

MR. J. B. COWEN, of the General Incandescent Arc Light Company, has recently returned from an eight months' business trip to Europe, and has assumed charge of the sales department of the above named company in New York.

MR. T. W. CROWLEY has been appointed superintendent of telegraph of the Delaware & Hudson Railroad Company to succeed Mr. J. W. Burdick, who will henceforth devote his entire attention and time to the duties of general passenger agent.

MR. A. KENNEDY ASHWORTH has resigned as assistant manager of the Underfeed Stoker Company, Chicago, to accept the New England agency of the Buckeye Engine Company, Salem, O., with headquarters in the Hancock Building, Boston, Mass.

MR. H. HINE, formerly of the Stanley interests and now president of the Guanajuato Power & Electric Company, which is to considerably extend its operations in Mexico, has left New York for Colorado Springs. He expects to return in about a fortnight.

MR. WALTER ABBOT, one of the directors of the London United Tramways, now controlled by the Underground Electric Railways Company of London, Ltd., of which Charles T. Yerkes is chairman, is now on a visit to this side. He is at present in Boston.

MR. A. J. WURTS, manager and engineer of the Nernst Lamp Company, has been seriously ill for some time past at Pittsburg, and had to go to Atlantic City to recover his strength. We are glad to report that he has now returned to work and has entirely recovered.

MR. W. W. KER, of the Hebrew Technical Institute, is delivering for the New York Board of Education at the Alfred Corning Clark Neighborhood House, another course of free lectures, beginning March 1, devoted to the principles and practice of electrical engineering. There will be eight of the lectures.

MR. WILLIAM T. BENALLACK, of Detroit, Mich., is delivering a course of lectures before the Indiana underwriters' and electrical contractors on "Faulty Wiring." The speaker is president of the National Electrical Inspectors' Association, as well as the head of the electrical inspection of the Michigan Board of Fire Underwriters.

MR. GEORGE WESTINGHOUSE is the theme of a most interesting and very ably written article in the New York *Times* of March 5, by Mr. Arthur Warren, who has studied his subject at close quarters, and has all the qualities needed by a biographer. It is a fine revelation of a great and fascinating personality—of a really great American.

MESSRS. G. C. HENRY and WALTER CASTANEDO, of Atlanta, Ga., who represent the southern interests of the Bullock Electric Manufacturing Company and the Harrisburg Foundry & Machine Works, respectively, are now in New York with a view to closing contracts for the equipment of a 900-hp lighting and railway plant to be built in Florida.

MR. C. P. BRUCH, assistant secretary and assistant general manager of the Postal Telegraph-Cable Company, has received recently a fine gavel as chairman of the conference of officials of that company, from his colleagues, members of the conference. The woods are varied and choice, including a handle made very appropriately from an olive branch.

DR. MAX VON RECKLINGHAUSEN, who has been associated with Nernst and Cooper Hewitt lamp development in this country, has gone to Europe to establish a Cooper Hewitt factory there, so as to meet the demand which has already been created for the lamp. It is hoped that at no distant date the Doctor will return to a country where he has made so many friends.

MR. L. D. GARDNER, recently of the New York *Sun*, and an active member of the Technology Club of New York, has organized the L. D. Gardner Company at 521 Temple Court, this city, to build up a business in radium specialties of all kinds. He has lately been giving attention to the matter, and is the coiner of the phrase "liquid sunshine," as applied to fluorescent liquids, which has so caught the public fancy.

MESSRS. GEORGE BULLOCK, president, and Joseph S. Neave, vice-president, of the Bullock Electric Manufacturing Company, of Cincinnati, are now in New York. They came east primarily for the purpose of attending the special meeting of the stockholders of the company, which will meet in Jersey City, March 16, to ratify the Allis-Chalmers-Bullock deal, to which reference is made elsewhere in this issue. They are guests at the Gregorian Hotel, West 35th Street.

MR. RICHARD E. SACK, formerly of the editorial staff of the ELECTRICAL WORLD AND ENGINEER at the Chicago office, has recently accepted the position of contract agent for the Albert Lea Light & Power Company, Albert Lea, Minn. Mr. Sack will devote his energies to building up the business of this company, especially in the direction of increasing the number of electric motors in use, and securing customers for the new gas plant which the company is just starting. His engineering training and ability should stand him in good stead.

SIR WEETMAN D. PEARSON, Bart., M. P., chairman of the British contracting firm of S. Pearson & Company, Limited, which is undertaking some huge contracts in Mexico entailing the purchase of considerable electrical equipment in the United States, is now in New York en route for England. He is president of the Ferrocarriles de Veracruz, Limitada, which operates some 12 miles of horse tramways in Vera Cruz, Mex. These lines are to be converted to electricity and extended. Sir Weetman is a guest at the Waldorf-Astoria. He expects to remain here for about a week.

MR. P. FARNSWORTH.—Mr. Philip Farnsworth, formerly of New Haven, Conn., has removed to 150 Nassau Street, New York City, where he will continue the practice of general patent law. He has been retained as counsel in several important patent suits. He has had an unusually valuable experience in the practice of patent law, having been associated for several years with Mr. F. H. Betts. Previously, Mr. Farnsworth acted for several years as local counsel at Schenectady for the General Electric Company. He graduated from the Sheffield Scientific School in 1894, and from the Yale Law School in 1897, after which he practiced in Washington, D. C.

MR. HARRY D. PARSONS, who has been superintendent of construction and electrician for the Meridian, Miss., Light & Railway Company, has resigned from that company to accept a position of salesman for the Commercial Electrical Supply Company, of St. Louis, Mo. It may be recalled that Mr. Parsons about five years ago figured in newspaper accounts as the victim of an accident from a 10,000-volt transmission circuit in Texas, being so badly burned that he had to undergo the operation of having almost 300 square inches of flesh grafted upon his body from other people's bodies. The medical journals at that time stated that this was the most successful piece of skin grafting ever accomplished.

MR. W. G. LEVISON.—The March meeting of the New York Mineralogical Club will be held on Wednesday, March 16, 1904, at the residence of Mr. Wallace Goold Levison, 1435 Pacific Street, corner of Brooklyn Avenue, Borough of Brooklyn. The following will speak: Dr. George F. Kunz—"Further observations on substances that respond by phosphorescence to natural radioactive substances," with exhibition of "Actinium"; Mr. George L. English—"Exhibition and description of some twin calcite crystals from a new find at Joplin, Mo." Mr. Levison will exhibit a series of specimens of fluorescent Willemite from Franklin, N. J.; radioactive pitch blende from Bedford, N. Y., and minerals from New York City and other selections from his collection.

MR. B. A. BEHREND, chief engineer of the Bullock Electric Manufacturing Company, is visiting New York this week. In the recent combination of the Allis-Chalmers and Bullock interests, Vice-President W. J. Chalmers has retained and secured the services of Mr. B. A. Behrend as chief electrical engineer. Mr. Behrend's successful work during the past four years in the design of some two hundred thousand kilowatts of large alternating and direct-current machines, has established the engineering reputation of the Bullock Company as a factor in the building of electric power plants of the largest size. Among the more notable designs of Mr. Behrend are the municipal plant at Nashville, Tenn.; 5000 kw of alternating-current generators in Denver, Col.; five 5000-kw generators for the Kern River Power Company, California; the generators for the Pacific Electric Railway Company, Los Angeles; the generators for the Mutual Electric Company, San Francisco; the frequency changers in Montreal, representing 10,000 kw, and numerous other plants of note and interest. The 3500-kw generating unit which will be exhibited by the Allis-Chalmers and Bullock companies at the World's Fair at St. Louis, the largest power unit at the Exposition, was also designed by Mr. Behrend, whose work has also found recognition outside his immediate sphere of activity. Only 29 years of age, he is a full member of the Institute, a member of the Committee of Standardization, chairman of the Cincinnati Branch of the Institute, a fellow of the American Association for the Advancement of Science, and a member of the Advisory Committee, appointed by President Francis, of the International Electrical Congress. Mr. Behrend's treatise on "The Induction Motor" has been translated into French and German, and he has lectured at the universities of Wisconsin, McGill and Leland Stanford.

Trade Notes.

EXHAUST HEADS.—A large plate glass factory at Alexandria, Ind., has placed an order with the Burt Manufacturing Company, Akron, O., for three 16-inch exhaust heads.

MICA INSULATOR COMPANY, Chicago and New York, has issued recently its 1904 price list of micanite, linotape, Empire cloths and papers, "M. I. C." compound, etc. The list goes into details of parts for a wide range of well-known apparatus.

THE ELYRIA ENGINE COMPANY, Elyria, Ohio, has purchased a site in that city and will erect a new plant to cost $100,000. The main building will be 75x175 feet. The company manufactures gas engines. Heman Ely, of Elyria, is at the head of the company.

STROMBERG-CARLSON TELEPHONE MANUFACTURING COMPANY has issued a tasteful and striking folder as to its dry core lead-covered telephone cables, which it makes exclusively for independent telephone companies, in addition to its other wires, cords, cables, etc.

NEW THINGS.—The "New Discoveries in Electricity" which have opened before men new vistas of human possibilities, are described in an 8-page article in *The Living Age* for Feb. 27, with such clearness that even the unscientific reader will find no difficulty in appreciating them.

AL-LECTRO.—The L. B. Allen Company, Inc., Chicago, is handling Allectro, which is a polish for gold, silver, nickel, brass, copper, aluminum, cut glass, etc. It is used by the leading railways, automobile makers, power stations, etc., and is said to be very satisfactory in its results.

WHITEHEAD MACHINERY COMPANY has opened an office at 517 Park Building, Pittsburg, to care for its increasing eastern business. It will be in charge of Mr. Harry G. Adams, formerly with Wickes Bros., of Saginaw, who is thoroughly familiar with the second-hand machinery trade.

THE NATIONAL WIRE CORPORATION, New Haven, Conn., has issued a condensed catalogue of its products, with price lists, tables of wire, etc. This booklet contains a number of valuable tables and a lot of useful information about the wire business. Copies will be furnished free of charge to anyone interested.

THE CHICAGO FUSE WIRE & MANUFACTURING COMPANY reports that it is meeting with great success in the introduction of the "Union" line of outlet boxes for rectangular push button switches of different makes. These boxes are designed primarily for use in finished buildings, or what is known as "old work," and for this purpose they afford great economy, as a hole may be cut and the box inserted without breaking the plaster or woodwork any more than will be covered by the ordinary switch plate. These boxes are carried in stock at the company's stores in Chicago, New York and Buffalo.

GOLD CAR HEATING & LIGHTING COMPANY has moved its offices to the Whitehall Building, 17 Battery Place, New York City, in order to secure more room, so badly necessitated by the remarkable growth of its business in electric and other car heating and in car lighting. The Gold Company has moved its Chicago offices and concentrated them with the New York ones at the new address. The company has also made another important move by securing a contract from Mr. T. A. Edison, under which it has the exclusive sale in the United States of the Edison storage battery for train lighting purposes.

"THINKABLE THINKLETS" is the title of an interesting pamphlet just issued by the Warren Electric Manufacturing Company, Sandusky, Ohio. As the name implies, the contents give some things to think about concerning the Warren alternator, which is so well known. This machine is of the induction type, and its simplicity of construction is well brought out in this unique folder. A list is given of the users of this make of machine, and it is a very long one. The machine is thoroughly illustrated, each of the principal parts being shown up with much clearness. These "thinkable thinklets" should be well thought over by those interested in this line of apparatus, as much can be learned from them.

PHOENIX ENGINES.—One of the most artistically designed catalogues we have ever seen has come to us from the Phoenix Iron Works Company, Meadville, Pa., and while it is artistically and mechanically a model, practical value and utility have not been sacrificed. Utilitarianism and art can be combined in a catalogue as well as anything else requiring expert knowledge and experience in its production. So much for the artistic features of the catalogue. The business side has received as much care. The contents represent the latest and highest development of the Phoenix engine, which is so well known in electric power transmission and lighting enterprises. These engines are built in the simple, tandem-compound and cross-compound types, and are designed to withstand the most exacting service in the generation of electric energy. Each class is illustrated by a typical engine, and it is in the illustrations where the greater part of the artistic skill has been applied. Equally excellent illustrations give views of the most important details of the engines, and cross-section views show in an exceedingly clear manner the internal construction of the cylinders and the assembling and relation of the parts. These illustrations, besides being of great utility to the business man, have educational advantages in that the design and construction of the machines are so clearly displayed. In other words, they give a clear and true conception of the actual mechanism of the steam engine. The text explains briefly the constructional features of these well-known machines, and after a careful study of the contents of the catalogue one is left with a very good idea of the merits of these engines. There are three pages giving reproductions of indicator cars intended to illustrate the advantages resulting from the use of the Phoenix compound valve gear. Views are also given of direct-connected units, the catalogue closing with a set of tables showing dimensions, power ratings, etc., of the various classes of engines under consideration.

ACTON ENGINE ROOM SPECIALTIES.—John Acton, who is one of the well-known manufacturers of engine room and other specialties, has a 32-page catalogue, fully illustrated, giving details of a number of things he makes. Mr. Acton says he has now on his books orders for 12 months ahead. The factory at 118 John St., Brooklyn, N. Y., is running steadily, and the merit of his apparatus has caused him to be flooded with orders.

OTTO WEISS MACHINE DEPARTMENT of the Chase Machine Company, of Cleveland, Ohio, writes as follows through Mr. Thomas A. Aiton, manager: "We manufacture machinery used for forming electric wires and cables and for insulating the same. We manufacture a large range of these machines for all kinds of insulation from silk to lead. I worked from some four years in Berlin, Germany, as assistant to Mr. Otto Weiss, who was for many years the head engineer at Siemens Bros., London, and who manufactured and laid a great number of submarine cables. Later he established his own company in Berlin, for the manufacture of machines used in this line of work. Perhaps it would interest you to know that I have just placed a 4-head cabling machine with the Waclark Wire Company, at Bay Way, N. J. This machine is 96 feet long and weighs 55,000 pounds, and is used for making 61-wire strands up to two million circular mills. We have also placed several of these machines, as likewise similar ones, though smaller, in many of the wire and cable works of this country."

THE STERLING ELECTRIC COMPANY, Lafayette, Ind., reports an unusual business in its solid back long distance transmitters for toll lines, magneto exchanges and common battery exchanges.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED MARCH 1, 1904.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., New York.]

753,252. TELEPHONE-REPEATER; Merritt Gally, Brooklyn, N. Y. App. filed March 18, 1903. (See page 525.)

753,258. ELECTRIC SWITCH; Gerald W. Hart, Hartford, Conn. App. filed Nov. 23, 1903. Means for insulating and mounting the current-carrying parts.

753,276. LAMP SOCKET AND PLUG; Daniel A. Kimbark, Chicago, Ill. App. filed May 21, 1902. A socket and plug designed especially for use on berth-lights; the invention being in the details of construction.

753,278. WINDING FOR ELECTRICAL MACHINES; Frederick J. Lindeman, Pittsburg, Pa. App. filed April 11, 1903. (See Current News and Notes.)

753,321. LAMP SOCKET; Duny A. Schutt, Peru, Ind. App. filed April 7, 1903. A holding device for the two-part cover consisting of a cross-bar embedded in the porcelain to which the shell and cap are secured.

753,345. AUTOMATIC RELEASING DEVICE FOR SAFETY TROLLEYS; Andrew C. Wolfe, Pittsburg, Pa. App. filed July 6, 1903. Details of construction.

753,356. BRUSH HOLDER; Charles O. Bulock, Milwaukee, Wis. App. filed Aug. 21, 1903. A coil-spring supplying the pressure upon the brush is adjustable in tension by engaging any one of its turns with a projection adapted to pass between them.

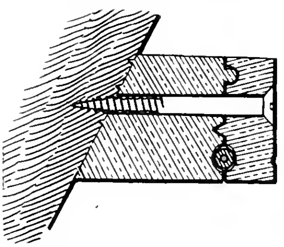
753,365. ELECTROMAGNETIC SIGNAL; William U. Colthar, Springfield, O. App. filed July 24, 1903. The semaphore is moved by causing a cylindrical armature to roll along a track, its rotary motion serving to raise or lower the signal.

753,383. PROCESS OF PREPARING ELECTRODES FOR STORAGE-BATTERY CELLS; Oskar Frank, Detroit, Mich. App. filed May 2, 1903. (See page 526.)

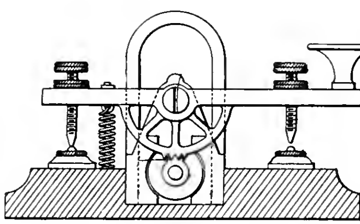
753,391. CASING FOR TELEPHONES OR MICROPHONES; Paul Hardengen, Berlin, Germany. App. filed Sept. 3, 1902. (See page 525.)

753,398. CLEAT FOR ELECTRIC WIRING; Emory C. Hunt, Belle Plaine, Ia. App. filed Nov. 8, 1902. An insulator having an inclined base for attachment to the wall.

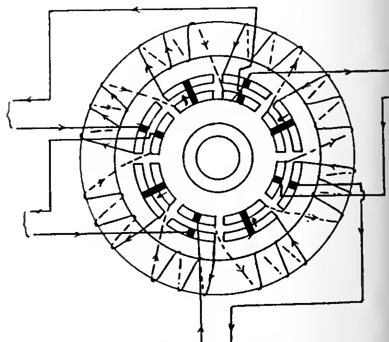
753,399. COMBINATION BRACKET AND KNOB FOR ELECTRIC CONDUCTORS; Emory C. Hunt, Belle Plaine, Ia. App. filed Nov. 8, 1902. An insulator knob is formed integrally with a bracket through which the supporting screw passes.



753,398.—Cleat for Electric Wiring.



753,429.—Electrodynamic Generator.



753,690.—Electric Telegraph Apparatus.

753,422. ARMATURE-WINDING; James F. McElroy, Albany, N. Y. App. filed Nov. 11, 1902. (See Current News and Notes.)

753,429. ELECTRODYNAMIC GENERATOR; George M. Pelton, Chagrin Falls, O. App. filed Sept. 29, 1902. The machine has two sets of commutator segments, each corresponding in number to the number of armature coils; the brushes engaging the commutators are so related that all of the coils may be connected in series or any number in parallel, or two independent circuits may be supplied therefrom.

753,434. RAIL JOINT; Benton C. Rowell, Chicago, Ill. App. filed April 9, 1903. Details.

753,461. ELECTRICAL CONDUCTOR AND COIL; James C. Anderson, Jersey City, N. J. App. filed April 30, 1903. The conductor is a ribbon wire covered with a straight envelope of paper, the edges of which are separated on one side of the ribbon; the turns of the coil are wound with the open side of the covering outward, so that the tension alone will retain the insulation in place in the completed coil.

753,466. DISINFECTING ATTACHMENT FOR TELEPHONES; Carlo Bravi-Bertini, Amboy, N. J. App. filed Sept. 16, 1903. (See page 525.)

753,493. TELEPHONE; Stephen C. Houghton, San Francisco, Cal. App. filed April 3, 1903. (See page 525.)

753,509. ELECTROTHERAPEUTIC DEVICE; Charles K. Munns, Corning, Ia. App. filed Oct. 24, 1903. A cabinet containing devices for generating currents for electrotherapeutic purposes, with switchboard and auxiliaries.

753,533. RHEOSTAT; John C. Barclay, New York, N. Y. App. filed Sept. 9, 1903. (See Current News and Notes.)

753,536. CONTACT DEVICE FOR ELECTRICALLY PROPELLED RAILWAYS; Henri Berthoud, Neuchatel, Switzerland. App. filed July 10, 1902. Each car carries on its roof a contact strip running the full length which overlaps the strip on the adjacent cars, the electrical terminals suspended above drag upon these conductors to deliver current to the vehicle.

753,542. TROLLEY; Alexander C. Calderwood, Gloversville, N. Y. App. filed Aug. 6, 1903. The trolley replacer is tripped and allowed to move into operative position when the wheel leaves the wire.

753,552. TROLLEY FOR ELECTRIC CARS; William A. Daggett, Vineland, N. J. App. filed Sept. 3, 1903. Details.

753,554. TROLLEY; Arthur S. Deem, Reading, Pa. App. filed Aug. 8, 1903. Two trolley wheels, one arranged behind the other and one being pivoted on a horizontal axis while the other is pivoted on a vertical axis.

753,556. ELECTRIC METER; Thomas Duncan, Lafayette, Ind. App. filed Dec. 29, 1903. The object is to provide a construction whereby parts of the rotating elements may be made saparable to enable the substitution of new parts without sending the meter to the factory.

753,562. JACK-FIELD FOR TELEPHONES; Lars Magnus Ericsson, Stockholm, Sweden. App. filed June 18, 1902. (See page 525.)

753,563. PORTABLE OR TABLE TELEPHONE INSTRUMENT; Lars Magnus Ericsson, Stockholm, Sweden. App. filed Sept. 30, 1902. (See page 525.)

753,582. LIGHTNING ARRESTER; Harold N. Keifer, Topeka, Kan. App. filed June 30, 1903. A part of the circuit is wound in grooves on an insulating cylinder, and a flat plate is held against the face of the cylinder within striking distance of the turns thereon, the plate being grounded.

753,595. INSULATED PIPE JOINT; Waldo A. Learned, Watertown, Mass. App. filed Sept. 8, 1903. Details.

753,617. TROLLEY REPLACER; Francis A. Nolan, St. Paul, Minn. App. filed Jan. 16, 1902. Details.

753,666. RAILWAY SIGNAL; Tony Bruck, New York, N. Y. App. filed Jan. 26, 1903. The moving cars strike cam-shaped levers pivoted in the road bed to control the circuits of the signaling system.

753,690. ELECTRIC TELEGRAPH APPARATUS; Agacio Falcone, Florence, Italy. App. filed May 6, 1903. A Morse transmitting key oscillates the armature of a magneto, which at each movement sends an impulse to line.

753,704. AUTOMATIC MAGNETIC CIRCUIT BREAKER; Frank O. Hartman, Mansfield, O. App. filed April 10, 1902. Details of an oil-switch.

753,714. CONDUIT FOR ELECTRICAL CONDUCTORS; Hubert Krantz, New York, N. Y. App. filed Sept. 9, 1903. A metallic conduit having sides terminating in inwardly turned shelves, forming a constricted opening through which the wire may be temporarily passed and held by the shelves until a cover is applied.

753,716. CARBON RESISTANCE AND METHOD OF PRODUCING AND ADJUSTING SAME; George I. Leonard, Pasadena, Cal. App. filed Feb. 3, 1903. (See page 526.)

753,757. SELF-WINDING ELECTRIC CLOCK; Frank T. Talcott and Benjamin F. Kerr, Ashtabula, O. App. filed March 11, 1903. Details of a clock in which the pendulum is actuated by the attraction and repulsion of electro-magnets.

753,759. ELECTRICAL CONNECTION; Edward G. Thomas, Cambridge, Mass. App. filed July 15, 1902. For soldering terminals of rail-bonds to the under face of the rail, said terminals have spout-shaped extensions into which the melted solder is poured and by which it is conveyed to the abutting surfaces of the bond and rail.

753,809. AUTOMATIC PLAYING APPARATUS FOR MUSICAL INSTRUMENTS; Timothy B. Powers and Major R. Jewell, New York, N. Y. App. filed Aug. 14, 1901. Various devices for controlling the resistances in circuit with the magnets which operate the keys so that all the variations and combinations of tone, expression, etc., indicated by a composer can be obtained.

753,819. ELECTRODE; George Jones Atkins, Tottenham, England. App. filed April 8, 1903. (See page 526.)

CONTENTS.

A GREAT TRUST FOR ENGINEERING.

It is with unmitigated pleasure that we announce this week the news that carrying out and broadening plans to which he first gave publicity about a year ago, Mr. Andrew Carnegie has now taken the final steps to create a great trust for engineering in the hands of the three national engineering societies—the American Institute of Electrical Engineers, the American Society of Mechanical Engineers and the American Institute of Mining Engineers. Our readers will remember that at the outset Mr. Carnegie proposed to give $1,000,000 for the erection of a Union Engineering Building in New York City. Matters have now so shaped themselves that the original plans have necessarily undergone extension, so that the three societies find themselves trustees under Mr. Carnegie's gift of a sum of $1,500,000, to be administered by them for the promotion and benefit of engineering work in America. The Engineers' Club, which is rapidly becoming a widespread national body as to membership, is also, as originally intended by Mr. Carnegie, a beneficiary as to its own home, while the Union Engineering Building will now be able to subserve the wants and necessities of a large number of technical engineering societies which have hitherto had neither resting place nor meeting place. A total expenditure of about $2,500,000 is involved in the present plans.

We ventured to predict a few weeks ago that this would be the outcome of the complications of the past twelve months, and were satisfied that as on other occasions of great moment, Mr. Carnegie would rise to the emergency and deal with it in all its broadness of opportunity and obligation. He has, indeed, done a great and noble thing for engineering, one whose merits and benefits will grow as the years run by, and yet something which has been so sorely needed during the past twenty-five years that it is wonderful that no man with the means and the spirit had previously been equal to the occasion. Not only is a great engineering center thus created at the very heart of the Western metropolis, but Mr. Carnegie at once enables a large number of technical societies with a membership of perhaps not less than 15,000 to exercise their functions on the highest scale of efficiency. With each society sharing a common roof, and while the three trustee societies assume notable burdens in providing the land for the building, it is easy to see at once that many new ideas and benefits previously undreamed of must fructify. The national engineering societies, while maintaining their autonomy strictly, will find that co-operation enables them to address themselves more strictly to the needs of their members and the welfare of the public than was possible with each society dwelling in narrow quarters of its own or occupying rented rooms in some small house or office building utterly inappropriate for the purpose.

We believe that there is wisdom, enthusiasm and courage enough in the three national societies, thus so generously endowed by Mr. Carnegie, to execute this scheme on the best possible basis; and we trust that every engineer in the country, whatever his branch of work, will feel it his duty to rally to their aid and support. We consider it also a matter of happy augury that in this new engineering center, and adjacent to the great Union Engineering Building, will be found the Engineers' Club; for the social aspects of the professions are in many respects of equal importance with the technical, and the club now has a mandate which should stimulate it to the very fullest achievement of all the possibilities which lie in these practical conditions. Hereafter from whatever part of the country or from whatever region abroad the engineer may come, he will feel drawn by every claim and association to the center now called into being. So far as the American Institute of Electrical Engineers is concerned, its members have from the first shown themselves enthusiastic over the project, and it is now their duty, as it will undoubtedly be their pride, to co-operate heartily with Mr. Carnegie in doing their share, which is not a small one, to secure the early consummation of the work in hand.

Invention vs. Current Engineering Development.

One of the most difficult matters with which patent courts have had to contend has been a determination as to what constitutes invention, and particularly as to what constitutes an invention as differentiated from a natural development occurring in the ordinary course of the evolution of an art. The fundamental principle applying, as laid down in an opinion by the United States Supreme Court, is that an invention must be the product of some exercise of the inventive faculty. Lacking a definition of what constitutes inventive faculty and a distinction between the inventive and ordinary constructive faculties, this dictum is of the kind that darkens rather than illuminates counsel. The courts being thus without direct guidance, and the determination of what constitutes invention being one of opinion rather than the result of a weighing of evidence, the natural consequence is a great and growing diversity of precedent on the subject. Naturally, the patent office is governed by precedents established by courts having patent jurisdiction, and is further circumscribed by a body of rulings laid down by past and present officials of the office. The net result appears to be that the criterion as to real inventive merit is so difficult to apply that any application for a patent covering anything new, provided that the alleged invention stands test with respect to priority and is not palpably a mere construction or obviously the result of ordinary mechanical skill, will receive favorable consideration and a patent duly issue. There are other and even more flagrant diversions of the intent in establishing the patent monopoly, arising through the grant of patents on what may be called "speculative" inventions, designed to cover future developments in an art, several notable instances of which have worked much harm in the electrical field. Of this class, however, it is not our intention to speak at present.

The great evil of the present looseness in the grant of patents is that undue advantage accrues to those who are in close contact with manufacturing operations and agents in the evolution of new types or in passing from smaller to larger constructions as changes are demanded by an industry. In such cases changes from current practice are usually definitely fixed by the conditions of each particular case, yet we venture to say that in the vast majority of instances, and even when change or improvement is not obvious to the mere onlooker, these conditions indicate what it shall be. In other words, the one who, through the Patent Office, profits by the opportunity, is apt to be merely a fortuitous factor in a situation brought about by the trend of progress, and the work he accomplishes could as well have been achieved by any one of his fellows. Were it not for the statutory monopoly of the fruits of such a situation which inures to the agent, there would be no cause for complaint, since the natural benefit of an opportunity cannot be denied to the one who grasps it. But the grant of patents on engineering improvements as they are in natural course indicated, is an injustice to those manufacturers whose line of work may later enter the field thus covered, and a still greater injustice to the public, which is made the victim of the monopoly which it instituted for beneficial ends. As to the remedy, this we believe will not be in legislation, but in a final appreciation by the courts of the situation which has developed during the past ten years, and which will result in drastic rulings sweeping away the abuse. The fact appears to be that electrical engineering so far as relates to its more important applications, is becoming more and more narrow as a field for invention, using that word in the sense implied in the statute awarding a monopoly to the maker of an invention. On the other hand, the field for the real inventor—the one who explores far away from beaten tracks—remains almost limitless. But the result of his work will not be mere improvements in design and construction clearly indicated by a set of new conditions, but radical departures or new and fundamental conceptions such as actually involve the exercise of the inventive faculty. This needs no further arguing in the day of radium.

The Transformer as a Fire Risk.

Mr. Rice's paper on the above subject, published elsewhere in our columns, raises some very interesting questions. Every one knows the good points of the air-cooled transformer in cheapness, efficiency and convenience, but on the other hand oil insulation has in itself remarkably valuable properties. At very high voltages oil is the only thing to use, but at the pressures in most general use air-cooled transformers are entirely applicable. So far as risks from internal causes go, we think the oil, particularly if rather heavy, has a considerable advantage. An air-insulated transformer can very easily catch fire from a short-circuited coil, and while the insulation is by no means easily inflammable, it will burn very persistently under sufficient provocation even for hours after the forced air supply is cut off. Oil, on the other hand, catches from internal causes only with great difficulty, but if once started in any way burns with a ferocity difficult to overstate. Given a sufficient degree of initial heat and even an oil-soaked brick floor becomes a raging furnace. Floors, in fact, are the most difficult proposition in fire-proof station construction for this very reason. Mr. Rice's suggestion of a separate transformer room, perhaps with an oil pit around the transformers, is thoroughly sound and in accordance with good recent practice. The separate building for transformers is secure in itself, but we think that the trouble of adequately securing the cables leading to it is not justified by any additional security gained in case of fire at the transformers. The leads from generators to transformers and from transformers out of the building, are the weakest points in a good many otherwise very excellent plants, like the switchboard connections. More plants are crippled from troubles of such sort than by accidents to any of the heavy machinery. Modern generators and transformers are wonderfully reliable, and no pains should be spared to make the working connections equally safe.

High Tension Insulation.

No structure electrical or other is stronger than its weakest point, and it is a matter of commonplace electrical knowledge that surface leakage is the weak spot of insulation for high voltage. So far as mere resistance to puncture goes, it is a perfectly simple matter to find insulation capable of withstanding many times the voltages now in customary use. Mr. Moody's preliminary paper to the A. I. E. E. discussion next week on high-tension work, in which he deals with the terminal precautions to be taken with high-pressure transformers, gives a vivid impression of the difficulties which recent practice has heaped upon the already rough path of the electrical designer. It is fairly easy, thanks to oil, to preserve the insulation of the transformer windings themselves at any voltage yet demanded, but to get the high-tension current out upon the line is quite another matter. At pressures of 50,000 volts and upwards there is a vigorous brush discharge from all the wires, and the surface resistance of ordinary insulators becomes greatly reduced, so that there might be sneaking discharges over comparatively long distances. The insulaton of the transformer leads then becomes a problem even tougher than the insulation of the line, since the available distances are very limited in even a large transformer case. The scheme which Mr. Moody seems to have found most efficacious is to provide the lead itself with a local insulating sleeve strong enough to stand up under the working voltage, and then to bring out this insulated lead through a long porcelain bushing sufficient to give an adequate factor of safety. Aside from this, good results have been reached by bringing out the leads through oil tubes.

This matter of what one may call local insulation of high-tension conductors aside from the insulating supports, is one that deserves thorough study just now. Of insulating compounds having good mechanical properties and able to withstand moderate voltages, there are many, but when it comes to dealing with many thousand volts the number dwindles to evanescence. The really good insulators as regards withstanding surface leakage are very few, and none of them are all that they should be mechanically. Hence, Mr. Moody's general scheme of keeping down the potential available for causing surface discharges by insulation applied directly to the conductor as a coating, is both logical and effective. It is worth mentioning that the recent demand for extreme voltages is raising again the question of insulated wire, which has been practically abandoned for high-tension work. We are rather inclined to the opinion that no continuous insulation can be long relied upon even for the purpose of checking the coronal discharge into the air found at high pressures. There are serious oxidation effects at voltages producing a brush discharge in air which no ordinary form of flexible insulation can long withstand. An interesting corollary of the question here discussed is the proper factor of safety to be used in high-voltage insulation. Ordinary current practice requires a factor of 2 or 3, rarely more. The lower figure seems rather small unless one can be assured immunity from abnormal potentials on the line. At voltages from 20,000 to 40,000 the methods of insulation now in use, both on the line and in apparatus, seem to be fully adequate, but there are so few plants running at pressures above 40,000 volts that it is hard to get a line on the real behavior of insulation. In the region of pressures where coronal discharge is prominent, the situation is greatly complicated and insulation is a formidable question. The oil transformer renders it possible to get the pressures with reasonable facility, but insulation outside of the protecting oil is quite another matter.

The Inaugural Address of the President of the Institution of Electrical Engineers.

The inaugural address last November of President R. K. Gray, of the Institution of Electrical Engineers in London has been published in a recent number of the *Transactions* of that body, and contains some very interesting facts and suggestions. The Institution of London was founded in 1871, thirteen years before the foundation of the American Institute of Electrical Engineers. The American Institute had at the beginning of the year a total membership of 2,800 after nearly twenty years of existence. The total membership of the British Institution at the same time was about 4,800 after nearly 33 years of growth. It is pointed out in the report that two-thirds of all the electric lighting in the United Kingdom is in municipal plants and only one-third in the plants of companies. In fact, if London, the main home of the companies, be excluded from consideration, nearly seven-eighths of the lighting is in the hands of municipalities. In the United States only about 5 per cent. of the lighting is municipal. The average rated capacity of a British station is about 1,400 kw, while that of the United States is only 340 kw. The total rated station capacity in Great Britain is, however, given only as 480,000 kw, while in the United States the total in June, 1902, was 1,200,000 kw. Consequently, while the average British station is four times as large as a United States station, the United States lighting is nearly three times as large as the British.

A noticeable feature in the address is that while candle-powers of lamps are less in Britain than with us, so that the standard lamp is the 8-cp lamp, yet the distributing pressures are generally higher, and 200-volt lamps much more common. In this country the large stations which commenced operations upon 110-volt lamps with the three-wire system, have not judged it to their advantage to change to 220-volt pressures. Nernst lamps are spoken of as a factor in British electric lighting, and also osmium lamps, which latter are curiosities in this country. They are described as having, in 25 and 30-volt pressures, an efficiency of ⅔ candle per watt and as showing but little diminution in light or efficiency after 800 or 1,000 hours of burning. The vertical-shaft design of steam turbine, now familiar in this country, is criticised, in comparison with the horizontal-shaft design, without, however, any facts in support of the judgment. The project of utilizing the Zambesi Falls for electric power transmission is alluded to. It is not generally known by Niagara worshippers in this country that the Victoria Falls of the Zambesi waste power to the estimated extent of 26,000 megawatts, or are five times as wasteful as the Niagara Falls, which before engineers attacked them wasted about 5,200 megawatts, or 7,000,000 hp. The plans under operation and present contemplation at Niagara propose to save about one-seventh of this for the world, or some 750 megawatts.

The total length of submarine cable laid in the globe is stated as 222,253 nautical miles, employing 47 cable ships, all told. It is some comfort to reflect that there is now as much cable laid on the globe as would reach in one length to the moon and leave a fair excess for slack. It is sad to see a President of an Institution of Engineers trying to withstay the inevitable stride of progress by advocating the general retention of the absurd old English weights and measures, that we also are yoked to. The statement is gravely made that in France precious stones are still bought in carats, milk in pintes, gravel in toises, and so on for about twenty indictments. The statement is true to the extent that these old units are still occasionally met with in France, just as here, in the United States, we occasionally yet find prices in terms of the shilling. But it is recognized by persons who have lived in France that it is just as unreasonable to speak of the general use of the old terms and units in that country as to say that the pound, shilling and penny still prevail here.

It is actually urged that the litre and the gramme are too limited to apply to all the things met with in daily life. The kilogramme is all very well for physics, but it is not adapted to charcoal. If we carry this proposition to its natural terminus, we should make the English weights and measures still more diffuse. Land should be exclusively measured, for example, in square chains, water in nothing but fathoms, houses only in feet, machines only in inches, horses in hands, men in cubits, and so on indefinitely. Particularly avoid common factors. What visions of rapture this exclusiveness of quantitative relation must conjure up in the bewildered imagination of the schoolboy! Whatever we learn, let it be hard; and whatever we say, let it be ambiguous. A large share of this excellent address is devoted to the recent advances in electrochemistry. The rate of growth of electric railways and the rate of increase in available electric pressures for transmission are also commented on at some length. The general breadth of topics and treatment is one of the noticeable features of the address.

A Union Engineering Building in New York.

New York City, already adorned with some fine buildings devoted to the arts and sciences, is now to enjoy the possession of a great central home for engineering, due, very appropriately, to the initiative and generosity of Mr. Andrew Carnegie, and carrying out ideas with which the public has become more or less familiar during the past year. The following letter gives the facts briefly:

Andrew Carnegie, 2 East 91st St., New York.
March 14th, 1904.

Gentlemen of the Mechanical Engineers; Institute of Mining Engineers; Institute of Electrical Engineers; Engineers' Club of New York:

It will give me great pleasure to devote, say, one and a half million of dollars for the erection of a suitable Union Home for you all in New York City. With best wishes, truly yours,

(Signed) Andrew Carnegie.

It may be stated that the three national engineering societies named and the Engineers' Club, which, by reason of its widespread membership is also increasingly national in character, have, with the unanimous approval of all the memberships, already taken active steps to put into being the splendid trust for engineering thus created by a man whose own career has illustrated the upgrowth of the engineering and industrial arts in America. Mr. Carnegie is also a member of the Mechanical and Mining Engineers and of the Club. The total amount involved is not less than $2,500,000, for, in addition to the amount given by Mr. Carnegie, a sum of over $500,000 represents the investment in land for the three societies on West Thirty-ninth Street, between Fifth and Sixth Avenues; while the Engineers' Club has also acquired valuable land for its own purposes on West Fortieth Street, immediately facing the New York Public Library. The Union Engineering Building will probably be 12 stories in height, and will be laid out expressly with an eye to the services required of it. In many respects it will be unique. The three national engineering societies made trustees by Mr. Carnegie will have large headquarters there; and already several kindred bodies have made urgent requests for accommodation. There will be four or five auditoriums of different size, notably one to seat 1,200 to 1,500 persons; and all will be appropriately equipped for scientific meetings, lectures and demonstrations. Above all, there will be an engineering museum and a noble library hall, where all the libraries concerned will be grouped and consolidated, yet each section administered by its respective Society librarian and each adding to its own specific literature, so as to avoid duplication of outlay for books or periodicals. It is proposed, moreover, to co-operate intimately with the New York Public Library, nearby, along these lines of work, so that nowhere else in the world can the student or practitioner find thus freely available the whole literature of engineering and technical industry. The three libraries assembled in this manner will even at the outset include some 50,000 volumes, many of them great rarities of inestimable price.

The three societies, each of course maintaining its identity and autonomy, will themselves need considerable room in the new building, which it is hoped to have ready in 1906. They have a total membership to-day of over 9,000, and are growing at a rate of between 10 and 15 per cent. annually. They administer a total income of $135,000 annually and in assets of all kinds have property to the value of between $250,000 and $300,000, a sum to which the gifts of individual members are now adding rapidly. The sister technical societies asking for quarters and facilities represent also another great body of over 5,000 members, engaged in all branches of civil, mechanical, electrical, municipal engineering, etc. Large, therefore, as the Union Engineering Building, with its frontage of 125 ft. on five lots, may seem, it bids fair from the start to find every inch put to fructifying use. The Engineers' Club Building, a separate entity, will immediately flank the Union Building, the two sharing the same resources of light, heat and power, and being most advantageously situated for intercommunication and mutual social benefit. The club, with a long waiting list, has just increased its membership to 1,200, and administers a budget of about $120,000 a year. The buildings, facing thus on two streets, are to harmonize as to architecture, as they do virtually in function, as homes of engineering, and their central position commanding all lines of travel at the very heart of the city, insures the acme of convenience to visitors from outside the city or from abroad, as well as to all local members.

The three societies provide the land, but in the meantime Mr. Carnegie has promptly acquired it for them. The leases run out about July 1 and work will then begin forthwith and be pushed ceaselessly to completion, as the building is in reality sorely needed by the bodies that are to occupy it, and that now chiefly occupy rented quarters ill-suited to their purposes. The Engineers' Club has also already made purchases of land for itself on West Fortieth Street, not far from the new Republican Club opened recently. Plans for the architectural part of the undertaking have already been drafted, and the architects will soon be selected. The representatives of the four bodies interested as the direct beneficiaries and trustees of Mr. Carnegie's splendid gift to engineering are as follows: American Society of Mechanical Engineers—Prof. F. R. Hutton, C. Wallace Hunt, J. M. Dodge. American Institute of Mining Engineers—Dr. A. R. Ledoux, Theodore Dwight, C. Kirchhoff. American Institute of Electrical Engineers—C. F. Scott, Dr. S. S. Wheeler, Bion J. Arnold. The Engineers' Club—J. C. Kafer, W. H. Fletcher, T. C. Martin. These as a conference committee have carried the matter patiently through its earlier stages and are now vigorously engaged in working out all the details of an enterprise which, recognizing frankly the close interdependence of all branches of engineering, endows them jointly with means for professional and educational work never before enjoyed in any country by such organizations, or on such broad conditions of public welfare; leaving, nevertheless, to the societies their distinctive and individual conditions of existence.

Tesla's Split Phase Motor Patent Decision.

Judge Hazel, of the United States Circuit Court of the Western District of New York, has handed down an opinion sustaining the two Tesla fundamental patents (Nos. 511,559 and 511,569), covering the split-phase motor. The suit was instituted by the owners of the patents against the manufacturer of a wattmeter, and the court held that the wattmeter infringed the patents for the reason that it depended for its action on two currents differing in phase, derived from a single supply circuit.

The patents involved were the same that figured in the Catskill case, in which suit they were sustained by the Circuit Court, but declared invalid upon appeal. This reversal was on the grounds that the publication of a magazine article on April 22, 1888, by Prof. Galileo Ferraris fully described and disclosed the system covered by the patents. This publication was held to be prior to the date of the invention in suit and constituted an anticipation.

Judge Hazel, in his opinion, disagrees very materially with Judge Townsend, who wrote the opinion on appeal, declaring the patents invalid. The conflict arises from the different weight which the two judges gave to the testimony of the several leading witnesses, this testimony being held by Judge Townsend to be inconclusive, and by Judge Hazel to establish clearly that Tesla conceived the invention prior to the publication of the Ferraris article. Judge Hazel considers that, according to the testimony, Tesla conceived his split-phase invention in his laboratory at 89 Liberty Street, New York, and completed the same in the month of September, 1887; and that he made the disclosure thereof to others during the fall of 1887, especially to Mr. Brown and Mr. Nellis, and subsequently in the month of April prior to the Ferraris publication to his solicitor, Mr. Page.

Washington Meeting of the American Electrochemical Society.

The fifth general meeting of the American Electrochemical Society will be held at Washington, D. C., April 7, 8 and 9, 1904, in the hall of Columbian University. Thursday and Friday afternoons will be devoted to visits to scientific laboratories, government institutions and various points of interest in and about Washington. On Thursday evening the presidential address will be delivered and will be followed by a complimentary smoker. Friday evening there will be a subscription banquet at the Shoreham, corner Fifteenth and H Streets, N. W., at which hotel headquarters will be maintained. Among the papers announced are the following:

"The Composition and Resolution of Voltages," by Dr. J. W. Richards; "Notes on the Industrial Electrolysis of Water," by Mr. W. S. Landis; "Standard Cells," by Dr. F. A. Wolff; "Electric Smelting Experiments for the Manufacture of Ferro-Nickel from Pyrrhotite," by Ernest A. Sjostedt.

Reconstruction of the Zanesville, O., Railway, Light & Power Company's Property.

THE property of the Zanesville Railway, Light & Power Company has been undergoing an almost complete reconstruction during the past eighteen months. As many other properties are in a position where such reconstruction is being considered, the present article, telling how this reconstruction was accomplished in Zaneville and the results, will no doubt be of interest. The old power plant of this company consisted mainly of high speed simple non-condensing engines and a conglomeration of belts and line shafting for transmitting the power to generators such as is familiar to most of our readers. This plant is to be entirely abandoned.

The new plant consists entirely of steam and water turbines. There are no reciprocating engines driving generating machinery in the plant.

LOCATION.

A remarkably fortunate location was selected for the new plant, as shown in Fig. 1. It is on the bank of the Muskingum River, between the river and a canal maintained by the Government. In order to supply water to this canal, the government maintains a wooden crib dam in the Muskingum River just above the power plant, as seen in Fig. 1. The water power obtained by this company is therefore secured at no expense for the maintenance or construction of a dam or canal. The only expense connected with the development of the water power has been the building of the water power station itself. In this plant, water power is not depended upon entirely, as there are times when, owing to the great amount of flood water going over the dam, the head of water at the power house practically disappears. A steam power plant sufficient to carry the full capacity is therefore placed in the same building, but it is expected that water power will be sufficient during a large portion of the time to operate the plant. Since in this case the expense of the hydraulic development was comparatively small, the engineers considered that they could well afford to install a hydraulic plant for the sake of power that could be obtained, even though this power could not be relied on every day in the year.

Just below the power house is a bridge, and from the street railway tracks on this bridge a spur is run to the power house for the purpose of carrying coal and other supplies. A side track of the Baltimore & Ohio Railroad also reaches the plant at one end. The power house is located on a solid ledge of rock, as can be seen from Fig. 3, which was taken during construction. This shows the ledge of rock on which the power house and the excavation made for the tail-race and also the concrete arch construction over the tail-race.

Fig. 1.—General View of Power Plant at Zanesville, Ohio.

CONSTRUCTION AND ARRANGEMENT OF BUILDING.

The water passes under the down stream end of the building. The ordinary level of the tail water is thirteen feet below that of the head water, giving a 13-ft. head on the wheels. This head disappears in times of freshets, as maximum high water comes very nearly to the top of the concrete foundation wall, which is carried up to the level of the engine and boiler room floors.

The up-stream end of the station contains the steam turbine units. Fig. 2 is a section through this end of the station. At the right are stairs leading to the switchboard gallery. The basement floor is thirteen feet below the engine room floor; the basement containing the turbines and condensers, while the generators on the vertical turbin shaft are above the level of the main floor. All the foundations of the building are concrete laid on solid rock. The roof is slate with copper gutters. The floors are black and white tile with white tile wainscotting. The building is of Zanesville pressed brick.

APPARATUS IN STATION.

The five water wheels seen in the sectional elevation in Fig. 2 are each 51-in., 275-hp vertical shaft turbines, of the open-flume type, made by the Stilwell, Bierce & Smith-Vaile Company. These turbines run 80 revolutions per minute and are geared through bevel gears to a line shaft running 200 revolutions per minute. On each end of this line shaft is a 375-kw General Electric, 60-cycle, 2,300-volt generator. Fig. 5 is a view in the shaft house, showing the shaft, bevel gears and Lombard water wheel governors. The shaft house is partitioned off from the generators at either end.

In the steam turbine room, Fig. 6, are two 500-kw Curtis steam turbines, designed to operate at 180 pounds steam pressure, in connection with Stilwell-Bierce surface condensers. Fig. 7 shows one of these turbine units with its condenser piping. The centrifugal circulating pump is motor driven. Provision has been made in the generator room for two more steam turbine units of this size. The rotary converters mentioned later are also in this room.

In the boiler room resting on a concrete floor over the head-race are two 380-hp Heine water tube boilers, with two Stilwell-Bierce feed pumps. The boilers are hand-fired. Coal is shoveled directly from the cars on the siding into the space in front of the boilers. Provision has been made for doubling this boiler capacity.

About 25 per cent. of the load of the station is supplied to alternating-current lighting circuits. The remainder is used in rotary converters to give 550-volt current for railway use and 110 volts for the three-wire direct-current network.

For railway purposes one three-phase transformer takes the 2,300-volt current and reduces the voltage for use in a six-phase, 60-cycle rotary converter for supplying the street railway.

To supply the direct-current lighting network two three-phase transformers step down the 2,300-volt three-phase current for use in two 240-volt rotary converters. The balancing is done by a connection of the neutral of the star-connected rotary converters.

Both the railway and lighting rotary converters are supplied from the same generators. This has been made possible by connecting in multiple with the railway bus-bars, 256 cells of Chloride accumulator. This storage battery is connected in series with a differential booster, which causes the battery to take the fluctuations of railway load and leave a practically steady load on the generators. The cells of this battery are type G, with 17 plates per cell. The tanks are large enough to allow 50 per cent. increase in plate surface. The differential booster is large enough for the ultimate capacity of the cells. This battery is rated at 640 amperes at the one-hour rate of discharge. Provision has also been made in the battery room for a battery to operate in connection with the three-wire direct-current lighting system. The battery room is shown in Fig. 4.

The value of a battery was forcibly demonstrated last winter during the holidays. The maximum railway load amounted to 660 kw. If there had been no battery, this would have been beyond the capacity of the water supply which was then available for use. The average load was only 220 kw. The battery took the fluctuations so that the plant was operated with one wheel at full gate and one wheel at sixteenths full gate.

No exciters have been provided for this station for the present. The engineers considered that with the battery in case all the direct-current machinery should be shut down, current for excitation can be obtained therefrom.

The battery room is on a floor above the generator room. It has the regular floor now commonly employed in storage battery rooms, consisting of tile laid in asphaltum, and is drained with lead-lined iron pipes.

The high-tension switchboard in the gallery was furnished by the General Incandescent Arc Light Company, and has "G. I." hand-operated oil switches. Two General Electric potential regulators will be employed on the alternating-current lighting feeders. These regulators will be operated to raise and lower the voltage, by means of small alternate-current motors. The transformers are air-cooled.

As stated before, the water wheels are governed by Lombard governors. The speed of the wheels can be varied from the switchboard by means of a direct-current motor at the governor for shifting the governor weight.

Street lighting for the city which has been done formerly by direct-current arcs will be done hereafter with 6.6 ampere G. I. differential enclosed arcs, 250 in number, 25 on a circuit.

ECONOMIES BY THE RECONSTRUCTION.

Of course, a great economy in operation is anticipated as a result of the abandonment of the old power station. As said before, much of the total output in a year will be generated by water power, and therefore at no fuel expense. That portion of the power supplied by steam should certainly be generated with much greater economy than in the old plant. The old plant used twelve pounds of coal per kilowatt hour. The new 500-kw Curtis turbine units are guaranteed to operate with twenty pounds of steam per kilowatt hour. If eight pounds of water can be evaporated per pound of coal in the boiler plant (which the engineers assume is a reasonable figure), the turbines would give a kilowatt hour for two and one-half pounds of coal. The repairs in the old plant were enormous. In the new plant it is believed that they will be very low, as there are so few moving parts, as compared with the old, and the electrical apparatus is confined to large units of modern construction. In the old plant seventeen men were required for its operation. In the new plant six men are required.

Making allowance for interest and depreciation, the engineers estimate that there will be a yearly saving of $18,000, as compared with the operation of the old plant. The cost of reconstruction, which includes also rebuilding of much of the street railway track and the purchase of entirely new rolling stock, so as to bring the street railway system to a standard guage, was $400,000. The present connected load is the equivalent of about 14,000 16-candle power lamps. Excluding the small sized motors, there is a motor load of 300 kw, distributed among 35 motors.

Since the present management took charge the earnings have increased about 20 per cent. Last year railway earnings were about $110,000 and light $65,000. The operating expenses are about 55 per cent. of the gross earnings. The base rate for power and light is 10 cents per kilowatt hour. About 350 kw additional power load is soon to be taken on, and it is further anticipated to transmit power to nearby pottery towns which, as is well known, are good power consumers. Coal costs the company $1.40, delivered. The company now has outstanding $1,000,000 in bonds and $1,000,000 in stock.

RECONSTRUCTION OF THE ZANESVILLE (OHIO) RAILWAY, LIGHT & POWER COMPANY'S PROPERTY.

and Chicago, undertook the reorganization of the properties now merged in the Zanesville Railway, Light & Power Company, in September, 1902, their contract providing for, not only the reorganization of the securities of these properties, but also for their complete physical and operating reconstruction. Kleybolte & Company, in turn, contracted with H. M. Byllesby & Company, of Chicago, for all the engineering work connected with the rebuilding of the property, the designing of the new power house and its contents, and H. M. Byllesby & Company, in connection with Messrs. Kleybolte & Company, also had charge of the reorganization of the operation of the properties.

Under the reorganization, all the former operating officials were retained; Hon. F. A. Durban, of Zanesville, being elected president; H. M. Byllesby, vice-president and engineer; W. A. Gibbs, general manager and assistant treasurer; W. D. Breed, of Messrs. Rudolph Kleybolte & Company, secretary and treasurer. Mr. Gibbs had been in charge of the properties under the former management for several years, and under the reorganization his powers and duties were largely increased and he had a prominent part in the reorganization of the operating conditions and in the reconstruction of the properties in connection with H. M. Byllesby & Company. Mr. Gibbs, together with E. C. Braun, one of the engineeers of H. M. Byllesby & Company, had charge on the spot of the reconstruction of the property.

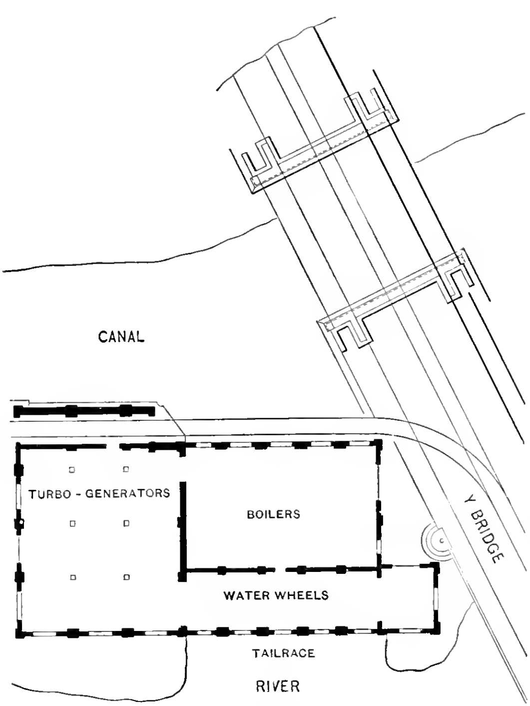

FIG. 8.—PLAN OF POWER HOUSE, ETC.

The street railway system, comprising some 14½ miles of track, was of 5-ft. 2-in. guage laid with rails ranging from 36 to 70 pounds per yard. Along with the reconstruction of the power house, the street railway system was reconstructed to bring it to standard gauge. This also called for a new rolling stock. The track as reconstructed now consists of 70-pound standard A. S. C. E. T rail in dirt streets and 70-pound Shanghai T in paved street. Eight of the 14½ miles of track is in paved street. Ties are 6 in. x 8 ft., laid two feet between centers. Atlas rail joints were used. The trolley is No. 0000 wire. The bonds and overhead material were furnished by the Ohio Brass Company. These cars are equipped with four 25-hp G. E. motors. Eighteen cars are operated during rush hours and ten upon ordinary schedule.

Niagara Beauty or Niagara Power.

At the hearing before the New York State Senate Committee on Miscellaneous Corporations at Albany on the bill to increase the water rights of the Niagara, Lockport & Ontario Power Company, Charles M. Dow, president of the Board of Commissioners of the State Reservation at Niagara, vigorously objected to the measure. Among other remarks, he said: "Owing to the greater declivity of the river bed on the Canadian side, as well as the wider expanse of the Horseshoe Fall, it is estimated that only one-fifth of the whole volume of the river passes over the American fall. Furthermore, owing to the difference in elevation of the Canadian and American river beds, the water has a tendency to gravitate toward the Canadian fall, and the American fall is the first to show the effect of any subtraction of water from the river above. As the general depth of the water on the fall is only about four feet, and as the elevation of the American fall is something like six or seven feet above that of the Canadian fall, it is apparent that the American fall might be made entirely dry while water still poured over the Canadian fall. That such a discrepancy would appear in the event of the diversion of a sufficient amount of water is not simply a theory; the fact was demonstrated in 1848, when the flow of the river was diminished by an ice blockade at the foot of Lake Erie, and on a lesser scale by more recent ice gorges.

"From the foregoing it will appear that the diversion of 20 per cent. of the water of Niagara River would be sufficient to render the American fall as dry as the once famous cataract of Lodore in England. Now, let us see what the State has already done to accomplish such a disastrous result: The reservation had hardly been created, for the express purpose of preserving the scenery of the falls, when the Legislature began, with singular inconsistency, to give away gratuitously the very water upon which the existence of the falls depends. Seven corporations were granted charters to take water from the Niagara River, between 1886 and 1894, besides another corporation which is taking water without authority, making eight American corporations which have either been authorized or are taking water without authority from the river. There are two Canadian corporations, for which the New York Legislature is not responsible, of course, but the effect of whose operations upon the flow of the falls must be reckoned with.

"Some of these corporations are limited in the amount of water which they can divert. More are unlimited. One limited American company alone is authorized to develop 200,000 hp, requiring 6 per cent. of the volume of the river. With a similar development by its corresponding company on the Canadian side, the flow of the river will be diminished about one-eighth—sufficient to dry up the American fall, according to one estimate. A similar development by all of the companies in existence would rob Niagara of one-third of its volume, and insure the obliteration of the American fall beyond a peradventure."

Evansville Municipal Telephone Company's Trouble.

There is trouble existing among the stockholders of the Evansville Municipal Telephone Company, which threatens to disrupt the organization and defeat the unique scheme of its chief promoters. Ten months ago the City Council of Evansville refused to renew the franchise of the Cumberland Telephone Company, and a movement was started by Mayor Covert and others to organize a municipal company to install a plant in the city and drive the Cumberland Company out of the city. Stock has been subscribed to the amount of $78,000 and a call was issued nine months ago for a payment of 30 per cent. of it. According to the plans and promises of the promoters, the stockholders were to receive an annual dividend of 7 per cent. and all other surplus was to go toward retiring the stock. It was figured that at the end of 20 years the city would own the plant.

Out of patience in waiting to see something done, stockholders representing 430 shares of stock held a meeting recently and demanded that the directors make a statement. There were many heated debates and the directors were charged with being negligent and with not having the municipal idea at heart. Those present insisted that something be done toward installing a plant and threatened the directors that unless they make a report a receiver will be asked for and the company's business closed out.

The Electric Power and Transmission System of Schaffhausen, Switzerland.—II.

(Concluded.)

STORAGE BATTERY.

The storage battery which is used for reserve power for the railway service is located in a separate building on the left side of the Rhine between the two power stations. The battery consists of 276 elements and has a capacity of 165 amp.-hours. The battery room is illuminated by four incandescent lamps. A repair shop is located in the same building.

OPERATING COMBINATIONS.

Under normal conditions the lighting circuits are fed by the two single-phase alternators in the lower station, and the power circuits (including the railway) are fed by the two alternators in the upper station. Should an accident occur the single-phase-polyphase reserve generator in the lower station can be operated in parallel on the lighting circuit. If, however, one of the power service generators in the upper station is disabled the reserve generator can be used for the power circuits. By the use of this reserve generator danger of service interruption is reduced to a minimum.

SINGLE-PHASE DISTRIBUTION.

Six cables leave the lower station carrying single-phase current for lighting and small power work. They are carried in wooden casings over the iron bridge to the shore. Four of these cables have a cross-section of 2 x 60 mm. and two are 2 x 20 mm. Each cable is double and concentric, one part being for the outgoing current and the other for the return.

One circuit, forming the core of the cable, consists of copper strand insulated and lead-covered. The other circuit consists of copper strand spun around the inner lead covering. This strand is also insulated and protected by a double cover of lead. To prevent injury in handling, the complete cable is covered with asphalted linen. The resistance between the inner and outer cables is 1,120 megohms and between outer cable and earth 1,140 megohms.

Both primary and secondary cables are laid in clay pits filled with fine sand. When primary and secondary cables are laid in one pit, additional safety is secured by laying the primary cable about 120 mm. lower than the secondary. This makes it possible to repair the low-tension cable without coming into contact with the high-tension cable. Wherever possible, branching of the high-tension cables takes place in the transformer stations. The high-tension cables consist of 7.511 km. 2 x 20 mm. concentric cables, 2.799 km. 2 x 40 mm. concentric cables and 5.645 km. 2 x 60 mm. concentric cables, making a total length of 15.955 km (9.6 miles).

The transformers, which reduce the 22,000-volt current to 120 volts, are set up in cylindrical iron houses. Two types are used for underground entrance of the primary cables and underground exit of the secondary cables. For underground primaries and overhead secondaries these houses are furnished with masts. Those for overhead work are outside the city limits.

Each of the four door houses has room for two 20-kw transformers. On one side of the interior there is an iron framework for carrying the transformers and a double-pole switch controlling the high-tension current going to the next transformer station. The second side carries two double-pole, high-tension switches operated from the third side to control the transformers. The fourth side has two marble panels, the upper one carrying two double-pole, low-tension switches for transformer control, and protective devices, and the lower panel a double-pole switch for the outgoing low-tension cables as well as safety contrivances.

The houses arranged for overhead work are, in addition to the above, equipped with lightning arresters.

Besides these transformer stations there is also one located at the center of the city. It is reached by ladder from the street surface through a shaft covered by wooden and iron covers. This room contains four transformers with switchboard and arrangements for ventilation and sewerage. There are in use 28 transformer stations using 33 transformers, taking 630 kw.

As the tension of the two-wire system is 120 volts and of the three-wire system 240 volts, all transformers have two secondary windings, which can be arranged in parallel for the former system and in series for the latter. All wires of the three-wire system are buried, but in general the two-wire system is an overhead one.

FIG. 5.—SECONDARY SIDE OF TRANSFORMER HOUSE.

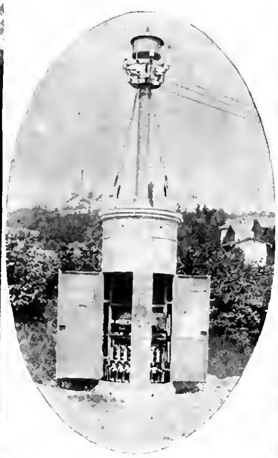

FIG. 6.—TRANSFORMER HOUSE.

FIG. 7.—HIGH-TENSION SIDE OF TRANSFORMER HOUSE.

The overhead wires are carried on double-covered insulators mounted on zinced iron supports attached to wooden poles 30 to 32 ft. high. These poles are covered with cast-iron caps and at exposed places are also furnished with lightning protection.

The length of the buried secondary network, consisting of 15 mm., 25 mm., 50 mm., 100 mm., 150 mm., and 200 mm. cables, is 16.327 km. (10 miles). The total length of the overhead secondary wires is 36 miles and weighs 9.2 tons. The total number of private consumers is 353.

All public arc lamps are separately shut in and out of circuit by water-tight switches. An automatic timing method is also being tried at present. The public incandescent lamps are all of 25 cp. There are in use 11,007 incandescent lamps and 88 arc lamps. There were also 22 motors on this circuit using in all over 39 hp. The total capacity of this system is 675,462 kw-hours.

POLYPHASE DISTRIBUTION.

Two triple 3 x 60 mm. cables laid in clay pits are led from the upper station to the lower one. At the latter station the cables branch, one being led to the three-phase motors running the railway generators and the other to a city distributing station. All of these cables are triple, have double lead covers and asphalted linen protection. The middle insulation resistance of each cable is 2,500 megohms per km.

From the main polyphase distributing station cables are led to ten sub-stations as well as a number of factories. Each station is furnished with a three-pole switch and other regulating and protective devices. Five of these polyphase stations also contain transformers and controlling apparatus.

Nine 1,900-volt, three-phase motors taking a total of 815 hp are used on this system, the largest being the two 150-hp motors used in connection with the railway generators. Another 150-hp motor is used in a worsted mill. The other motors are distributed among a dyeing establishment, nail factory and the Engestieg, Rheinalde and Breite pumping stations.

The low-tension polyphase motors on this system operate at 190 volts. At present there are 28 in use, totaling 318 hp. The largest motor used has a capacity of 30 hp. The total product of this system in 1901 was 1,144,721 kw-hours, and the maximum for one day 5,025 kw-hours.

SCHAFFHAUSEN CORD WORKS.

The power for operating the machinery in the Schaffhausen Cord Works is transmitted from the upper station through a 3 x 250 mm. high-tension cable. This cable divides into four parts at the factory switchboard. One of these three-phase branches gives but two phases to a 5-kw transformer which steps down the voltage to 240 for lighting the works. If necessary, the lighting circuit can be connected to the city lighting mains. This circuit feeds 230 16-cp incandescent lamps and three 14-amp. series arc lamps.

All the motors are operated at 390 volts. The motor equipment comprises six 50-hp motors and one 35-hp motor. All motors transmit power through belting.

SCHAFFHAUSEN WORSTED MILLS.

As has been stated before, the Schaffhausen Worsted Mills receive the power generated by two hydro-electric sets in the lower station. Current is transmitted by two overhead cables, each consisting of two cables each made up of 37 strands 32 mm. diameter. The overhead transmission in crossing the Rhine has a single span 100 m. long and enters the motor station of the worsted mills.

In this station the cables are led to double-pole switches, which

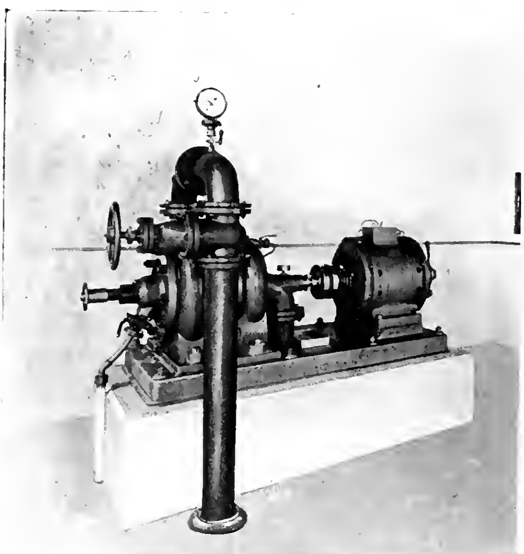

FIG. 8.—35-HP, THREE-PHASE MOTOR, BREITE PUMPING STATION.

are opened during lightning storms and outside of working hours. The cables also have lightning protection. They are led underground from these switches to the distributing switchboard, which contains the necessary instruments for controlling the branch circuits.

The motor station contains a 350-hp twin motor, which, through a rope drive, formerly operated the chief transmission system of the mills. This twin motor, which consists of two dynamos, is no longer used as a motor, but serves as a reserve generator operated by a steam engine in case the outside transmission system fails.

Every motor is operated at 650 volts and is furnished with a separate control panel including two-pole switch and ammeter. The present motor equipments of the mills include one 135-hp motor, five 60-hp motors and two 30-hp motors.

SCHEDULES.

The following charges are made to power users:

For all purposes, except lighting, 3.86 cents per kw-hour. The rebates are the same as those given below for lighting circuits; but there is a minimum annual charge of $9.65 (50 francs) per kw capacity of the individual station used by the consumer. The lowest

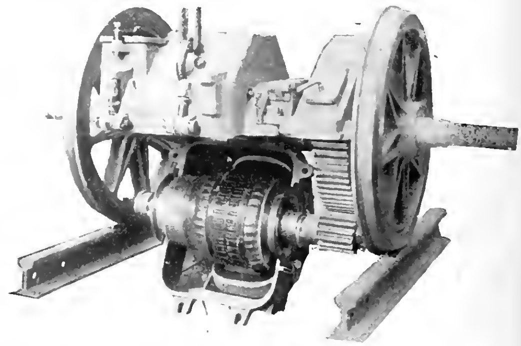

FIG. 9.—RAILWAY MOTOR.

price, namely, 3.86 cents, applies only from midnight to twilight. If the motors are used at night during lighting hours special terms are made.

Light consumers are charged 11.58 cents per kw-hour., and a minimum of $6.95 per annum.

In the following table the second column gives the rebate for using more than the amount specified in the first column opposite:

Dollars.	Rebate.
19.30	2 per cent.
48.25	4 " "
96.50	6 " "
193.00	8 " "
289.50	10 " "

965.00	20 " "

Larger special discounts are given to consumers using more than $1,158 (6,000 francs) of power.

The minimum annual cost per horse-power using separate polyphase stations is $28.95 for low-tension motors and $24.13 for high-tension (2,000-volt) motors of 50-hp or greater capacity.

The single-phase circuits may be used continuously except for two to four-hour intervals, on Sundays and holidays. The polyphase system gives current every day except Sunday and holidays from 6 A.M. to 7 P.M. As the railway depends on this system consumers do not receive current outside of the hours named unless the conditions are favorable.

THE STREET RAILWAY SYSTEM OF SCHAFFHAUSEN.

The Schaffhausen-Neuhausen line begins at the southern end of the steam railroad station in Schaffhausen, passes to the Oberthor, crosses the government steam railroad below grade and ends in the center of Neuhausen in front of the Hotel Rheinfall. The second line (Breitelinie) runs between the railroad station and Marksmen's House. The third line connects the Emmersburg quarter and the railroad station.

All of the lines are single-track construction with turn-outs averaging 263 ft. in length. The distance between track centers is about 8 ft., leaving a clearance of 20 in. between cars passing each other. The minimum distance between outer rails and curb is 3.28 ft. The track is divided as follows on the Neuhausen and Breitelinie lines, respectively: Straight track, 53 per cent. and 66 per cent., curved track, 47 per cent. and 34 per cent.

The Neuhausen line climbs a 5.4 per cent. grade on the way to Oberthor and a 4.6 per cent. grade between the steam railroad crossing and Scheidegg. The Breitelinie route has a maximum grade of 8.1 per cent.

All of the lines run on the public highway, and as the railheads are flush with the street, wagon traffic suffers no interference. The rails are laid on a foundation made up of large stones covered by rubble.

The track joints are made by mitering in a way common in Germany, milling out a portion of the head of the rail each side of the joint and extending the top of the outer angle bar so that it fits into the milled section and carries part of the weight from the wheel. Edison-Brown plastic bonds are used throughout.

The car barn, which has a capacity of twelve cars, is constructed of brick with skylights and wood and cement roof. It has two pits and four trucks, and is lighted by four arc lamps and ten incandescent lamps. A smithy and repair shop adjoin the car barn. The repair shop contains two lathes, planing machine, boring machine and grindstone. All of the machines are operated through belting by a 2-hp Oerlikon motor.

The line voltage is 550 and the drop is not permitted to exceed 50 volts. Current is transmitted by buried cables from two motor-generator sets located in the lower power station. One of these sets is always held in reserve. The motors receive current either from the upper station or from the reserve generator in the lower station.

The twelve-pole motors of these sets are built for 150 hp at 490 r.p.m., using 2,000-volt, three-phase current at 50 cycles. Each motor is connected to the corresponding direct-current generator by a flexible coupling. Each dynamo generates 182 amp. direct current at 550 volts.

All the trolley poles are constructed of steel. The power wire is made of hard-drawn copper 8 mm. thick and is supported by 6 mm. steel span wires 20 ft. above the rails. Return is made to the power station through the rails. The lines are protected by lightning arresters mounted on poles, and an automatic arc extinguisher where the feeders leave the power station. Steel guard wires have been placed parallel to the power wire to prevent contact with falling telephone or telegraph wires. These additional wires are attached to a 6-mm. copper wire connected to the rails.

The rolling stock consists of nine single-truck motor cars, one sanding car and one repair car. The mechanical part of the motor cars was built by the Schweizerischen Industriegesellschaft, of Neuhausen. The motors can be inspected from the top by lifting a portion of the car floor.

Each car has two 24-hp motors made with a close-fitting steel frame. The laminated poles are screwed to the inside of the frame. The frame is divided into two parts and may be opened either from the top or bottom, making all parts easy of access. Current is taken through four collector brushes. These brushes are so placed that they may be quickly removed from above even when the motor is mounted for service.

The armature has 37 slots containing 36 wires triple-covered with silk and varnished. The four poles, which are connected in series, have 200 turns of wire each.

The motors are series-coupled when running slowly, and parallel-coupled at high speeds and heavy loads. For control there are four series, six parallel and six braking positions. One of the motors can be cut out of circuit by lifting a contact on the reversing handle without interfering with the running and braking of the car. All of the controller contact fingers are furnished with arc extinguishers. The total cost of the street railway system was $112,000 (561,060.4 francs), or $23,000 per mile. The total number of passengers during 1901 was 481,143, or 6.5 per trip. To carry this traffic required 131,541 kw-hours. Fares are paid according to the zone system, the first zone costing 2 cents and 1 cent for additional zones. The highest fare possible is 5 cents. Reduced-fare tickets are sold to school children and workmen. Passes are granted to employees of the railway.

The operation of the system (exclusive of power stations) requires the services of twenty-nine men, including a director, starter, cashier, two ticket agents, three shopmen, three trackmen, nine motormen and nine conductors.

Electrical Exposition at Warsaw.

An electrical exhibition will be held at Warsaw, Poland, this summer to which it may be to the advantage of American manufacturers to send exhibits, in view of the fact that it is believed locally that the current year has opened a period of great industrial activity, especially in the electrotechnical branch. Articles for exhibition will be admitted free of duty. It is hoped that the Russo-Japanese war may not distract public attention from the affair.

Proposed Experiments With X-rays and Radium.

By Edward P. Thompson.

Before the advent of Rontgen rays, Sir John Lubbock, F.R.S proved, by a long series of critical, varied and repeated experiments, that the invisible ultra-violet rays are perceived, in some manner or other, by the insignificant, yet highly interesting ant. For details of the apparatus and experiments see "Ants, Bees and Wasps," D. Appleton & Co., published in 1888. His experiments were based upon the dislike which ants, in their nests, have for light. Although they have no such feeling when out in search of food, yet if light is admitted to their nest they at once hurry about in search of dark corners, where they all congregate. If, for example, he uncovered one of the nests, and then placed an opaque substance over one portion, the ants invariably made the shaded portion their rendezvous. The ants likewise carried their pupæ and larvæ to the darkest portions of the nest. This characteristic was also a basis of operations.

His first experiments related to the ants' relative avoidance of visible light rays of different colors. In all these tests the violet and purple rays affected the ants much more strongly than the other colors employed. In a general sense the transmitted light of differently colored glasses appeared to act on ants in the same general order as it does on a photographic plate. Furthermore, they preferred the violet glass to the plain colorless glasses. In place of the latter solutions were tried, and tests involving equal temperatures were included, but the results remained the same. It is needless to say that Sir John Lubbock took every possible precaution and followed the strictest rules of scientific research.

Another series of experiments included ultra-violet rays, negatively. He had found that if the ants have to choose between the violet and other colored glasses, they always preferred one of the latter. Next he found that the effect of putting over the violet glass a layer either of sulphate of quinine or bisulphide of carbon (both of which are transparent to our eyes, but both of which cut off the ultra-violet rays), the effect was to make the violet glass seem to the ants as good a shelter as any of the other colors. Hence, this two-fold result is strong evidence that ants perceive ultra-violet rays.

He then tried more positive experiments with a saturated solution of chrome alum and chromium chloride, as these are very opaque to the visible light rays, but transmit the ultra-violet rays. The results were very striking. It made that portion of their nest so dark that he could see nothing. By an apparent expedient for watching their movements, he found that the ants avoided the ultra-violet rays. Different species of ants and different ants of the same species but of different nests behaved in a similar manner.

Whether the ants actually see some new color or light, or feel or hear it is not certainly known; but that ants constitute a detector of the invisible portion of the spectrum beyond the violet appears conclusive to Sir John Lubbock.

I have no longer the facilities for making X-ray experiments, nor do I know if others have tested their effect upon ants; but I propose to the Carnegie Institution at Washington or to others who are experimenting in the field of ether vibrations or limits of vision in animals, to determine if ants are affected by X-rays.

The electrical engineer is not so much concerned about the physiology of ants as is the naturalist, but he is anxious to add more facts for assisting in arriving at a more exact knowledge of the nature of X-rays. So far, it is known that this form of radiant energy causes certain salts to fluoresce; and that it affects the photographic plate. Consequently, it is like the short wave length from a luminous source. It is at the same time, invisible to man, and is thus like either the very short or very long wave length. It is like a long wave length in its power of penetrating substances which are opaque to light. As the same wave could not be both long and short at the same time, there is no reason why it could not be a mixture of long and short waves or else some energy without waves. Until ants are experimented upon, therefore, there is a void in this department of the science of radiant energy. A short wave, or energy of the spectrum beyond the violet, troubles ants. Will these insects immediately run away from Röntgen rays?

Investigations should also include the recently discovered etheric radiations. As nine years have elapsed since Prof. Röntgen made his remarkable discovery, and although all conceivable tests have been made upon radiant energy, may we not perhaps say, "Go to the ant thou sluggard, consider her ways and be wise?"

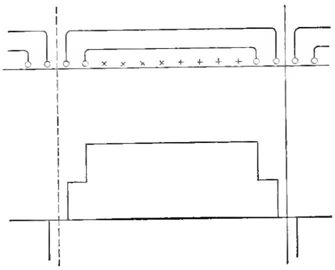
Calculation of the Equivalent Ampere-Turns of Windings for Single and Polyphase Currents.—II.

By C. F. Guilbert.

EQUIVALENT M.M.F. OF A SEPARATE PHASE WINDING.

CONSIDER first the common case of a polyphase winding where all sorts of the same phase are situated, for each pole, one following the other. It is evident that from the standpoint of the distribution of the inductive m.m.f. in the air-gap, the direction of current in the different conductors of each slot is only of interest; we can then group, by imaginary exterior connections, the conductors of different slots of the same phase in such a manner as to constitute a certain number of elementary coils per pole and per phase. In the present instance there are two cases depending upon the number of slots per pole and per phase.

Assume first the case of a winding of q phases with an even number, u, of slots per pole and per phase. Fig. 3 indicates that in this case we can form per pole and per phase $u/2$ elementary concentric coils of N/u turns, if N is the number of field conductors per pole and per phase. The m.m.f. distribution curve takes the form shown in Fig. 4. The angle between the axes of two neighboring slots being, for a bipolar machine, $\pi/q\,u$, the widest elementary coil will have the width



FIGS. 3 AND 4.

$$b = \frac{a}{\pi}\left(\frac{q\,u}{\pi} - 2\frac{\pi}{2\,q\,u}\right)$$

which gives for the quantity $\frac{b}{a}\frac{\pi}{2}$, $\frac{b\,\pi}{a\,2} = \frac{\pi}{2} - \frac{\pi}{2\,q\,u}$.

The m.m.f. of this coil is, therefore,

$$f_i' = \frac{4}{\pi^2}\cos\frac{\pi}{2\,q\,u}\,\frac{N}{u}\,I\,\sqrt{2}.$$

For the second coil we will have similarly for b and $\frac{b}{a}\frac{\pi}{2}$, the values

$$\frac{a}{\pi}\left(\pi - \frac{6\,\pi}{2\,q\,u}\right) \text{ and } \frac{\pi}{2} - \frac{3\,\pi}{2\,q\,u},$$

which lead, for this coil, to an equivalent m.m.f.,

$$f_i'' = \frac{4}{\pi^2}\cos\frac{3\,\pi}{2\,q\,u}\,\frac{N}{u}\,I\,\sqrt{2}$$

and so on. Finally, the equivalent m.m.f. per pole and phase is $\mathfrak{F}_i = f_i' + f_i'' + f_i''' + \ldots$

$$= \frac{2}{\pi^2}\,\frac{\sin\frac{\pi}{2\,q}}{u\,\sin\frac{\pi}{2 q\,u}}\,N\,I\,\sqrt{2}.$$

To obtain the equivalent m.m.f. for q phases, it is merely necessary to multiply the above by q, which finally gives for the equivalent m.m.f. per pole of a width carrying current I,

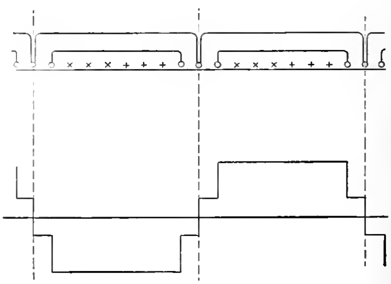
$$\mathfrak{F}_t = q\,\frac{2}{\pi^2}\,\frac{\sin\frac{\pi}{2\,q}}{u\,\sin\frac{\pi}{2\,q u}}\,N\,I\,\sqrt{2}.$$

Suppose, now, that u is an odd number. With $u - 1$ slots we can first form per pole $\frac{u-1}{2}$ elementary coils of $\frac{N}{u}$ turns, and then divide the last slot into two parts so as to form with the slots not utilized a coil of only $\frac{N}{2\,u}$ turns per pole. Figs. 5 and 6 represent diagrammatically the case for a three-phase alternator with three slots per pole and per phase.

The coil of $\frac{N}{2\,u}$ turns will have a width b' equal to the step, so that the equivalent m.m.f. will be $f_i' = \frac{4}{\pi^2}\,\frac{N}{2\,u}\,I\,\sqrt{2}$. The widest coil with $\frac{N}{u}$ turns will have a width

$$b = \frac{a}{\pi}\left(\pi - 2\frac{\pi}{q\,u}\right)$$

since the angular distance between two slots referred to a bipolar



FIGS. 5 AND 6.

machine is $\frac{\pi}{2\,u}$. We then have $\frac{b}{a}\frac{\pi}{2} = \frac{\pi}{2} - \frac{2\,\pi}{2\,q\,u}$, and consequently the equivalent m.m.f. of this coil is

$$f_i'' = \frac{4}{\pi^2}\cos\frac{\pi}{q\,u}\,N\,I\,\sqrt{2}.$$

The narrowest coil, that of the order $\frac{u-1}{2}$ among the coils of $\frac{N}{u}$ turns, will, by analogy, have an equivalent m.m.f. equal to

$$\frac{4}{\pi^2}\cos\left(\frac{u-1}{2}\,\frac{\pi}{q\,u}\right)N\,I\,\sqrt{2}.$$

Summing up, as before, we have for a complete winding, per pole,

$$\mathfrak{F}_i' = q \frac{2}{\pi^2} \frac{\sin \frac{\pi}{2q}}{u \sin \frac{\pi}{2qu}} N I \sqrt{2},$$

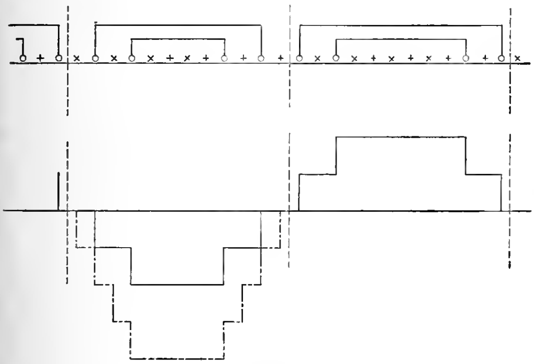
which is identical with the expression when u is an even number.

EQUIVALENT M.M.F. OF A SUPERPOSED PHASE WINDING.

We will now take up the case of superposed phase windings. This superposition can be regarded in two ways: First, that each slot contains only conductors of the same phase, in which case the slots of one phase are alternated with those of another phase; or that each slot contains an equal number of conductors of different phases. We will take up first windings with distinct slots.

Two cases are to be considered according as the number, u, of slots per pole and per phase are even or odd in number. Take first the case of an even number. As in the analogous case considered above, we can group the u slots of one phase and pole in two series of $\frac{u}{2}$ in such a manner as to constitute with a non-neighboring series and with the aid of imaginary connectors, one coil per pole formed of $\frac{u}{2}$ elementary coils placed concentrically (Fig. 7).

If we represent the m.m.f. due to a given current passing through



FIGS. 7 AND 8.

all the conductors of the phase considered, we obtain the distribution shown in Fig. 8. As will be seen, the m.m.f. of a phase is not the same for two neighboring poles. It is thus necessary in order to obtain the mean distribution of the m.m.f. per pole to take the arithmetical sum of the distribution curves under two neighboring poles and to divide the ordinates by 2, which is equivalent to using a double scale.

This summation having been made for the left side of the figure, it is easily seen that the result is as if there were per pole, in the phase considered, twice the number of slots, each of them being the seat of half the number of ampere-conductors. The value of the widths, b, of the elementary coils of a phase of a single pole are then, the angular distance between the two slots being $\frac{\pi}{2qu}$,

$$\frac{a}{\pi}\left(\pi - \frac{\pi}{qu}\right),\ \frac{o}{\pi}\left(\pi - \frac{\pi}{qu}\right)\ \cdots \cdots \frac{a}{\pi}\left(\pi - (2u-1)\frac{\pi}{qu}\right)$$

We then deduce for the successive values of the quantity $\frac{b}{a}\frac{\pi}{2}$.

$$\frac{\pi}{2} - \frac{\pi}{2qu},\quad \frac{\pi}{2} - \frac{3\pi}{2qu},\ \cdots \cdots\ \frac{\pi}{2} - (2u-1)\frac{\pi}{2qu}.$$

If we always designate by N the number of conductors per pole and per phase, the number of turns of each elementary coil will here be $\frac{N}{2u}$, and the equivalent m.m.f. per pole will have for the phase considered,

$$\mathfrak{F}_i = \frac{4}{\pi^2} \frac{N}{2u} I \sqrt{2} \times$$

$$\left[\cos\frac{\pi}{2qu} + \cos\frac{3\pi}{2qu} + \cdots \cos(2u-1)\frac{\pi}{2qu}\right]$$

This sum has for value in applying the method used previously,

$$\mathfrak{F}_i = \frac{2}{\pi^2} \frac{\cos\left[\frac{\pi}{2qu} + (u-1)\frac{\pi}{2qu}\right] \sin u \frac{\pi}{2qu}}{\sin\frac{\pi}{2qu}} \cdot \frac{N I \sqrt{2}}{u} =$$

$$= \frac{2}{\pi^2} \frac{\sin\frac{\pi}{q}}{2u \sin\frac{\pi}{2qu}} N I \sqrt{2}.$$

Finally, we will have for the equivalent m.m.f. corresponding to q phases,

$$\mathfrak{F}i = q \frac{2}{\pi^2} \frac{\sin\frac{\pi}{q}}{2u\sin\frac{\pi}{2qu}} N I \sqrt{2}.$$

It is not without interest to compare the preceding formula with that which we established above for the case of windings by distinct phases. It will be seen that the expression for $\mathfrak{F}_i$ differs only by the factors

$$\frac{\sin\frac{\pi}{2q}}{u\sin\frac{\pi}{2qu}} \text{ and } \frac{\sin\frac{\pi}{q}}{2u\sin\frac{\pi}{2qu}}.$$

These factors have the same value only when the number of phases is very great; that is to say, when the values $\frac{\pi}{q}$ and $\frac{\pi}{qu}$ are such that the sines can be replaced by arcs, when the expressions become equal to unity. In order to make a comparison with the normal values of q, suppose the number of slots is sufficiently large per pole and per phase that the sine can be replaced by the corresponding arc. We have then for the two factors,

$$\frac{\sin\frac{\pi}{2q}}{\frac{\pi}{2q}} \text{ and } \frac{\sin\frac{\pi}{q}}{\frac{\pi}{q}}, \text{ or } \frac{q}{\pi}\, 2\sin\frac{\pi}{2q} \text{ and } \frac{q}{\pi}\sin\frac{\pi}{q}.$$

If we consider in particular the case of a three-phase winding $q = 3$ and the values are, for a factor $\frac{3}{\pi}$, $2 \sin\frac{\pi}{6}$ and $\sin\frac{\pi}{3}$, or 1 and 0.866.

The employment of a superposed phase winding thus reduces the equivalent m.m.f. and consequently the field due to the corresponding winding, by 13 per cent. Superposed phase windings, which have been employed to obtain a distribution as close as possible to that of the sinusoid, thus lead in reality to a reduction of torque, and this is confirmed in practice.

On Turbo-Dynamos.—I.

BY PROF. DR. F. NIETHAMMER.

THE purpose of this paper is to outline the electrical and mechanical difficulties which arise in the design of turbo-dynamos (dynamo-electric generators directly connected to steam turbines) of 500 to 4,000 r.p.m. With all extra high-speed dynamos it is an easy problem to get a high-efficiency, a low-voltage drop, and, in the case of polyphase alternators, assure parallel running even with very variable loads consisting of synchronous motors or rotaries. The weight per kilowatt, the floor space per kilowatt (especially for types with vertical shaft), and the price per kilowatt may, without any difficulty, be kept pretty low, though by no means decreasing inversely proportional to the speed, since with high speeds the materials must be very carefully selected, while the shop work calls for special precision, involving increased labor cost.

The main difficulties in the design of turbo-dynamos are as follows:

(1) Satisfactory commutation to secure non-sparking in direct-current machines.

(2) Excessive heating, as the losses grow with the speed faster than the capability of radiating heat.

(3) High mechanical stress from centrifugal forces on rotating parts, their windings and insulation.

(4) Noiseless running.

It is certainly hazardous to guarantee the same degree of safety in service for turbo-dynamos as for the usual slow-speed, direct-connected dynamos. Any reduction of the speed of steam turbines to about half the value of present practice would be greatly welcomed by the electrical engineer, and the Curtis turbine seems to be a step in this direction. The difference in price would be trifling, as the materials would be cheaper and the wages lower for machines of larger size. A further trouble with these high speeds sometimes arises in three-phase plants of low periodicities. It is a well-known fact that turbo-alternators of 60 cycles can only be built for 3,600, 1,800, 1,200, 900, 600 and 500 r.p.m., and types of 25 periods only for 1,500, 750 and 500 r.p.m.; and in some cases the steam turbine has, therefore, necessitated quite abnormal periodicities. Turbo-alternators for less than 500 kw are rarely manufactured commercially, as they are impossible for small periodicities, neglecting the Laval turbine, since it works with a reduction gear.

In my opinion the rotating steam engine with rotating piston, instead of with reciprocating motion, is much more favorable for electrical work than the steam turbine. I have the following data on rotating steam engines of the Paschke system, which are built from 1 hp up to 10,000 hp and more:

5,000 hp, 250 to 420 r.p.m., as against 750 revolutions of the steam turbine: 4.3 kg. steam consumption for an indicated hp-hour. For 500 hp the speed is 250 to 610, against 1,500 to 2,500 for the steam turbine. It is, of course, necessary to gather further experience concerning this type in regular service.

There is an English patent, No. 6734 (1902) granted to Parsons, which tries to obviate the impossibility mentioned of building an alternator for 25 cycles directly connected to a steam turbine of 3,000 revolutions; but it is rather complicated and consists of two alternators, one of which has a rotating field directly connected to the steam turbine and outside of it an armature rotating with half the speed. This armature drives the field of the second alternator, the armature of which stands still.

(1) The difficulty of commutation for high-speed, direct-current machines is well known and has been discussed at much length. The fact is that some of the best-known electric concerns refuse to manufacture direct-connected, continuous-current turbo-dynamos. A more general use of steam turbines would thus lead to the exclusive adoption of a distribution system with polyphase central stations and sub-stations with rotaries. The excellent uniformity of speed of steam turbines would warrant in any case a very satisfactory service with rotaries even of 40 to 60 cycles.

Sparkless commutation is bound by the fundamental condition that the reactance voltage[1]

$$e_r = 4\, n\, L\, I$$

(where n = periodicity of commutation, L = coefficient of self-induction in henries, I = current in an armature circuit) shall be smaller than 2 to 3 volts at any load, or that the reactance voltage be continuously neutralized by a counter e.m.f. induced by an exterior field (field of commutation), either entirely or at least up to 2 or 3 volts. The high speeds naturally lead to a high value of

$$n = \frac{\textit{velocity of commutator}}{\textit{2 times thickness of a brush}}$$

and on account of the low voltage usually to a high value of the current, I, per armature circuit. Actual calculations on turbo-dyna-

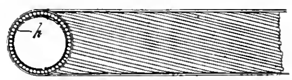


FIG. 1.—PARSONS TWISTED TUBULAR CONDUCTORS.

mos of the best feasible design show reactance voltages of 5 to 15 volts. Without the help of an auxiliary commutation field, e_a, a sparkless commutation seems, therefore, to be next to impossible. A direct reduction of the reactance voltage can only be achieved by decreasing the coefficient of self-induction and the current, I, in an armature circuit. The first condition involves very narrow armature cores, large diameters and extremely high circumferential velocities; the second condition may be satisfied by splitting the type into several machines with proportionally reduced output, all on one shaft and connected in parallel. Somewhat less efficient is the method

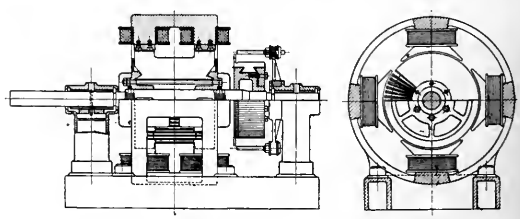

FIG. 2.—SCHÜTTDORFER METHOD OF BUILDING UP ARMATURE CORE.

of using one machine with several separate commutators. A low coefficient of self-induction is equivalent to a high resistance of the self-induced magnetic field round the short-circuited armature coils. Parsons proposes in his English patent, No. 5374, specially shaped, twisted tubular conductors on a smooth armature core (Fig. 1), to increase the magnetic resistance. For the same purpose the Schüttdorfer Maschinenfabrik builds up the armature core of iron sheets split in a radial direction not vertical to the shaft (Fig. 2).

The arrangement for neutralizing the reactance voltage, e_r, by an auxiliary counter e.m.f., e_a, are the following:

(a) *Automatic brush shifting.*

α corresponding to the variable current (Thury, Parsons),

β corresponding to the potential difference between the back (trailing) corner of the brushes and the commutator segments, (Fig. 3, Siemens Bros. English patent, No. 3777, 1903); in both cases the shifting is by a relay and an auxiliary motor.

(b) *Variable stray fields.*—Near the short-circuited armature

[1] Many of the points I can only mention here are more fully treated in the author's work, *Elektrische Machinen, Apparate und Anlagen (Enke).*

coils between the pole tips, small auxiliary poles without winding are arranged, which divert a certain stray field from the main poles to the short-circuited coils. This stray field strength is varied according to the load by shifting these auxiliary poles in a radial or circumferential direction.

(c) *Auxiliary distributed field windings* shifted against the usual field winding by about half a pole pitch and excited by the main current (Ryan, Déri). This arrangement compensates also the armature reaction and allows the voltage to be reduced down to zero without sparking. Fig. 4 shows the cut of a direct-current turbo-dynamo with Déri winding built by the Austrian Union Company (330 kw, 650 volts, 3,000 revolutions; armature diameter = 520 mm., commutator diameter = 300 mm., air gap = 5 mm.). The compensating winding is imbedded into slots; opposite to the short-circuited arma-

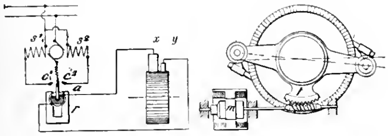

FIG. 3.—SIEMENS BRUSH AND SEGMENT ARRANGEMENT.

ture coils a specially broad commutation tooth directs the necessary commutation field on said coils.

(d) *Auxiliary poles excited by the main current* opposite to the short-circuited armature coils, either as a single-pole (Sautter, Harlé & Cie, Paris) or a two-pole (Siemens & Halske) arrangement.

(e) *Auxiliary Armature Windings.*—Between the main armature winding and the commutator a commutation winding is arranged which is either shifted towards the pole tips (Sayers) or induced by a special small field frame excited by the main current (Seidener); in each case the induced e.m.f. must act against the reactance voltage.

(f) *Spark-extinguishing blow-out devices,* acting either by compressed air (Thury) or by condensers switched between the commutator segments (Thury, German patent, No. 142,562).

(g) *Replacement of the commutator type* by the *unipolar* or *homopolar* machine, in which direct current is produced without any commutation. The main trouble is the fact that all existing unipolar types generate only very low voltages (50 volts and less) and that large eddy currents often occur. By using the most recent materials of exceptionally high mechanical resistivity, like nickel-steel, more satisfactory results may be expected.

(2) The *temperature rise, T,* in degrees Centigrade of a body

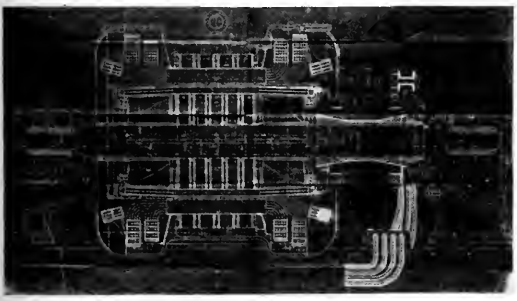

FIG. 4.—DIRECT-CURRENT TURBO-DYNAMO.

rotating at v meters per second and in which W watts are transformed into heat is approximately either

$$T = k \frac{W}{S\ (1 + 0.1\ v)}$$

or

$$T = k' \frac{W}{S\ (1 + 0.3 \sqrt{v})}$$

where S = radiating surface in square centimeters and k and k' are constant.

If the speed of a given type is increased from v to $m\,v$, the voltage rises from e to e_1 volts. If the main current, I, remains the same for both speeds, the copper losses, W_c do not vary for both cases, but the iron losses, $W_h + W_e$ (hysteresis + eddy currents) grow to the value

$$m\,W_h + m^2 W_e.$$

The ratio of the temperature rise T_m (with $m\,v$) to T (with v) is, therefore, using the $\sqrt{v}$ formula, the best for wide variations of speed:

$$T_m : T = \frac{W_c + m\ W_h + m^2 W_e}{1 + 0.3\ \sqrt{m}\ \sqrt{v}} : \frac{W_c + W_h + W_e}{1 + 0.3\ \sqrt{v}}$$

This equation proves that with increasing values of m, that is with increasing speed or circumferential velocity, the temperature rise grows more and more and for a fixed maximum value of T_m there exists a certain speed, $m\,v$, for which W_c must be zero. That means for said high speed, $m\,v$, the machine cannot radiate any copper

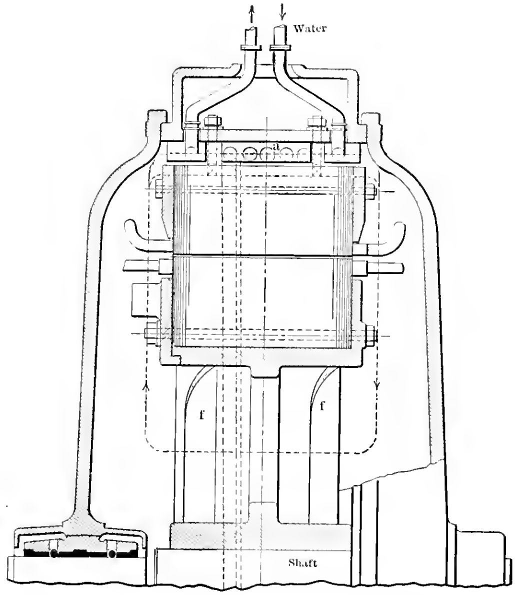

FIG. 5.—GENERATOR FRAME, WITH WATER-COOLING COILS.

losses, or the iron losses heat it to the very limit. In this case the dynamo delivers no useful work at all.

For high speeds especially nothing like an approximate proportionality between output and speed exists, which may be directly seen from the simple expression

$$T = \frac{k_1 + k_2 v + k_3 v^2}{S\ (1 + 0.3\ \sqrt{v})}$$

in which the total losses, W, are replaced by the sum of the copper losses, k_1, the hysteresis, $k_2 v$, and the eddy current, $k_3 v^2$, k_1, k_2 and k_3 being constants. Even in good design of low and moderate speed dynamos, $k_2 v + k_3 v^2$ is equal or larger than k_1, so much the more for high-speed machines, even of the very best design, the iron losses prove to be larger than the copper losses; that means, $k_1 + k_2 v + k_3 v^2$ grows faster with v than the denominator, $S\ (1 + 0.3\ \sqrt{v})$.

To keep the temperature rise sufficiently low, the iron section of turbo-dynamos in the induced parts must, therefore, be chosen as large as possible, and even especially thin iron sheets may be recommended in certain cases. In direct-current generators the radial iron depth is, however, very limited, as the outside diameter has to be small with regard to the high circumferential speed, and the inside diameter is fixed by the dimensions of the shaft. In the usual alternator design with rotating field, any radial iron depth is possible, but there are several drawbacks. The air-gaps diameters being pretty small, the magnetic paths in the induced part become very unequal and the outside strips of the deep sheets grow more and more useless. Besides, the reduction of the iron losses is not proportional to the radial depth, but only about to the square root of it. The result of this reasoning is that the iron sections can usually only be made large enough by increasing the length of the machine. The capability of radiating heat, which decreases with growing speeds, must be artificially ameliorated by a great number of air ducts, in many cases ducts of 15 to 20 mm. breadth on an armature length of only 20 to 50 mm. The output coefficient $k = \frac{kw}{d^2 l\, n}$ (where d = air-gap diameter, l = axial length, n = r.p.m.) must be smaller than with slow-speed types in order to provide for sufficient radiating surface. Wing-shaped blades or even entire fans must often be attached to the rotating parts, diminishing somewhat the efficiency. A very rational means to reduce the dimensions, and especially also the high circumferential speeds, is in the use of water-cooling coils, *a*, wound into the generator frame (Fig. 5), while the air circulates round all the active parts moved by screw-shaped blades, *f*. In a more radical design (German patent, 96,532, by Schuckert) the cooling coils pass directly through the sheet iron of the induced parts.

A disagreeable addition of heating is very often experienced in high-speed generators by unforeseen eddy currents in the armature conductors, in hubs, flanges, bolts and pole shoes.

(3) High speeds necessitate also high circumferential velocities, v_p, of the journals in the bearings, viz., v_p = 10 to 15 meters per second, against 2 to 5 meters in usual designs. For a journal of the dimensions $d_r \times l_p$, the temperature rise is

$$T_p = C \cdot \frac{d_p\ l_p\ v_p^{\ 3/2}}{\pi\ d_p\ l_p} = k^1\, v_p^{\ 3/2}$$

T_p grows with the 3/2 power of v_p. This is the reason why most bearings of turbo-dynamos need artificial lubrication by oil under pressure or circulating water. All high-speed shafts must run absolutely true; the rotating field or armature must be carefully balanced, all the singular parts separately and totally, without and with windings. To avoid dangerous magnetic pulls, even in so-called compensated types (Ryan, Deri) the air-gap must be pretty large and the air-gap induction of moderate size.

Measurement of Internal Resistance of a Battery by Ohm's Method.

By J. L. Dickson.

An interesting method of measuring the internal resistance of a closed-circuit battery is given below.

In Fig. 1, let G represent a galvanometer, R a variable resistance, K a switch for breaking the circuit, C a commutator for reversing the current by means of the plug P, and B a battery, the internal resistance of which is to be measured.

The apparatus is to be connected up in series as shown in the

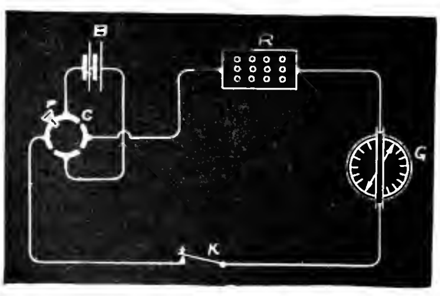

FIG. 1.—DIAGRAM OF CIRCUITS.

diagram, using short, heavy lead wires of negligible resistance for the connections. The plane of the galvanometer coils should be carefully set in the magnetic meridian, and the resistance of the galvanometer, if not known, determined by the Wheatstone bridge method.

The resistance R is then so adjusted as to give an angle of deflection of about 40° on the galvanometer G. This deflection is to be recorded, then the current reversed through the galvanometer by means of the commutator C, and the deflection again noted. In reading the angle of deflection of the galvanometer both ends of the needle are to be read; the current is then reversed and both ends again read, and the average of all four readings taken as the angle of deflection. Enough more of the resistance R is then inserted to

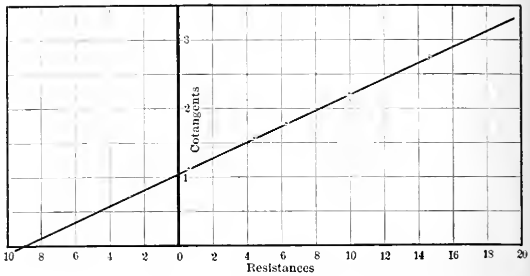

FIG. 2.—CURVES SHOWING RELATION BETWEEN RESISTANCES AND COTANGENTS.

reduce the deflections by about 5° and the readings again taken as above. This is to be continued until the deflections are reduced to 20° or less.

Let us assume that during a certain test the following readings were obtained:

Resistance, Galvanom.	Resistance, Circuit.	Total Resistance.	Angle of Deflection. Position 1.	Position 2.	Position 3.	Position 4.	True Deflec.	Cotan. Deflec.
Ohm.	Ohm.	Ohm.	Deg.	Deg.	Deg.	Deg.		
.65	0.0	.65	40	39	43	43	41	1.15
.65	3.7	4.35	32	31	32	34	32	1.60
.65	5.7	6.35	29	28	30	31	29	1.80
.65	9.4	10.05	24	25	24	24	24	2.24
.65	13.9	14.55	20	19	20	19	20	2.74
.65	20.9	21.55	15	16	16	15	15	3.73

From the above readings let us plot a curve, using known resistance in circuit (adjustable resistance plus galvanometer resistance) as abscissæ and the reciprocals of the tangents of the angle of deflection as ordinates. The origin should represent zero values of both quantities.

The curve is found to be a straight line and shows that the resistances and cotangents of the angle of deflection bear a certain relation to one another; that is, as the resistances increase, so do the cotangents of the angles. This curve is continued as shown until it cuts the axis of abscissas, and the intercept on this axis represents the internal resistance of the battery, which in this case is found to be 8.9 ohms.

The interception of the straight line on the horizontal axis gives the internal resistance, because the external resistances were plotted on the other side of the zero point. Therefore, if this line is continued, it passes back of the zero, which is on the internal resistance side of the horizontal axis.

This method assumes a constant e.m.f. for the battery, and is not suitable for cells which polarize.

Electricity in Syria.

A recent United States consular report received at Washington from Syria says: "Recently the Beirut Gas Works, which has a ninety-nine year exclusive franchise from the Ottoman Government and first option on use of electricity, was purchased by Ibrahim Sabbag, a wealthy and enterprising Syrian, who is an honorary dragoman of this consulate. Mr. Sabbag is interested in securing the co-operation of American experts, being hopeful of extending the use of gas and eventually of electricity throughout Turkey in Asia. American electric fans have recently been admitted to Beirut, where quite a few have been sold during the past year. It is believed that electric street railways will be authorized by the Central Government before long, along with electric light, telephones, etc."

Standardizing of Subway Manhole Construction.

By HUGH C. BAKER, JR.

ENGINEERS who have had experience in the construction of subways for telephone or electric light cables, especially in suburban districts, will readily appreciate the value of a system of manhole construction whereby all manholes can be built exactly the same in size and shape, with interchangeable concrete wall and top blocks which are placed together by ordinary laborers practically without supervision.

Such a system has now been designed and patented, and was used last year experimentally by the New York Telephone Company.

In Fig. 1 is shown a sectional elevation of a concrete block manhole which is believed to have points of sufficient merit to make it a standard. The walls of the manhole are built up of separate horizontal layers or rings of concrete blocks of two different sizes and shapes—eight blocks to a ring, laid on a six-inch foundation of concrete. The four end wall blocks, exactly similar in size and shape, are adapted to be reversed or turned end for end in each separate layer so that all joints are broken, or staggered, as shown by the sectional elevation.

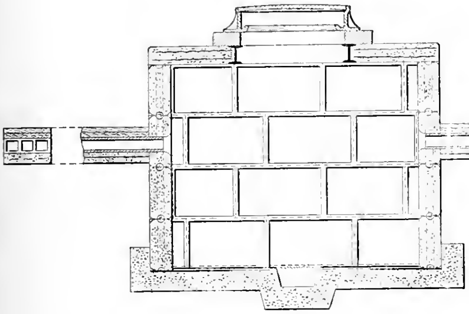

FIG. 1.—SECTIONAL ELEVATION OF MANHOLE.

The blocks can be made any suitable height. In moulding, grooves are formed in the flat surfaces of the blocks (Figs. 1 and 4) preferably semi-circular in cross-section, as shown in Fig. 5. When the walls of the manhole are constructed, these grooves, coming together, form continuous open spaces, extending from top to bottom of the manhole, which are filled with liquid cementing material, forming mortar dowels between each block horizontally and vertically, as shown by Fig. 1. These dowels not only tend to lock the blocks in position, but will prevent water from passing through the joints.

FIG. 2.—GENERAL VIEW OF BLOCK MANHOLE.

The roof of the manhole is formed by sliding into position six flat concrete slabs, each about 5 inches thick, reinforced with expanded metal, or steel rods, and with beveled edges. The slabs bear on the flanges of the steel beams and on the walls. On completion, all exposed joints in the walls and roof are pointed with mortar, and the inside of the manhole is finished with a white cement wash to increase the light. The manhole illustrated, if properly constructed, should be absolutely impervious to water or gas.

The advantages of the block concrete manhole, compared to any previous method of construction, including monolithic concrete and brick construction, are that the blocks can be made in one place under proper supervision, in the winter time if necessary, shipped to the work, and laid up without skilled labor; and that there is very little, if any, waste of material. The duct entrance is made by breaking away portions of the blocks and filling in the opening around the ducts with concrete, using a small inside mould and outside boards to confine the free concrete to the shape of the walls.

Last year the New York Telephone Company constructed a large amount of subway in its suburban territory adjacent to New York City. More than one hundred sets of the concrete tops, about the same as illustrated in Figs. 1 and 3, were used on the ordinary brick manholes with satisfactory results, and a number of the concrete block manholes were constructed, the blocks being without grooves and rectangular in cross section.

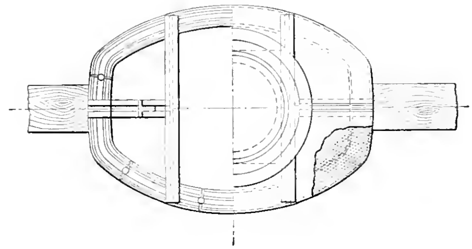

FIG. 3.—PLAN OF MANHOLE.

Fig. 2 illustrates one of the standard block manholes actually built in Rye, N. Y., where a railway bridge crossing was made with creosoted wooden conduit. All of the blocks were made in a large barn in Rye and shipped by wagon or rail to the different places where they were to be used. Over 1,200 blocks were made in the barn and only nine were broken in handling.

Portland cement concrete was used mixed in the proportion of 1-2-4, using three-quarter-inch machine-crushed trap-rock from the Connecticut quarries. The blocks were made in separate wooden molds and about five hours after mixing were placed in the open air to set from three to five days, before shipping. The average cost of the block manholes constructed was found to be less than the cost of brick manholes of the same size and shape, and it was found that a block manhole could be constructed in about one-third of the time required to build a brick manhole. A concrete block manhole can be constructed, the iron cover set, the excavation filled in and the street opened for traffic in five hours by three men, under favorable conditions, whereas it usually takes a mason and helper with from three to four laborers one and one-half days to build a brick manhole of the same size.

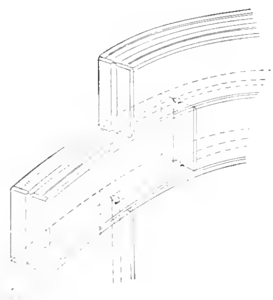

FIG. 4.—PART OF WALL SHOWING GROOVES.

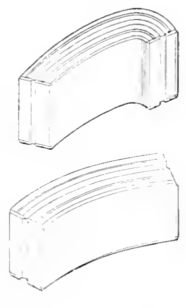

FIG. 4A.—WALL BLOCK SHOWING GROOVES.

The concrete blocks used last year were unnecessarily large and heavy, and time was lost in moulding in separate moulds. A new form of mould has been designed, by means of which the required number of blocks for an entire manhole can be made in a small space in one operation, thereby greatly reducing the cost of manufacture.

The use of the block manholes in city streets is not always practicable, because of the presence of pipes and other obstructions. Under such conditions it is necessary to design each separate manhole to conform to the space available; and although a monolithic concrete manhole might be built instead of brick, it is less expensive to use brick, because of the high cost of building suitable interior moulds which are required in the construction of the monolithic concrete manholes.

For suburban work or the construction of long line subways on country roads, the concrete block manhole is without doubt the most economical and most suitable form of construction yet devised, and it is believed that a large number will be used in the immediate future.

A manhole has been designed built up of semi-hollow blocks which will probably be experimented with this year. The blocks when placed in the walls form vertical spaces through the walls similar to the construction of some of the concrete buildings which are now being erected in the Southern and Western States. It is not believed that the hollow blocks will be as universally suitable as the solid grooved blocks for manhole construction, however, because of the difficulty in making water-tight and gas-tight joints. The only object in using hollow, or semi-hollow, blocks would be to reduce the weight and the amount of concrete required.

Early References to the Mariner's Compass.

The following are the passages referred to by Brother Potamian in his introductory notice to the letter of Petrus Peregrinus on the magnet, which we printed last week:

Abbot Neckam (1157-1217) in his *De Naturis Rerum,* writes:

The sailors, moreover, as they sail over the sea, when in cloudy weather they can no longer profit by the light of the sun, or when the world is wrapped up in the darkness of the shades of night and they are ignorant to what point their ship's course is directed, these mariners touch the lodestone with a needle, which (the needle) is whirled round in a circle until when its motion ceases, its point looks direct to the north. (*Cuspis ipsius septentrionalem plagam respiciat.*)

In his *De Utensilibus,* we read:

Among other stores of a ship there must be a needle mounted on a support (*habeat etiam acum jaculo superpositam*) which will oscillate and turn until the point looks to the north, and the sailors will thus know how to direct their course when the pole star is concealed through the troubled state of the atmosphere."[1]

Alexander Neckam was born at St. Albans in 1157, joined the Augustinian Order and taught in the University of Paris from 1180 to 1187, after which he returned to England to take charge of a College of his Order at Dunstable. He was elected Abbot of Cirencester in 1213 and died at Kemsey, near Worcester, in 1217.

Guyot de Provins' satirical poem, written about 1208, contains the following passage:

The mariners employ an art which cannot deceive,
By the property of the lodestone.
An ugly stone and brown,
To which iron joints itself willingly
They have; they attend to where it points
After they have applied a needle to it:
And they lay the latter on a straw
And put it simply in the water
Where the straw makes it float.
Then the point turns direct
To the star with such certainty
That no man will ever doubt it.
Nor will it ever go wrong.
When the sea is dark and hazy,
That one sees neither star nor moon,
Then they put a light by the needle
And have no fear of losing their way.
The point turns towards the star;
And the mariners are taught
To follow the right way.
It is an art which cannot fail.

Provins, from which Guyot took his surname, was a small town in the vicinity of Paris.

Cardinal Jacques de Vitry, in his *Historia Orientalis,* Cap 89, writes:

"An iron needle, after having been in contact with the lodestone, turns towards the north star, so that it is very necessary for those who navigate the seas."

Jacques de Vitry was born at Argenteuil, near Paris, joined the fourth crusade, became Bishop of Ptolemais, and died in Rome in 1244. He wrote his "Description of Palestine," which forms the first book of his *Historia Orientalis,* in the East, between 1215 and 1220.

Albertus Magnus (1200-1280) in his *De Mineralibus,* Lib. II., Tract. 3, Cap. 6, writes:

"It is the end of the lodestone which makes the iron that touched it turn to the north (*ad zoron*) and which is of use to mariners; but the other end of the needle turns towards the south (*ad aphron*)."

This illustrious Bavarian schoolman joined the Dominican Order in his youth, lectured to great audiences in Cologne, became Bishop of Ratisbonne in 1260, and died in 1280. Thomas Aquinas, the greatest of schoolmen, was among his pupils.

In the Spanish code of laws, begun in 1256, during the reign of Alfonso el Sabio, and known as *Las Siete Partidas,* we read:

"Just as mariners are guided during the night by the needle, which replaces for them the shores and pole star alike, by showing them the course to pursue both in fair weather and foul, so those who are called upon to advise the King must always be guided by a spirit of justice."

Brunetto Latini, in his *Trésor de toutes Choses,* 1260, writes:

"The sailors navigate the seas guided by the two stars called the tramontanes, and each of the two parts of the lodestone directs the end of the needle to the star to which that part itself turns." (The reverse is the case).

Brunetto Latini (1230-1294) was a man of great eminence in the thirteenth century; Dante was among his pupils at Florence. For political reasons, he removed to Paris, where he wrote his *Trésor* and also his *Tesoretto.* He visited Roger Bacon at Oxford about 1260.

In his treatise *De Contemplatione,* begun in 1272, Raymond Lully writes:

"As the needle, after having touched the lodestone, turns to the north, so the mariners' needle (*acus nautica*) directs them over the sea."

Lully was born at Palma in the Island of Majorca in 1236; he joined the Third Order of St. Francis, dying in 1315.

Ristoro d'Arezzo, in his *Libro della Composizione del Mundo,* written in 1282, has the following:

"Besides this, there is the needle which guides the mariner, and which is itself directed by the star called the tramontane."

The following metrical translation of a poem by Guido Guinicelli, an Italian priest, 1276, we take from Bauer's "Principal Facts Relating to the Earth's Magnetism," 1902:

In what strange regions 'neath the polar star
May the great hills of massy lodestone rise,
Virtue imparting to the ambient air
To draw the stubborn iron; while afar
From that same stone, the hidden virtue flies
To turn the quivering needle to the Bear
In splendor blazing in the Northern skies.

The above extracts show that the directive property of the magnetic needle was well known in England, France, Germany, Spain and Italy in the thirteenth century. In the passage from Neckam, the *acum jaculo superpositam* has been construed by some to mean a form of pivoted needle, while in the letter of Peregrinus, 1269, which will appear in our next issue, the double pivoted form is clearly described. In this connection it will be interesting to note that the Dent Brothers, of London, have adopted in some of their ships' compasses this very mode of suspension on account of the damping effect which it exercises on the swing of the magnet.

[1] The Chronicles and Memoirs of Great Britain and Ireland during the Middle Ages, by Thomas Wright (1863).

High-Tension Work.

The March meeting of the American Institute of Electrical Engineers will be devoted to a discussion of subjects relating to high-tension work, which will be introduced by a number of papers serving as a framework for the discussion, to which all members are invited to contribute. Below are given abstracts of these papers:

THE RELATIVE FIRE RISK OF OIL AND AIR-BLAST TRANSFORMERS.

In opening the author, Mr. E. W. Rice, Jr., says that two types of transformers have been extensively used in electrical installations up to date, distinguished by the method of insulation and cooling employed. The "oil transformer" relies upon oil as the cooling and insulating fluid. The "air-blast transformer" contains insulation material mainly of cloth, paper and wood impregnated with oil or varnish, and is cooled by the circulation of a blast of air. In both types the insulating material is of an inflammable nature and under certain abnormal conditions may take fire with more or less serious consequences.

The electrical engineer must, therefore, consider carefully not only the relative but the actual fire hazard which exists, and by proper and common-sense methods minimize such danger. Both types can be made entirely safe by correct methods of design and installation.

It will be admitted that in general that type which contains the greater quantity of inflammable material will occasion the greater fire hazard. The inflammable material in an air-blast transformer of say 1,000-kw capacity will amount to about 800 pounds, in an oil-cooled transformer of the same capacity the amount will be about 7,300 pounds. While this comparison cannot be taken as a measure of the relative fire risk, it is an indication to be considered, especially in view of the fluidity, the low temperature of ignition, and high calorific value of oil.

While the quantity of inflammable material in an air-blast transformer is, as stated, relatively small, it has an extended surface exposed to a large volume of air, and, therefore, if a fire starts from internal causes, such as short-circuit or extreme overload, is capable of rapid combustion. This combustion could be checked by shutting off the flow of air to a transformer by means of a diaphragm automatically closed by the melting of a fusible link, the fusible link so located as to be melted by the first contact with flame; a method similar to that employed for closing fire doors in buildings.

An oil-transformer properly cooled is probably not particularly subject to ignition of the oil from internal burn-outs or arcs. It is well known that oil is an excellent medium for the smothering of alternating arcs, and this principle is utilized in connection with oil switches.

The vapor above the oil may, however, be ignited by electrical discharges. Even in this case, while the quantity of combustible material is enormous, the surface exposed is relatively small. The principal fire hazard in an oil transformer is due to the large mass of inflammable liquid material which, under certain conditions, may become totally consumed. It becomes a special hazard in the case of fire from sources eternal to itself.

Considerations of fire cost, economy of space, simplicity, operating costs, etc., have resulted in placing transformers in the same room with switchboards and other apparatus, such as synchronous converters, motor-generators, etc. Under such conditions it would seem that the air-blast transformer constituted the lesser fire risk than the oil transformer, and would, therefore, be generally employed if the fire risk were the only consideration. The air-blast type, however, is limited in practice to pressures of about 30,000 to 35,000, as the static discharge which occurs at much higher pressures would in time break down the insulation. It is, therefore, necessary to employ oil insulation on the higher pressures now common.

The fire risk can be practically eliminated by placing such transformers in a room or rooms separated by suitable fire walls from the other part of the plant. This plan has already been proposed and introduced. An entirely separate building, subdivided again into suitable rooms, may be employed where the maximum of safety is demanded. Much may be done to limit the risk, even when the transformers are placed in the same room with other apparatus, by proper systems of piping for drainage of the oil away from the building, by placing the transformers in a depressed area of concrete arranged for rapid drainage, etc. Of course, any of the methods commonly employed for preventing, limiting or extinguishing oil fires may be properly employed.

THE USE OF GROUP SWITCHES IN LARGE POWER PLANTS.

Mr. L. B. Stillwell, in a paper with the above title, considers the group-switch system with particular reference to the plant of that system installed at the Manhattan power station in New York. In this plant two complete sets of main bus-bars are used. Switches are provided by means of which each of these sets may be divided into two independent sets of bus-bars to each of which four alternators and four groups of feeders may be connected. Eight group switches are provided, through each of which current is supplied to a set of auxiliary bus-bars, to which in turn the individual feeders are connected through their respective switches. One of the eight feeder groups is used to supply power to auxiliaries in the power house. The other seven groups supply power, respectively, to the seven sub-stations which receive power from this central source. All switches in the high-pressure alternating-current circuits are of the motor-operated oil type.

The arguments in favor of the group switch as used in the plant of the Manhattan Railway Company are as follows:

1. It affords an additional means of opening a feeder switch that fails to open its circuit, when operated for that purpose. The advantages of the group switch in respect to this function to-day appear materially less than they did five years ago, for the reason that the power-operated oil switch within the period named has demonstrated a high degree of reliability. However, it cannot be assumed that the feeder switch is invariably reliable, and, therefore, judgment of the weight of the argument in favor of the group switch, based upon its use as a reserve for the feeder switch, becomes a question of judgment of the chances of failure of the feeder switch on the one hand and the seriousness of total interruption of power supply on the other.

2. It affords means of reducing aggregate load upon the power house in case of necessity, more rapidly and otherwise less objectionably than the usual method of cutting off individual feeders. It will sometimes happen in the operation of a power plant that it becomes necessary suddenly to shut down one of the generating units. If the load carried at the time be such that the shutting down of the generator implies reduction of the external load, this can be accomplished most conveniently by operating one or two group switches.

3. Where duplicate main bus-bars are used it facilitates transfer of load from one set to the other, in case it becomes necessary suddenly in operation to make such transfer. As bus-bars and connections are now installed in our best plants, this necessity does not arise frequently; nevertheless, it is liable to occur, and obviously half a dozen group switches may be used to affect the transfer in much less time than would be required were five or six times that number of individual feeder switches used.

4. The grouping of the external feeder circuits in group units bearing a simple fixed relation to the generator units establishes a symmetry and proportion most useful to the operator, particularly in times of emergency. In the case of the plant under consideration, at times of full load, the power passing through each group switch is substantially equal to the output of one generating unit. This relation of course does not exist under partial loads, but under such loads it is not difficult usually to keep in service generating capacity exceeding the load by a margin sufficient to make it possible to shut down one generator without cutting off feeders; and in cases where this margin of capacity is not kept in service it is, nevertheless, a more speedy and certain operation to cut off the necessary number of groups of feeders than it would be to cut off a proportionate number of individual feeders.

The arguments against the group switch are as follows:

1. It introduces additional apparatus and, therefore, in itself increases the risk of interruption due to failure in switch insulation, etc. The successful operation of many plants, particularly in America, has been interfered with by the introduction of too much switch gear and too many safety devices, automatic and other; these additions in themselves being responsible in some cases for more trouble than they prevent; and it is to be noted that the group switch implies the auxiliary bus-bar. Here again it is impossible to dogmatize, for as the result of additional experience, the judgment of to-day may be reversed five years from now. Mr. Stillwell considers that if the group switch and the auxiliary bus-bars be reasonably well insulated and installed, the interruptions originating in this additional apparatus should be almost negligible in the case of such a plant as that to which his remarks refer.

2. The group switch and its bus-bars imply, of course, an increase of cost of the plant. In case of the Manhattan plant this increase is about 10 per cent. of the cost of the switch gear and measuring apparatus, and about four-tenths of 1 per cent. of the cost of the plant. To put it another way, the cost of the group switches and bus-bars for the plant approximates $20,000, and the annual cost, assuming this to be 10 per cent. of the investment costs is $2,000, which is about two-tenths of 1 per cent. of the annual cost of operating the entire plant, including sub-stations.

In the plants in which the feeder unit equals or exceeds the dynamo unit of power, the group switch, of course, disappears. In this case, however, it may still be advisable to use two feeder switches in series in order to avoid the necessity of shutting down the entire plant in case of the failure of a single feeder switch.

Obviously, also, there is no reason for attempting to use group switches in cases where the total number of feeders is small. For plants comparable in magnitude to the plant of the Manhattan Railway Company, using a very considerable number of feeders, the group switch is important and its use generally advisable.

OIL SWITCHES FOR HIGH PRESSURES.

Mr. E. M. Hewlett, in a paper with the above title, compares the oil-break switch with the air-break switch. The following points are given as the main ones for consideration:

1. *Abnormal Rise in Pressure.*—Owing to the fact that in oil switches the circuit is opened at the zero point of the wave, the rise of pressure found in the air-break switch is not experienced. This point is of particular importance in high-pressure, long-distance lines, and in cables carrying considerable energy.

2. *Capacity.*—Experience has proved that oil switches may be designed to break circuits of practically unlimited capacity.

3. *Length of Arc.*—Owing to the smothering action of the oil on the arc the length of arc under oil is only a fraction of its length in air.

4. *Insulation.*—The insulating qualities of the oil decrease the distance required to prevent leakage and arcing.

5. *Size of Switch.*—Owing to the fact that the arc length is materially decreased and the value of the oil as an insulation reduces the creeping surface, an oil switch can be made very much more compact than an air switch.

6. *Remote Control.*—The design of the oil switch lends itself readily to operation by control from a distance.

7. *Arc Confined.*—The fact that the arc is ruptured under the oil within the switch has two advantages. First, switches can be placed close together without danger of short-circuit; second, in case of emergency, confusion is avoided as there is no visible arc to disconcert the attendant.

8. *Station Arrangement.*—The flexibility of the oil switch places no limitations on the station arrangement, permitting the circuits and busses to be arranged in the most advantageous manner.

9. *Isolation of Phases.*—The possibility of complete isolation of the phases in a reasonable space is easily secured by the use of oil switches.

TERMINALS AND BUSHINGS FOR HIGH-PRESSURE TRANSFORMERS.

Mr. Walter S. Moody, in a paper, considers the subjects of cables, straps, connectors, etc., for both high and low-tension side, designed both for terminal connections and for changes in the ratio of transformation, together with their insulation. In transformers for moderate pressure and having but two high and low-pressure terminals, the problem of terminals is a simple one; with higher pressures and numerous changes in the ratio, however, the design of these parts of the transformer often becomes a most difficult problem upon the proper solution of which depends, to no small extent, the reliability of the transformer.

It is much better to have the high and low-pressure terminals at opposite ends of the structure, for it is almost impossible to keep safe distances between the terminal and connecting coil leads, when all are at one end. In a shell-type structure, having its coils in vertical position, this requires one set of coil terminals to be at the bottom of the case, but to bring these safely to the top is not as difficult as to separate high and low-pressure conductors that are at the same end of the windings.

In an oil-immersed transformer the insulation of coil terminals presents little difficulty, as it is simply necessary to have all leads rigidly spaced a safe distance from each other and from the coils, and covered with sufficient water-proof insulation to prevent any moisture penetrating the coil around the terminals before the oil is put in.

In air-blast transformers, however, the case is different; here all terminals must be covered with an insulation integral with that on the coil itself, to a distance from the coil that provides sufficient surface insulation, even when the lead is well covered with dust and dirt.

Often the dielectric strength of a transformer is materially lowered by allowing the coil terminals or taps to project beyond the sides of the coils, thus shortening the distance between the primary and secondary. "Spreading" the exposed ends of the windings removes this difficulty, except when the terminal comes from a point well within the coil, but introduces a more serious defect, lack of rigidity to withstand the strains of short-circuits. Usually the problem can be solved by so winding coils as to have only outside terminals and locating such coils as have taps on the outside of the coil structure.

The best location for main terminals naturally varies with the type of transformer and its pressure; for the air-blast type, the air chamber forms a convenient and natural location for the low-pressure wiring, and the terminals of these are, therefore, usually located in the base of such transformers and made accessible by doors in the side of the base. For pressures not exceeding 25,000 volts, the high-pressure wiring can also be placed in the air chamber, without making the air chamber of excessive cross-section, so that all transformer terminals are in the base and exposed wiring is avoided. Heavy rubber-insulated cable is to be avoided in such construction, however, for should the rubber take fire from short-circuit or other causes a draft of air will carry the fire along the duct and into the transformers with great rapidity.

In oil-filled transformers the terminals are, of necessity, located at or near the top of the case. Often for convenience in external wiring projecting pockets are provided through which terminal leads may leave the case in a downward direction. With such construction, it is necessary to have a solid section in the cable, just above the oil line, and to have this section uninsulated or covered with an insulation impervious to oil, otherwise the cable and insulation will act as a syphon and discharge oil.

Below 40,000 volts the insulation of high-pressure terminals offers no special difficulty; porcelain or glass bushings can readily be obtained that are safe for this pressure, even if the conductor has no insulating covering. For higher pressures, the problem is more difficult, if no insulation is used on conductor, the bushings become expensive and so large that there is scarcely room on top of a moderate size transformer for as many terminals as are often required.

Some of the more common forms of bushings that have been used are wooden tubes, hard-rubber tubes, glass and porcelain tubes, both single and concentric, and numerous forms of molded porcelain bushings.

Wooden tubes of the necessary size cannot be thoroughly dried and filled. Hard rubber is so apt to contain impurities that it is unsatisfactory; moreover, it deteriorates rapidly if ozone is generated near it. Glass is fragile and must be protected with other semi insulators. Porcelain, or any smooth tube, must be very long if it have sufficient leakage surface to be safe when dirty, and even the best shapes of corrugated bushings are large and expensive when capable of withstanding a test of from 75,000 to 160,000 volts. All things considered, the following practice is quite satisfactory for test pressures not exceeding 160,000:

Insulate the lead with varnished wrappings that will safely withstand for one minute about half of the test pressure to be applied, bringing out this lead through a porcelain bushing having the same strength as the insulation of the lead, and sufficient surface to prevent leakage at this pressure when dirty; in other words, let the insulation of the leads be sufficient for the working pressure, and the porcelain be of such strength as to give the factor of safety desired. This combination forms a far safer insulation than a bare conductor and a larger bushing, which would stand the same puncture test as the combination, from the well-known fact that oxidized linseed oil is an insulation that will momentarily stand several times as much as it will for any considerable length of time, while porcelain, glass, etc., have no such time factor.

In leads requiring a test of 100,000 volts or more, and insulated in this manner, an additional difficulty is met in the induced charge on the outer surface of the insulation; at this pressure the surface is covered with a heavy brush discharge that so reduces the surface resistance to leakage that 100,000 volts will travel along several feet. It is usually impracticable to make the insulated lead long enough to withstand the pressure under these conditions, but the discharge may be broken up, so that it will not appreciably reduce the surface resistance, by bell-shaped pieces of rubber, porcelain or other insulation slipped over the lead before all the varnished wrappings are put on, and having its small end so shaped as to allow of its being burned in the outer wrappings.

In transformers designed for Y-connection and grounded neutral, some transformer builders, in order to save expense on high-pressure bushings, have grounded one terminal on the case and insulated only; such leads as are to be connected to the line; this prevents operation with △ connections, but otherwise seems unobjectionable. In similar manner, the use of three-phase transformers with the interconnecting between the phases made within the case, reduces the expense and possibility of trouble with bushings.

Eighty thousand volts is the highest pressure that is now practicable for transmission work, but transformers and insulators must be tested, consequently there is some demand for transformers working up to 200,000 volts. The insulation of the terminals of such transformers is the most formidable part of their design. As yet there is no satisfactory solution of the problem except to use oil-filled tubes as terminals. A terminal that has withstood 375,000 volts without any indication of weakness is constructed as follows:

The tube was the shape of two truncated cones, bases together; about 12 in. in diameter at the center and 4 in. at either end; it was built up of thin wooden rings, telescoped a short distance into each other and held together by the conductor, which, for mechanical purposes was made quite heavy, and which was located in the axis of the cones and supported by washers at either end of the tube; between each section of the tube were collars of insulating material, some three inches larger in diameter, than the tube which served the purpose of greatly increasing the leakage surface. After the sections were drawn tightly together by nuts at each end of the conductor, the whole structure was repeatedly dipped in varnish and dried, thus sealing all joints. The terminal was mounted with the lower end several inches under the oil in the transformer and with its largest diameter on a level with the cover; the lower end of the tube was tightly sealed, making the tube perfectly oil-tight.

At present we are passing through a period of development in line construction. Each engineer of a new transmission system of considerable length desires to use as high pressure as possible with a line construction of reasonable cost, but few are sure whether 50, 60, 70 or 80,000 volts is the safe maximum for their conditions. It is common, therefore, for the manufacturers to be asked to make transformers that can be operated at several voltages on the high-pressure side. The result, whether accomplished with series-multiple connection, changing from △ to Y, or simply by taps, usually requires so many terminals that it becomes quite impracticable to place all the necessary leads outside of the case, even were it desirable to do so; consequently, accessible terminals inside the case must be provided. Again, at these and lower pressures, also, it is usually desirable to provide for limited range of adjustment in the ratio, say, by 2 per cent., with a total of 10 per cent.; such changes are usually too small to be made except by means of taps on the high-pressure windings.

Except to transformers of very large capacity, there would be no room safely to insulate so numerous terminals above the surface of the oil; the practice is, therefore, to locate such terminals just under the oil and make them as accessible as possible, either by the removal of the transformer top or through an auxiliary cover on the top of the case. It is better that each of these terminals be separately supported by glass or porcelain insulators, for a single support, such as a slab of marble, is almost sure to collect sufficient semi-conducting material to cause trouble sooner or later. Such terminals being, at the best, rather inaccessible there is danger that a wrong or imperfect connection will be made when changes are desired; the following method of mounting transformers in the tank greatly simplifies the problem of getting at such terminals, especially when transformers are installed under a crane. Instead of supporting the transformer proper on the base of the case as usual, it is hung from a strong cover; the interior terminals are placed in about the usual position, but are supported by the bolts carrying the transformer. To get at these terminals it is then simply necessary to raise the cover with the transformer, until the terminals are on a level with the top of the case; connections may then be made with convenience and safety and the transformer returned to its position in the tank.

Usually low-pressure terminals present no special difficulties; when transformers are connected in multiple and deliver 500 amp. or more, special caution should be taken that all joints are soldered or that terminals are of such construction as to have extremely low contact resistances. Taper plugs and receptacles are perhaps the most reliable form of contact for the purpose.

Current in excess of 500 amp. should never be brought out through separate openings in the case, otherwise there will be local heating around the terminal and needless reactance introduced into the circuit. Currents over 2,500 amp. should be brought out by means of intermixed bus-bars for the same reason.

The Ward Leonard Oerlikon Locomotive.

We publish herewith three interesting photographs showing the Ward Leonard Oerlikon locomotive in actual operation. The practical tests of this locomotive began the first week in February, the tests being made in the presence of a Swiss government committee appointed for the purpose of investigating the locomotive. The entire control of the locomotive in starting, accelerating, varying the speed, braking electrically, stopping and reversing was accomplished in the most satisfactory manner by a single controlling hand wheel, which controls the small current required for exciting the field of the generator. The experiments were conducted with a single-phase current of 13,000 volts. As a result of these satisfactory trials the Oerlikon Company arranged to extend its private experimental line

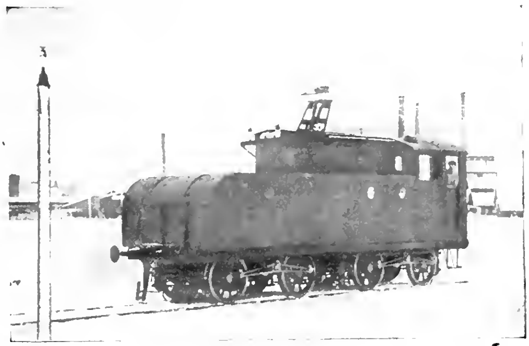

FIG. 1.—GENERAL VIEW OF LOCOMOTIVE.

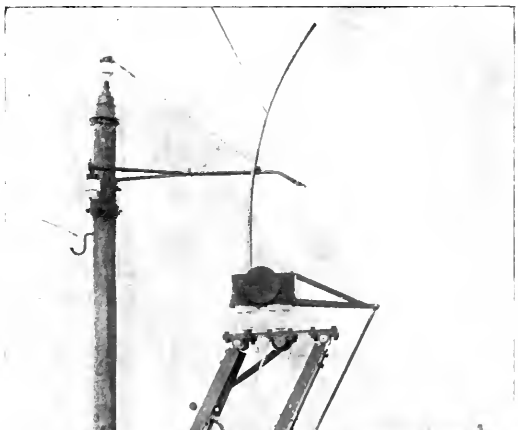

FIG. 2.—CURRENT-COLLECTING DEVICE ON TOP OF CAB.

to the Seebach station, which is one terminus of the State Railway to be equipped with the Ward Leonard system by the Oerlikon Company in connection with the State Railway authorities.

Mr. Leonard has called our attention to a typographical error which occurred in his article published in our issue of February 27. Mr. Leonard had stated that the horse-power of modern steam locomotives had reached 1,750 hp and that two of such locomotives were often used upon a single train, showing that modern practice demands upwards of 3,000 hp upon a single train. This figure of 1,750 hp was by error printed "175 hp." Mr. Leonard believes that the immediate future will see single freight trains operated by upwards of 5,000 hp, and claims that his system presents unique advantages for such heavy service because of the simplicity and perfection of the multiple control of several locomotives, which will divide, under all conditions, the total tractive effort demanded by such a train.

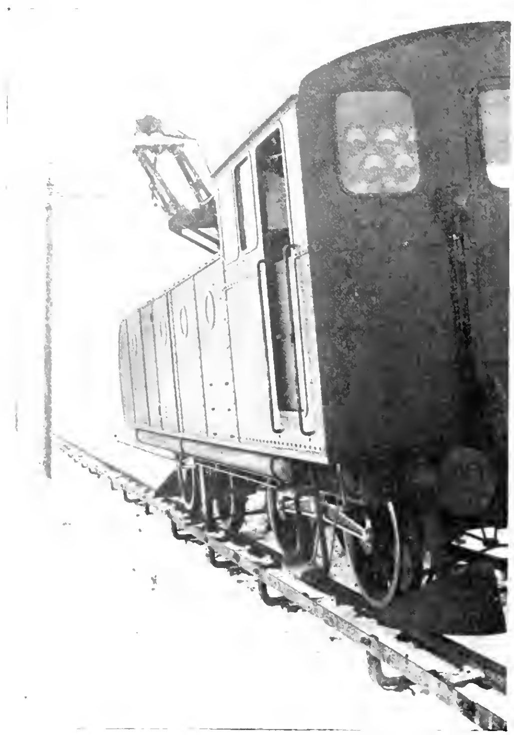

FIG. 3.—SIDE VIEW OF LOCOMOTIVE.

The Rivalry of Electricity and Steam.

The overlapping of the merits and claims of electric and steam traction have been noted for some time past, but they occupy more and more attention as the time goes by, and their struggles remind one of the early warfare waged on electric lighting by the advocates of gas. Within the past week the subject has been discussed by two leading organs of technical opinion, the *Railroad Gazette* and the *Street Railway Journal,* each authoritative in its own field. Both recognize the problems and difficulties of the situation, involved not only in a change of motive power, but in a necessary readjustment of conditions in many other respects. The *Street Railway Journal* regards the conditions as a deadlock, and says: "The flank movement executed by the railroads in securing important links in the electric railway network is a very adroit one, and will certainly block the union of interurban lines for through business in numerous instances. As a matter of public policy this attack must be in some way met, but it is rather difficult to settle on a course of action which will be both effective and unobjectionable. The general interests of the community are served by an increase in the facilities for transportation, and the fact that such an increase will injure somebody's previous monopoly of them is not a thing that should be considered any more than the introduction of improved machinery should be hindered, because it destroys the monopoly secured by an earlier patent. But whatever steps are taken to prevent the crippling of the development of interurban roads must be taken cautiously and without prejudice or malice." It also remarks: "We believe it is within bounds to say that upon the whole the electric roads operated by steam railroad companies are among the very best of the interurban class. Their managers bring to the work of construction and operation the best precedents of railroad practice, too often neglected by the independent roads, and the general results are worthy of high commendation. But for the full development of the usefulness of electric traction, so far as the public is concerned, and for the maintenance of earning capacity it is highly desirable that interurban lines, now generally run in a very heterogeneous fashion, should work in harmony and deal with through traffic of the less important kind at least. What is the use of having great electric railway networks, covering scores of hundreds of miles, if they cannot be fully utilized for want of proper management? The managers of interurban lines are rapidly finding out that through cars are a paying part of the equipment, and that it pays to use connections instead of disregarding them. Now, these connected systems, when properly operated, give to the public much better service than is generally given by the steam lines which cover more or less thoroughly the same territory, and are, therefore, competitors in the proper sense of the term. What shall be done about through connections in case the steam system acquires, by hook or by crook, one of the essential links in the electric interurban network?"

Turning to the *Railroad Gazette,* we find there a significant editorial discussion of the purchase of the trolley network at New Haven, Conn., by the New York, New Haven & Hartford Railroad Company, and, considering it under two aspects, physical and local, of President Mellen's policy in this move, it says: "He is prompted, no doubt, immediately by the threatened electric parallels of which two links are already built and two projected. There is nothing, it is true, to prevent absolutely such an extensive line from "looping" a city like New Haven in its advance toward New York City. But the physical obstacle is considerable, a cross-country line is bare of local business, and the tapping of important cities is vital to its success as both an immediate and remote competition. There are other questions which such a large purchase by a steam railroad corporation raises. For example, what is the policy of a steam company as the owner of both the steam and trolley competitors? Will the steam or the electric rivalry give way? The answer in terms of corporative common sense as well as of public interest is ready at hand. The electric traffic must be favored and the steam service reduced, the loss by the latter being of relatively small import so long as the receipts of both go to the same corporative pocket. To a second query the answer is more obscure. In the wholesale purchase of urban systems to block long-distance parallels, what will be the policy of legislatures toward long-distance lines with reference to the right of urban entry —either independently or over the purchased system under control of hostile interests? Hitherto, in general, the entrance of outside lines on unified urban street railway systems has had to be obtained by special contract and concessions, and even when there are general railroad statutes on the subject they are apt to be evaded in spirit and practice by the urban monopoly, whether steam or electric. Will such a policy give us a new and more drastic direction of law-making on interchanges of electric traffic? That it will at least promote some acute legislative controversy seems pretty certain.

"In more general phases still the New Haven precedent has large meanings. Experience has shown clearly at the west that direct interurban competition by the old steam companies with electric lines has been futile. But here is a new proposition: For competition by operation has been substituted the new method of competition by purchase, using the word "competition" here in its broadest sense to include prospective rivalry. The method, should it ever become generally accepted, introduces us to an entirely new set of theorems bearing on the relations of steam and trolley. Beyond lie even larger potentialities, such as bringing nearer the period when, with the great steam railroads operated with electric locomotives, and owning large urban street railway systems, the electric car, for purposes of local traffic, may duplicate service on the city street and the electrified steam line. It is not very remote, and the Fair Haven & Westville sale is one of the striking events that nods towards it."

One of the Groups in the Power Plant of the World's Fair.

BY THOMAS M. MOORE, CHIEF DEPT. MACHINERY.

The accompanying plan shows the arrangement of machinery in one of the sections of the Exhibitors' Power Plant of the St. Louis World's Fair. By reference to the installation plan for Machinery Hall, which accompanies this, and by reference to Block No. 36 thereon, it will be discovered what relation this particular block holds when compared with the total, for it must be borne in mind that the entire western half of Machinery Hall—that is, all the blocks from No. 36 to No. 53, inclusive—are devoted to prime-movers and accessories and the power plant of the Exposition.

The elements to be found in Block No. 36 are as follows: The principal unit, located in the center of the space, is a 5,000-hp Allis-Chalmers engine of the same type as the engines to be found in the Manhattan Elevated Railway power station in New York City. It is a compound condensing engine with a horizontal high-pressure cylinder (44 x 60-in.), and a vertical low-pressure cylinder (94 x 60-in.). Directly connected to it is a Bullock 3,500-kw, 6,600-volt, 25-cycle alternator. The normal revolutions are 75 per minute, and the current generated will be availed of for general lighting and power purposes.

The smaller engine is an A. L. Ide & Sons compound, with cylinders 13 and 26 in. in diameter x 18 in. stroke. Directly connected to this engine is a 200-kw, 250-volt, direct-current Bullock generator. About one-fourth of this energy is availed of for the excitation of the large Bullock alternator, and the remainder—about 150 kw—is passed through a balancer set and delivers multivoltage to motors driving machine tools exhibited in Machinery Hall, and operated by the Bullock multivoltage system.

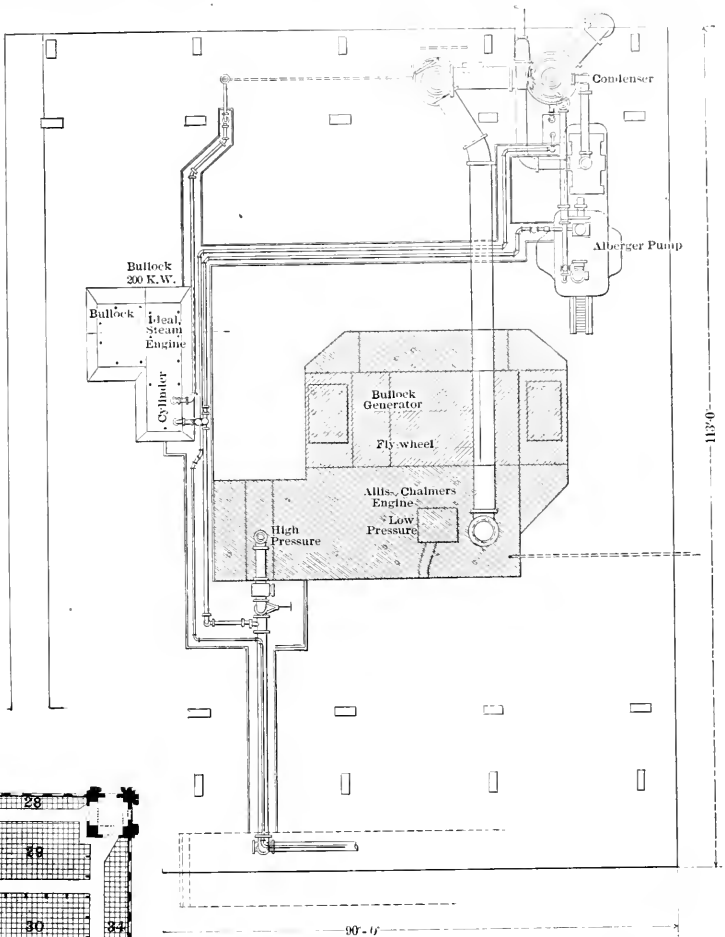

FIG. 2.—PLAN OF POWER EXHIBIT AT ST. LOUIS FAIR.

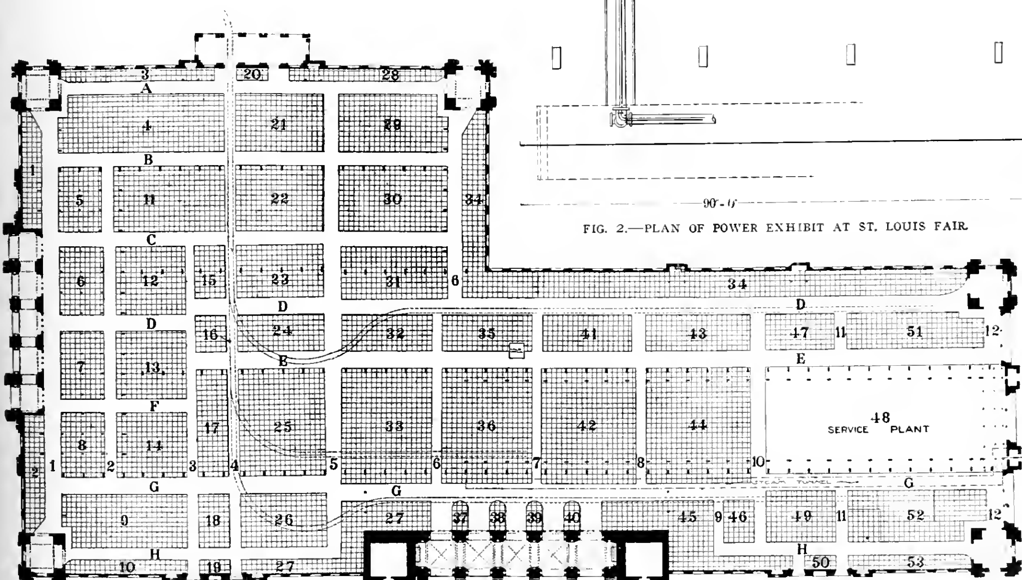

FIG. I.—INSTALLATION PLAN MACHINERY HALL, ST. LOUIS FAIR.

The steam for these engines is generated in the Steam, Gas and Fuels Building, located about 100 feet west of Machinery Hall, and the group of boilers furnishing this steam is approximately 750 feet distant from the engine installation. The steam is delivered at 150 pounds pressure at the throttles.

The condensation of the exhaust steam is taken care of by exhibits from the Alberger Condenser Company, of New York. The apparatus consists of a 36-in. barometric tube type condenser with air cooler and tail pipe complete and a combination vertical Corliss engine-driven vacuum-pump and a rotary circulating-pump. The condenser cone is elevated 55 feet above floor level. The steam traps, steam separators, oil separator and exhaust heads are exhibited by the Steam Appliance Company of Milwaukee, Wis. The pumps exhibited by the Morris Machine Works, of Baldwinsville, N. Y., and the Deming Company, of Salem, O., take care of, respectively, the return water and the freeing of the oil separator.

The total installation is rapidly approaching completion, and if nothing now unforeseen prevents the plant will be ready for operation by or about the first of April. The erection of the machinery has been effected by the 60-ton traveling crane, with a 5-ton auxiliary, built and exhibited by the Shaw Electric Crane Company, of Muskegon, Mich. The heaviest piece in this installation weighs 83 tons and this was handled with the utmost ease by the Shaw crane.

New Telephone Patents.

THE REPEATER AGAIN.

Still another repeater has come to light, this time described in a patent issued to S. P. Levenberg, of New York City. This is shown in section in Fig. 1. It will be noted that the microphone part is not in the usual position with reference to the diaphragm of the receiving part, but is located with its electrodes in a plane perpendicular to that of the diaphragm. The diaphragm is not rigidly secured, but lies upon the top of a hard rubber annulus. Projecting from this annulus in a downward direction, at opposite extremities of a diameter, are two lugs of sheet metal. The left-hand one, as shown in the cut, is secured to the frame of the instrument by screws passing through its lower end, while the right-hand one is secured directly to the movable electrode of the transmitting button. The diaphragm is, of course, capable of taking two sorts of motion—a vibration confined to itself and a swinging motion about the hinging lug.

It is the idea of the inventor that this latter motion will produce an effect upon the transmitter far in excess of anything which could be produced by direct action of the diaphragm. However, the bulk

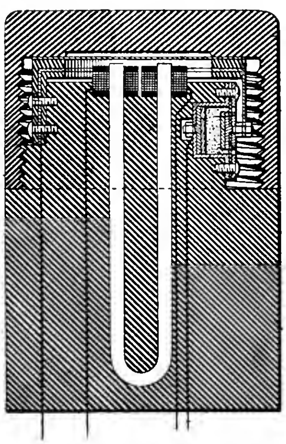

FIG. 1.—LEVENBERG TELEPHONE REPEATER.

of the moving parts will surely introduce a sluggishness of action quite fatal to the quality of the repeated tone.

NEW RELAYS.

Mr. H. P. Claussen, of Chicago, has produced a new relay for telephone signal work which embodies most novel means for preventing sticking of the armature due to incipient welding of the contact to its anvil. Considerable trouble is at times experienced from this cause, especially where a condenser of a high capacity line or apparatus is in the controlled circuit. The new relay in question is of the double-bobbin type, much in appearance like an ordinary telegraph relay of which the plane of the coils has been turned parallel to that of the direction of armature swing. The usual adjustable screw stop and adjustable contact screw of this telegraph relay are provided, supported from a frame to which the bobbins are secured. Upon the rear of the armature is secured a slip spring riveted near the middle of the armature. One end of this is engaged by an adjustable screw and secondly the metal crown would apparently be almost as good spring carries the contact anvil, which is placed on the side of the spring nearest the armature and opposite an aperture in this latter. Thus, when the armature comes up for contact, the contact screw passes clear through it without resistance, and, striking the contact anvil, forces the spring away from the armature. When the current ceases the armature begins its backward travel and strikes a hammer blow upon the contact spring sufficient to break any weld which may have occurred.

Another new relay is one patented by M. C. Rorty, of Boston. This is a single-core relay with a return pole piece lying above the coil and serving as a hinge and support for an angular armature, after a well-known design. A novel feature is, however, the polarization of the relay by the mounting of a permanent magnet of U form with one pole clamped to the yoke end of the core of the bobbin, while the other pole confronts its free end. The design is such that a dust-proof cap of standard construction may be readily used, as may be seen from a glance at Fig. 2, which shows side views of both Mr. Claussen's and Mr. Rorty's relays. Of the two patents, that of the first-mentioned of these gentlemen has been assigned to the American

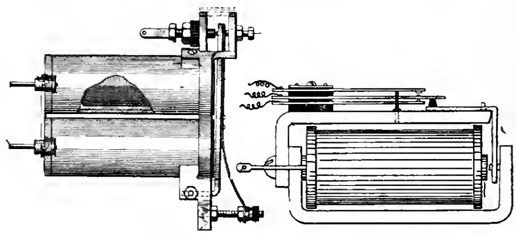

FIG. 2.—CLAUSSEN AND RORTY RELAYS.

Electric Telephone Company, while that of the latter is assigned to the American Telephone & Telegraph Company.

SOME NEW CIRCUIT ARRANGEMENTS.

Two patents for new circuit arrangements have been issued, the one to F. R. McBerty, of Evanston, Ill., relating to message-counting devices, and the second to E. H. Smythe, of Freeport, Ill., covering new connecting cord and trunk circuits. Both patents are assigned to the Western Electric Company.

It is Mr. McBerty's idea to so control the push-button type of message counter that it will be impossible for an operator to register a message before the called party has answered. It will be recalled that the type of counter in question is usually wired in parallel with the subscriber's cut-off relay, but is insensitive to the currents received in normal connection. To operate it a high current from an excessive source of potential must be thrown upon it by a push key under control of the operator. In the present case an electrically-controlled latch restrains this key until the controlling magnet is energized by the response of the called subscriber as indicated by his removing his receiver from the hook. From this time on a call may be registered, the latch being held from the key during the remainder of the connection.

Mr. Smythe's circuit includes extra switching devices in both trunk and connecting cord circuits, arranged to remove all grounds from the trunk line or along side of a through connection, and thus avoid the disturbing effects of two widely separated grounds. The control of the new switching devices is, in the case of the trunk, associated with the hook switch of the called subscriber through the agency of his supervisory relay, while in the case of connecting cords differentiation between subscribers' and trunk lines is made by the removal of the ground connection from the jack sleeves of the latter class of line.

PARTY LINE SWITCHING APPARATUS.

Two switching devices for party lines are the respective subjects of patents, one of these latter being issued to C. H. Prött, of Germany, and the other to Messrs. T. W. Gleason and R. Hamilton, of Boston, Mass.

The system of the former gives the primary control of the line to a main station, which is to receive the central office signals and transmit them to the desired station through a manual switching commutator. As soon as a connection is completed, an electromagnetic lock at each station prevents interference from those stations not involved in it. Each sub-station has a manually-operated commutator for calling the central office or selecting any of the other line stations, the same lock-out conditions existing as for an incoming call.

The second system employs electrically-operated automatic switches working on the step-by-step principle. These are controlled for all stations from any one, by circuit-making and breaking devices, which, through resulting current impulses on the line, rotate selective commutators at each station. Complete lock-out and automatic return of the selective commutators is provided, all the functions being carried out over two line wires, which also serve as the talking circuit.

Recent Electrochemical Developments.

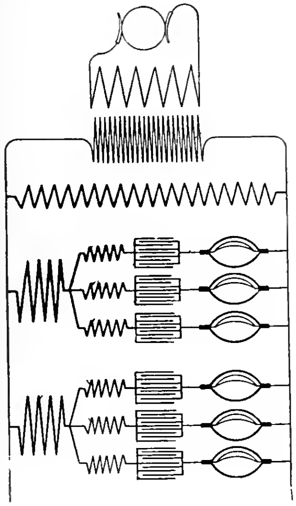
ELECTRIC MANUFACTURE OF IRON ALLOYS.

For the electric furnace production of iron alloys, such as ferro-silicon or ferro-manganese, with the simultaneous production of alkaline oxides or alkaline earths, a patent was granted on March 8 to G. Gin, of Paris, France, who has in recent years been an active worker in the application of electrical methods to the metallurgy of iron and steel. His new process may be best explained by its application to the production of ferro-silicon and baryta.

The process consists of two steps. In the first step, which does not necessarily require an electric furnace, since a high temperature is not required, he subjects a mixture of broken quartz or non-clayey sand, barium sulphate and charcoal to a heating action to produce barium silicate. The barium silicate is then mixed with an oxide of iron or metallic iron and carbon and treated in a second operation in an electric furnace to produce ferro-silicon and barium oxide. The latter is collected in the form of a sublimate.

FIXATION OF NITROGEN FROM THE AIR.

In view of the enormous commercial consequences which a successful economical solution of the problem of the fixation of nitrogen from air would have especially in agricultural chemistry, the work undertaken by Bradley and Lovejoy at Niagara Falls has aroused great interest all over the world. Naturally other workers have entered the field. A patent granted to J. von Kowalski and I. Moscicki, of Freiburg, Switzerland, relates to the same problem. Their apparatus is shown in Fig. 1. The secondary of a transformer supplies



KOWALSKI AND MOSCICKI METHOD OF PRODUCING NITROGEN, ETC.

alternating current to mains across which are connected in parallel a main induction coil and a number of groups of induction coils, condensers and air-gaps, in a manner clearly seen from the illustration. Across the air-gap a series of sparks in the nature of an arc is produced, and the desired nitrogen compounds are obtained from the air.

The inventors give the following data taken from a plant for the production of nitric acid: The secondary circuit had an e.m.f. of 50,000 volts, producing spark arcs of about 24 cm. length in each gap. In each consumption branch the current was 0.05 amp. and the frequency about 6,000 cycles per second, while the frequency of the alternating current in the secondary circuit outside the consumption branches was 50 cycles per second. The apparatus required 33 hp, and with these were obtained 1,155 grams of nitric acid per hour from atmospheric air; that is, 35 grams of nitric acid per hp-hour. It was found that the frequency of the current in the consumption branch should have a minimum of 6,000 cycles per second and a maximum of 10,000 cycles per second.

To produce a frequency between these limits the induction coils and condensers shown in the illustration must be properly proportioned. By applying several condensers in parallel the inventors intend to get a sufficiently high frequency, while the inductance coil in series with each condenser prevents the frequency from overstepping the maximum limit. The inductance coil in series with each group of inductance coils and condensers is intended to maintain the original frequency of the alternating current in all parts of the secondary circuit outside the consumption branches, by preventing the propagation of the oscillatory currents by the condenser beyond its respective consumption branch. The main induction coil which is connected across the mains and which is in parallel with all the different groups of consumption branches is intended to eliminate the production of a wattless component in the secondary circuit in order to maintain a high efficiency.

The predetermination of the different inductance coils and condensers suggests the solution of a problem which is not electrochemical, but distinctly in the realm of alternating-current engineering. The ordinary methods of treating alternating-current phenomena, like Steinmetz's symbolic method, are, of course, not applicable to this case, because the fundamental supposition of their application is that there is a constant frequency all over the circuit. What the inventors disclose in their patent is a method of producing and maintaining a frequency between certain limits. There are, of course, analytical methods by which this problem can be treated with the aid of calculus, but a method of the same simplicity and beauty as Steinmetz's method for dealing with the phenomena in a circuit of constant frequency, has not yet been devised for describing the transformation of frequencies.

MISCELLANEOUS.

The porosity of carbon electrodes is one of the reasons which cause their quick disintegration. There is also experienced a creeping of the solution upwards with a resulting corrosion of the metallic connections. The latter disadvantage has even been experienced with artificial graphite electrodes which are otherwise much superior to, and much more porous than, ordinary carbon, and to overcome this disadvantage, the electrodes have often been impregnated with paraffin with good success. A patent granted to G. J. Atkins, of Tottenham, England, refers to a similar method, the special feature of which seems to be the use of an oxidisable oil, such as linseed oil or cottonseed oil. The disadvantages claimed are that the oil is gradually oxidized and forms an insoluble material which is not attacked by the electrolyte and does not melt when the electrode becomes warm.

The production of ozone from air—for the purpose of using the ozone afterwards for the sterilization of water—depends upon the production of silent discharges and the prevention of arcs. For this purpose solid dielectrics like glass are often resorted to, as for instance in the ozonizer of Siemens & Halske. The objectionable feature of this is that the glass may break, so that no ozone is formed and the water is not sterilized. In order to get along without solid dielectrics A. Vosmaer and A. Lebret, of Amsterdam, Holland, have studied the conditions under which silent discharges without arcs are produced in an air-gap. From a paper of van't Hoff of last year it appears that their system has been in successful use for some time in Holland. In a patent granted to them on March 8, they state that silent discharges depend upon a high voltage and a low current, and are best produced by connecting the air-gap in shunt with a condenser to the terminals of the secondary of a transformer, an induction coil being inserted between the secondary of the transformers and the condenser.

A patent granted to A. Müller, of New York City, refers to mechanical details of a battery stopper, for preventing the spilling of the battery liquid.

Fessenden Wireless Telegraph Patents.

Three new patents were issued March 8 to Prof. R. A. Fessenden. Of these one[1] is a subdivision of No. 753,863 and relates to wireless signalling as described in a previous article. The second patent[2] embodies specifically a radiator or resonator system as shown in Fig. 1, made in the form of a cone and having a large capacity. The cone may be made of sheet metal or formed of a network of wires. This horizontal metal cone serves to deflect the radiated waves and direct them along the surface of the earth. A horizontal conductor, the length of which is equal to the base of the cone, extends in the direction the waves are to be propagated and may include an inductance, as shown.

The third patent[3] relates to a method of transforming alternating currents into high-frequency oscillations by operating a generator with a steam turbine. The inventor points out in this particular specification that where a reciprocating steam engine is used to

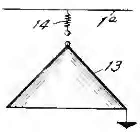


FIG. 1.—RADIATOR.

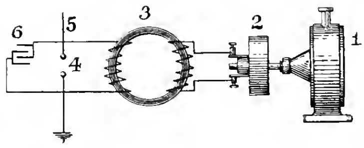

FIG. 2.—ALTERNATING-CURRENT GENERATOR CONNECTED TO STEAM TURBINE.

actuate a generator it is not possible to obtain a high peripheral speed of the moving coils of wire; that is to say, 3,000 or 4,000 r.p.m. are not nearly great enough and to obtain speeds of 25,000 or 30,000 r.p.m. a steam turbine must be employed.

By referring to Fig. 2 the steam turbine is represented connected to a revolving-pole alternating generator operating a transformer. The increased potential from the secondary charges the condensers, which finally disrupt an air-gap and so sets up oscillations in the radiator system, 5; thus a high peripheral velocity with small circumference of moving parts may be obtained.

The advantages of this improvement are illustrated by numerical statements. It is claimed that a fundamental and radically new effect is obtained by employing a prime-mover having a constant torque to operate a generator armature of small diameter, as for example, two feet—and a high peripheral speed—as for example, ten miles per minute. If the pole pieces have a width of one-twentieth of an inch a periodicity of 100,000 per second may be obtained. With a reciprocating engine giving 600,000 r.p.m. the diameter of the armature would have to be 260 ft. to give the same number of periods per second with the same width of pole pieces.

Many advantages of this new combination are pointed out by its designer, among the more important being that the torque is exceedingly uniform; a high peripheral velocity reduces the number of poles and hence eliminates largely disturbance from resonance; there will be a smaller change in periodicity when signals are sent and the generator will not be thrown out of resonance; a light and portable wireless telegraph set may be constructed and such a set will not give rise to vibrations to disturb the operation of the station.

Meeting of the Iowa Telephone Association.

The eighth annual meeting of the Iowa Telephone Association was called to order Tuesday afternoon, March 8, at Des Moines, by the vice-president, Mr. J. C. Sullivan. The meeting was adjourned until Tuesday evening. After the appointment of the committee on credentials at that session, the annual address of the president was given, his topic being "Combinations and their Necessity in the Telephone Business in Iowa." The subject of "Long-Distance Lines" was handled by P. C. Holdeogel, of Rockwell City.

At the session Wednesday morning "Farm Lines" were discussed in many details and phases. The subject seemed to be an interesting one to most of those present, as it evoked a great deal of discussion. Papers presented at this session were: "Jealousy Among Independent Telephone Men," by H. E. Ralston, of Maitland, Mo.; "Operating a Telephone Plant as a Side Line," J. C. Thorne; "Our Business Relations," Paul H. Patton, of Waterloo, and "Our Loyalty to the Principles of the Association," by H. A. Kinney, of Woodbine.

A special session was called for Wednesday afternoon to discuss the papers of D. M. Griswold, of Des Moines, on "Necessity of Uniformity in Toll Line Service and Rates," and by J. M. Plaister, of Ft. Dodge, "Shall We Establish a Clearing House?" The discussion brought out the fact long realized by many that there is urgent need for a clearing house or similar office, but the meeting was somewhat divided as to the scope of a plan and the details to be arranged.

On Wednesday evening about 200 of the members of the Association and their friends sat down to a dinner served at Our Circle Hall. Following the banquet, Mr. U. S. Alderman, acting as toastmaster, called on Governor A. B. Cummins for an address which was largely in the nature of a welcome. The Hon. Lafayette Young spoke on the subject, "A Long-Distance Hot Wire." Mr. Young was in a very happy vein, and thoroughly entertained his hearers. Mr. A. L. Urick, of the State Federation of Labor, spoke on the "Relation of Employer and Employee," and was listened to with great interest. Judge Nichols responded to the toast, "Service," with a very fine address.

At the last session which was held Thursday morning, E. H. Martin, of Webster City, had for his topic, "How Can We Promote Better Feeling Among Toll Operators, Inducing Harmony, Improving Our Service, and thus Reducing the Lost Call Record?" The following were elected officers for the ensuing year: J. C. Sullivan, of Creston, president; S. S. Lichty, of Vinton, vice-president; Charles C. Deering, of Des Moines, secretary and treasurer. Executive Committee—J. S. Bellamy, of Knoxville; J. C. Thorne, of Fairfield; P. C. Holdeogel, of Rockwell City, and W. S. Alderman, of Nevada.

Among those present, on behalf of supply concerns, and representing local telephone companies were: H. McCartney, J. C. Sullivan, Geo. E. Atkinson, Charles C. Deering, George N. Bandy, J. S. Bellamy, R. S. Redman, S. S. Lichty, J. C. Thorne, Paul H. Patton, J. M. Plaister, G. F. Bygel, M. I. Berger, G. O. Lundgren, S. A. Dinsmore, F. L. McGillen, W. B. Swaney, E. H. Martin, W. E. Doolittle, J. E. Keelyn, E. B. Overshiner, F. C. Musson, W. R. Hind, W. H. Trimm, A. J. Carter, Wm. Bowen, Fred Walthauer, H. A. Jones, W. S. Arnold, F. M. Boardman, N. G. Harvey, M. McNeill, P. J. Eubanks, H. P. Blackledge, W. R. Hauptman, W. O. Bryan, H. S. Durant, E. J. Pietzcher, W. J. Crawford, B. J. Carney, A. L. Plummer, C. C. Keister, A. T. Whittle, P. C. Holdoegel, J. H. Bradt, Claus Anderson, Francis Anderson, O. C. Cochran, O. A. Repass, H. A. Kinney, H. L. Bell, H. E. Ralston, F. H. Jones, J. W. Brown, H. U. Anderson, L. L. Bowlin, Senator Brooks, G. W. Greaves, J. A. Brown, Charles R. Kirk, Mr. Shipley, Mr. Brooksmith, H. H. Herr, F. E. Dupee, W. O. Wells, F. W. Lindquist, S. E. Weitzel, W. D. Dunsmore.

Telegraphy and Telephony in Germany.

According to the statistics of the German Federal Post Office and Telegraph Department for 1902 all branches show an increase, though the number of telegrams is somewhat reduced, the result of the extension of the telephone system. The number of federal telegraph offices was 22,292, against 21,150 in 1901; that of telephone offices, 16,292, against 15,200.

The total personnel of the federal post-office and telegraph service at the end of 1902 was 209,906 persons, being an increase of 7,319 persons, or 3.6 per cent. over 1901. Among this number were 85,267 full officials (82,861 in 1901), inclusive of 9,562 (8,963 in 1901) females. The number of post and telegraph offices owned by the Federal Government increased from 476 in 1901 to 490 in 1902. The number of telegrams was 41,118,729, against 41,125,033 in 1901, being a decrease of 6,304.

The telephone conversations, however, increased from 692,687,730 in 1901 to 757,648,580 in 1902, an increase of 75,000,000 per year, or over 200,000 per day.

Single Phase Traction Meeting in Chicago.

The Chicago branch meetings of the A. I. E. E. of this year, in every case, have exceeded the seating capacity of the Western Society of Engineers' meeting room, which seats about 100. The meeting for the discussion of single-phase traction systems was, everything considered, the most successful meeting of the Institute ever held in Chicago, quantity and quality of attendance both being considered.

President Arnold presided at the meeting, and in response to a number of references by various speakers to the part he had taken in the pioneer work of bringing about a realization of the necessity for some single-phase alternating-current traction system, expressed his appreciation, and said that it was always a pleasure to see one's prophecies come true.

The discussion of the subject was opened by Mr. Clarence Renshaw, who took up the theory of both the single-phase series motor and the repulsion motor. In analyzing this question he said that the single-phase repulsion motor, while it did away with the necessity for a step-down transformer on the car (since the fields of the motor could be operated at a high voltage) the increased weight of the repulsion motor, with its high-voltage field windings, was enough more on a four-repulsion motor equipment than on a four-motor equipment of series single-phase motors to counteract any saving in weight due to the absence of a transformer on the car equipped with the repulsion motor.

The operation of a series single-phase motor on direct-current trolley lines, while quite possible, was not recommended by him as good engineering except where it was absolutely necessary. In most cases where an interurban car comes over city lines, he thought that the running of a second trolley wire was advisable, so that the interurban cars could operate with alternating current. If the series single-phase motor car was to be run from direct current it must be equipped with rheostatic control, and this wiped out all of the economies possible by the use of induction control for accelerating and slow-speed running.

Mr. W. A. Blanck presented a paper giving the comparative cost of a sixty-mile interurban railway electrical equipment with direct current supplied from sub-stations and with single-phase alternating current. Mr. Blanck's figures showed a difference of about $2,000 a mile in favor of the single-phase alternating-current system.

CURRENT NEWS AND NOTES.

CONTRABAND.—The Russian war regulations declares telegraph and telephone material as being on the contraband list.

THE METRIC SYSTEM IN GREAT BRITAIN.—The House of Lords has unanimously passed a bill making compulsory the metric system in Great Britain on April 5, 1906, or at such later date as may be directed by an Order in Council.

MONORAIL IN ENGLAND.—During the past week a model of the Behr monorail system, proposed for installation between Liverpool and Manchester, has been shown in London. It seems high time something was done to build that line, of which we have now heard so much.

WRECK OF CABLE STEAMER SCOTIA.—The good old *Scotia*, a cable steamer known to a great many of our readers, is, it is feared, a total wreck in the Pacific. A special dispatch from Washington, D. C., of March 12 says: "Wrecked within a short distance of a safe harbor, the crew of the cable ship *Scotia* was rescued by the naval garrison at Guam. The supplies carried by the ship, which were intended for the Commercial Pacific cable station at Guam, have been partly saved, but the ship is apparently a total loss. Lieutenant Raymond Stone, Acting Governor of Guam, sent a cablegram, dated yesterday, to the Navy Department, in which he said: 'Cable ship *Scotia* has been wrecked on Callahan Bank, coming in, March 11, northeast and north Spanish rock five hundred feet approximately. Leading marks intact; entrance buoy is partly sunk. Vessel is lying in dangerous position, but cargo can be recovered if wrecking vessels arrive while weather continues favorable. I am rendering assistance with all resources available. I am feeding and sheltering part of the crew on shore. *Scotia* suffered from want of provisions. Ship probably totally ruined. No wrecked people lost.'"

INSTITUTE NEW YORK MEETING.—The 185th meeting of the American Institute of Electrical Engineers will be held at the Chemists' Club, 108 West Fifty-fifth Street, New York, Friday, March 25, at 8.15 P.M. The following papers will be presented for discussion: 1. "The Relative Fire Risk of Oil and Air-Blast Transformers," by E. W. Rice, Jr., technical director of the General Electric Company, Schenectady, N. Y. 2. "Use of Group Switches in Large Power Plants," by L. B. Stillwell, electrical director of the Interborough Rapid Transit Railway Company. 3. "Oil Switches for High Pressures," by E. M. Hewlett, engineer of the General Electric Company, Schenectady, N. Y. 4. "Terminals and Bushings for High-Pressure Transformers," by Walter S. Moody, electrical engineer with General Electric Company, Schenectady, N. Y.

NATIONAL ELECTRIC LIGHT ASSOCIATION.—Mr. Charles L. Edgar, president of the National Electric Light Association, was in New York several days this week looking after Association affairs. President Edgar was accompanied by Past-President James I. Ayer, whom he has been fortunate enough to induce to act as chairman of the entertainment committee of the twenty-seventh convention, to be held in Boston May 24-27. The entertainment committee, among its other duties, will have charge of assigning rooms at the Vendome, which is to be the headquarters of the Association, and particulars regarding rates, etc., will be issued very soon. As delegates sometimes prefer to stop at a smaller or quieter hotel than that selected for convention headquarters, arrangements will be made by which they also can secure through the committee such accommodations as they prefer. In fact, hotel arrangements promise to be more systematic and satisfactory than on previous occasions.

RAYING OUT WAR SCARS.—A special dispatch from London says: "London has a new scientific surgical sensation in the application of the Finsen rays—which are apparently allied to the Röntgen—for the removal of scars following wounds, whether inflicted in war or by the surgeon's knife. Lately quite a number of British subalterns have sought out the "light-curer" for the removal of face wounds received in South Africa. The custom is rapidly growing of surgeons sending their patients to have the scars left by operations removed. A "light-curer" gives the following description of the process: "Repeated applications of the Finsen light in a powerful form are given until the blood corpuscles are stimulated to such an extent that, by distension of the cells and other resultant processes, new tissue is formed and scars disappear."

STAFF FOR SIGNAL SERVICE.—The United States Civil Service Commission announces an examination April 6-7, 1904, to secure eligibles from which to make certification to fill vacancies in the position of assistant electrical engineer in the Signal Service at Large, Washington, D. C., at $1,400 per annum, and other similar vacancies as they may occur. The examination will consist of the subjects mentioned below, which will be weighted as follows: 1. Theoretical and practical questions in electrical engineering, 75. 2. Technical training and experience (rated on application), 25; total, 100. Two days will be required for this examination. Age limit, 20 years or over. Applicants for this position should have a good general knowledge of electrical science, and should be thoroughly familiar with telephone, telegraph and cable engineering. This examination is open to all citizens of the United States who comply with the requirements. Competitors will be rated without regard to any consideration other than the qualifications shown in their examination papers, and eligibles will be certified strictly in accordance with the civil service law and rules. Persons who desire to compete should at once apply either to the United States Civil Service Commission, Washington, D. C., for application Form 1312, which should be properly executed and filed with the Commission at Washington. Persons who are unable to file their formal applications and who notify the Commission of this fact, either by letter or telegram, with the request that they be permitted to take the examination, will be examined, subject to the subsequent filing of their applications, provided their requests are received at the Commission in sufficient time to ship examination papers.

Letters to the Editors.

The Theory of Wireless Telegraphy.

To the Editors of Electrical World and Engineer:

Sirs:—I beg to thank you for having given space to my communication of January 2 and for the favorable comment in your editorial of January 16. I am entirely in accord with the views which you express in this editorial and I find of much interest the hypothesis in which you complete my modest contribution—necessarily very incomplete—by the consideration of a conducting atmospheric stratum forming a second and parallel surface at a height of about 50 miles. One may have doubts, it is true, on the manner in which such a stratum conducts, since it would probably follow laws of conduction different from those applying to metals; but the hypothesis is none the less interesting and it could be verified up to a certain point by a study of the law of distances. Properly speaking, the theory which I have sought to develop applies for distances much smaller than those at which the upper stratum intervenes, and it may be in error for greater distances. The quantity of energy received by an antenna would then first decrease according to the law of inverse squares of the distance, and next simply inversely with the distance. It is to be understood that I entirely agree with you on the subject of superficial currents, of which the earth is the seat and which establish the electrical junction between the lines of force ending normally at the earth, for each half wave. If we imagine a symmetrical antenna beneath the surface, supposed to be equivalent to a thin layer, superficial currents equal and of opposite signs would be produced in this layer and annul the preceding ones. This justifies us in saying that a system of an antenna and earth is equivalent, from the standpoint of action at a distance, to a system of the antenna and its image.

I have also read with much interest the letters which my communication has brought forth from Prof. Fessenden and Mr. Taylor. It is somewhat amusing to find that they are in complete contradiction with each other, which, however, was easy to predict. My position with respect to them is rendered more simple for the reason that I do not pretend to have made a great invention, but merely to have understood rationally, by the exercise of simple common sense, existing theories; and I do not think there is any need of inventing half waves as Prof. Fessenden has done, nor sliding waves as Mr. Taylor has done, for the simple reason that these waves have long been known from the work of Hertz.

As to the other remarks of Prof. Fessenden, I am entirely disposed to be in complete agreement with him when experiment has enabled me to appreciate the practical value of his new bolometric detector, which, up to the present, I have not had an opportunity to examine closely. In principle the employment of the bolometer would appear to offer an excellent solution to the problem of syntonic reception. I am not sure, however, that the gold coherers tested by Prof. Fessenden were of the same type as my own. I am happy to note that the theoretical ideas of Prof. Fessenden have many points of contact with my own.

With respect to the remarks of Mr. Taylor, I note with pleasure his emphatic affirmation that his theory is different from mine; and since he desires it I am entirely ready to give in detail my objection to the "erroneous ideas" which he reproaches me with having criticised without proper examination.

1. The form of the waves indicated by Mr. Taylor is incompatible with a propagation with the velocity of light, for the crest of the waves of Mr. Taylor are displaced tangentially to the lines of electric force, which is contrary to the principles of the propagation of electromagnetic waves, which are always propagated transversely. At all points of electromagnetic waves, according to the theorem of Poynting, the propagation of energy is directed according to a vector perpendicular at the same time to the lines of electric force and to the lines of magnetic force; whereas Mr. Taylor would have an energy vector tangential to the lines of electric force at the crest of the loops of the waves.

2. The distinction which Mr. Taylor makes between waves propagated in free ether and along a wire does not conform to established principles, and the citation which he makes from the work of Hertz cannot justify it. Hertz has, indeed, indicated a form of wave along wires analogous to that which Mr. Taylor cites (work of Hertz, German edition, Vol. II, page 167, Fig. 32B); but he was careful to point out that this form applies only to waves having a velocity less than that of light, and should be replaced by the form *C*, corresponding to a transmission purely transversal if the propagation of waves takes place with the velocity of light. Hertz was very much astonished that his experiment on propagation along conductors had given him only results contrary to the theory of Maxwell, and expressed the greatest doubt on the subject of the correctness of the form 32B. Since that epoch, however, numerous experimenters, notably M. Blondlot, in 1891, have shown that the experiments of Hertz were inexact on this point, and that the propagation along wires takes place with the velocity of light, thus contradicting the result found by Hertz. If, then, Mr. Taylor wishes to apply the theory of Hertz, it is necessary to adopt the form 32C and not the inexact 32C which he has chosen.

3. There is no identity between the case of propagation along a wire and the case of propagation along a plane surface. A wire necessarily produces a *concentration*, for it is surrounded with lines of electric force perpendicular to its surface and radiating all around it; and nothing similar is produced in the case of a plane surface. Besides, all the experiments with propagation along wires are made in reality with two conductors; or rather, two parallel wires are employed between which the field is concentrated, or a wire is stretched horizontally above the earth, in which case the earth itself serves as a second conductor, and the field is concentrated between the wire and the earth. Nothing resembling this occurs in the case of a vertical wire. One can easily conceive that in the case of two parallel conductors the energy remains concentrated between them and there is no loss from radiation since there passes simultaneously through the two wires current of opposite sign. On the contrary, in the case of a plane surface, there is nothing to prevent natural propagation and radiation. If the antenna produces effects at great distances it is precisely because it is alone and no parallel conductor intervenes to reduce its radiation. If one used two vertical antennæ, one alongside of and parallel to the other, and connected with opposite electrodes, according to the arrangement ordinarily employed in the study of propagation along wires (methods of Lecher, Blondlot, etc.), no effect occurs at a distance.

4. My theory does not prevent in any manner the admission that waves are guided by conductors, since on the contrary we know that they are guided at their lower portion by the ground. It may be that the curve of distribution to which calculation leads does not correspond exactly with reality, and that the energy remains more concentrated at the surface of the soil; experiments alone can establish this, but even if it is shown, this will not contradict the fact that the propagation is transversal by polarized hemispherical waves, as I have pointed out. It would simply prove that the distribution of the energy in these waves differs somewhat from that which the elementary theory developed indicates; or rather, that the energy is absorbed more quickly by the gaseous medii of the atmosphere, than in the immediate neighborhood of the soil. Moreover, there is no incompatibility between this general propagation by hemispherical waves and local deformation of waves produced by irregularities of the ground. The phenomena of diffraction are in no respect denied by the general conception of spherical waves.

5. As to the form of the lines of force, which seems so extraordinary to Mr. Taylor, it is much less so to my mind than that of lines of force studied by Hertz. (*Loco citato,* pages 156-157). If Mr. Taylor will read the explanations of Hertz, he will see how much more complicated in reality is the movement of these waves than I have assumed; he will also see that the waves of Hertz attain the same final form as that which I have indicated.

6. As concerns the velocity of propagation of waves, Mr. Taylor reproaches me with supposing that the velocity of light is only attained after a certain number of wave lengths from the source, which he says is in conflict with known laws, provided *disturbing factors in the way of reflections, interferences,* etc., are absent. To this my reply is that there *is* a phenomenon of wave reflection at the summit of the antenna, and that I have specified nothing concerning the number of wave lengths after which the velocity of propagation becomes equal to that of light. Moreover, this distance matters little so far as concerns the results; that is to say, as to the final hemispherical form taken by the waves and the general manner in which they become deformed after leaving the origin. I shall

be happy if these explanations serve to convince Mr. Taylor, or if they should be found of interest by your readers.

PARIS, FRANCE. A. BLONDEL.

Sale of Power by Municipal Plants.

To the Editors of Electrical World and Engineer

SIRS:—An article in the ELECTRICAL WORLD AND ENGINEER of February 20 on the new installation at the City of South Norwalk Electric Works, by A. E. Winchester, came to my notice recently and I wish to call attention to an erroneous statement with reference to rates. He says: "For a continuous consumption of say 50 hp, measured by the customers' meters, the rate would be 1.9 cent per horse-power-hour, corresponding to $4.95 per month of 26 10-hour days. There is no place known where power can be obtained so cheaply."

I take exception to the assertion that "there is no place where power can be obtained so cheaply," and think before the municipal central station superintendent makes an erroneous statement and attempts to mislead others by presuming that a municipal plant is the only one from which cheap power can be obtained, that he should make some effort to inform himself of rates in vogue in other cities and towns. The assertion may sound well in his own city, but to those of us who know better it is absurd. However, it is in the same strain of the rest of the misleading statements that emanate from the mouths of the municipal central station promotors or advocates.

The writer knows of cities and towns in his own neighborhood that sell current for less than 1.9 cents per horse-power-hour, and give 24 hours' service and furnish free lamp renewals. As one who is opposed to the confiscation of property, I believe with you that every misleading statement emanating from the agitators of municipal ownership, should be called to account.

ONEIDA, N. Y. C. W. KOINER.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

DYNAMOS, MOTORS AND TRANSFORMERS.

Progress in Dynamo Design.—LOEWY.—The first part of an illustrated summary of the progress made in dynamo design in the year 1903. The author first discusses new designs of direct-current machines. Generators with compensated armature field and with devices for preventing sparking are of special interest. He describes at some length the compensated machine of Ziehl. The field magnet is designed and wound like the stator of a three-phase machine. The winding of phase *I* in Fig. 1 is in shunt to the armature when the machine is a dynamo, and across the supply mains when the machine runs as motor. It serves for generating the exciting field, *Me*. The other two phases of which one, for instance, *II*, is wound in a direction directly opposite to that ordinarily used in three-phase machines, are supplied with the armature current and serve for producing the field, *Mg*, which is of the same size, but of opposite direction, as the armature field, *Ma*, so that the latter is compensated. In Fig. 2 the drawing at the top shows the three windings, the next one gives in dark lines the field, *Mg*, which results from composition of the fields *II* and *III*. The drawing at the bottom shows the field, *Mg*, as it really is in practice, as well as the exciting field, *Me*, and the armature field, *Ma*, which is completely compensated for by the field, *Mg*. In using this method for the connections between an alternator and its exciter, the armature reaction is annihilated and the generator gives the same voltage at any load. Instead of giving the same ampere winding to *II* and *III*, it is possible to increase the ampere winding of one and diminish those of the other by the same amount, which may be accomplished by means of a regulating resistance connected in parallel to one phase. If the ampere windings of *III* are increased, the exciting field, *Me*, is strengthened, while by increasing the ampere windings of *II*, the exciting field, *Me*, is weakened. It is thus possible without regulating the current in winding *I*, which produces the exciting field, *Me*, to change the value of this field and thus to change the voltage of direct or alternating current or polyphase machines when loaded or to change the number of revolutions of direct-current motors and to change the phase difference of synchronous motors or three-phase to direct-current converters. In order to use more stator windings for the generation of the exciting field, it is possible to make use of two of the three windings for this purpose and to generate the opposing field with the third one only.—*Zeit. f. Elek.*, February 21.

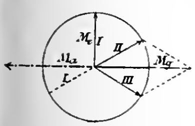

FIG. I.—PHASE DIAGRAM.

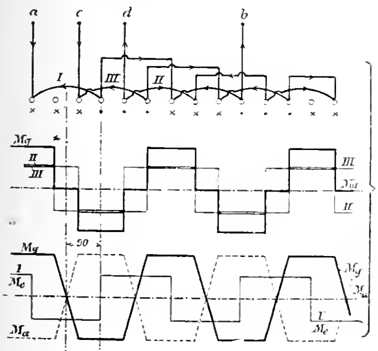

FIG. 2.—DIAGRAM OF WINDINGS DEVELOPED.

Direct-Current Machines.—SCHULZ.—An article on the progress made on the design of direct-current dynamos. While formerly the appearance of sparks at the commutator was often considered to represent the limit of load, the limit is now mostly found in the heating since it is possible to assure good commutation quite successfully. There is now a tendency to provide good ventilation in order to also counteract the heating. The author gives several formulas which have been proposed for the choice of the armature dimensions. Concerning the number of poles he says that more-pole machines are always preferable to machines with few poles and the latter should only be chosen if the calculated air-gap with the more pole arrangement would lead to mechanical difficulties. The price of the magnet yoke, the magnet coil copper and the armature copper is lower with a four-pole machine than with a two-pole machine, while the magnet cores and pole shoes are more expensive for the four-pole machine; but in the latter case the difference is insignificant. He then discusses the various formulas given for determining the commutation from the reactance voltage, but says that the reactance voltage alone should not be considered the only point upon which good commutation depends. There is also distortion of the field, and even with a good reactance voltage it may cause an impermissible brush displacement on account of field distortion. The use of sheet iron for the magnets or at least for the pole shoes has largely increased. This is probably due mainly to a better understanding of the importance of a correct pole shoe shape. The cost of manufacture is not very different, since sheet iron is cheaper than cast steel. The author concludes with some remarks on standardization.—*Elek. Anz.*, February 14.

REFERENCES.

Speed Regulation of Induction Motors with Commutator.—LATOUR.—While it is known that the use of a commutator with alternating-current machines enables one to operate them without phase difference at normal load with perfect commutation, and to start single-phase motors with a good torque, the author endeavors to show mathematically that it also enables one to change the speed of induction motors without influencing the efficiency. The author gives the theory for shunt and series polyphase motors and makes some brief remarks on single-phase motors.—*L'Eclairage Elec.*, February 27.

Single-Phase Commutator Motors.—BLONDEL.—In a continuation of his very long serial on the theory of single-phase commutator motors, the author begins to discuss analytically and with the aid of diagrams the theory of the repulsion motor with supplementary shunt excitation.—*L'Eclairage Elec.*, February 27.

Single-Phase Commutator Motors.—EICHBERG.—The first part of a complete illustrated translation of the long paper of Eichberg read before the Berlin Electrical Society and abstracted recently in the Digest.—Lond. *Elec. Eng.*, February 26.

LIGHTS AND LIGHTING.

Mercury Vapor Lamp.—BODENSTEIN.—A brief account of experiments with a mercury vapor lamp made of fused quartz (of Heræus). The lamp is built in form of an H and the arc plays through the nearly horizontal tube between the mercury surfaces in the two vertical arms. For connections iridium wires are used. A small tube at the side of, and communicating with, one vertical tube of the H lamp is filled with mercury and is electrically heated. The mercury evaporates and the vapor presses the liquid mercury through the nearly horizontal tube so far that it makes a short circuit with the mercury in the other vertical tube. An automatic device then disconnects the heating current. The mercury vapor in the side tube condenses again and sucks the liquid mercury back and the arc is lighted through the nearly horizontal tube. Concerning the energy consumption it is said that by a rough estimation the lamp gives for 2 amperes at 100 volts the same illumination as an arc between carbon switch 20 amperes and 50 volts, but is much more constant. In spite of its green color, the light is rich in ultra-violet rays and for this reason suitable for many special scientific investigations. At the beginning of the use of the lamp a strong smell of ozone was observed.—*Zeit. f. Elektrochemie*, February 19.

POWER.

Austrian Transmission Plant.—BOEMENDAL.—A detailed and profusely-illustrated description of the water power plant using rapids of the River Mur. There are four turbine-driven, 500-kw generators with a power factor of 0.85. The generating voltage is 1,500. For transmission the current is transformed up to 21,000 volts by means of three 650-kw sets of transformers. Single-phase transformers are used in order to secure the advantage of the delta connection, so that should one transformer get out of order the other two could keep up the supply, working in V form under an overload for which they are designed. Most careful attention has been given to the arrangement of the ovehead conductors. These consist of three copper wires, 38.7 sq. mm. (0.06 sq. in.), carried on porcelain insulators. The latter have a triple bell; they are fixed on their wood supports with the interposition of porcelain studs screwed in hardwood, fully impregnated with paraffin. The testing of the insulators has been carried out with great care, using a 120,000-volt pressure, the tests having been made, as far as practicable, by placing the insulators in service conditions and under a water spray. The three wires are mounted in a 3-ft. 3⅜-in. equilateral triangle. One insulator is at the top of the post, and the two others are on wood brackets. Every post is fitted with a lightning rod suitably connected to earth, and at about every 1,000 yards there are provided lightning arresters with magnetic blow-out devices. An incident is recorded which occurred when the line first started working. The first section of the line was first set alive as far as the nearest switch and the tension was gradually raised up to 24,000 volts, the section remaining under these conditions for thirty minutes. This was effected in the case of four consecutive sections with satisfactory results. When, however, the fifth section was connected up, and the pressure had risen to over 18,000 volts, a short-circuit was produced and the 21,000-volt fuse blew. As a matter of fact, this section bore the 18,000-volt pressure for an indefinite time; but on its being gradually raised by only 50 volts the short-circuit occurred. The cause of this, after rather lengthy investigations, was found to be the cracking of an insulator, producing thereby the short-circuit, although the crack did not go through the whole thickness of the porcelain. The experiments were further carried on, and a series of critical limits of pressure were tabulated; at these limits the very smallest defects in the porcelain insulators are of importance, and may lead to injurious results. The long-distance line has a length of 20 miles, and is divided into eight sections, in order to more easily detect any defects and to cut out any section without stopping the whole plant.—Lond. *Eng'ing*, February 26.

Electric Power in Workshops.—IRWIN.—A paper in abstract read before the Rugby Engineering Society, in which he describes the power supply of the Niclausse boiler works of Willans and Robinson. When these works were being planned, the question of the adoption of direct or alternating current came up. In some respects the alternating current could claim superiority for works of this kind. Since the load was principally made up of motors driving tools and machines at constant speed, induction motors would have been suitable. Other considerations, however, among them that of cost, decided in favor of the direct-current supply. The main supply is at 410 volts from three shunt-wound generators, two of which are 220-kw machines and one a 90-kw machine. Working in parallel with the generators and in conjunction with an automatic booster is a battery of 197 cells. The cells are able to give a discharge of 125 amp. for three hours. Instead of the ordinary three-wire system, with equal voltage on each side of the middle wire, a "balancer" is provided which has two windings and two commutators on the same armature core, and gives 308 volts on one side and about 102 volts on the other. As there is very little load on the 300-volt circuit, the function of the machine is not to balance so much as to give a supply at 100 volts, and it is referred to as a rotary transformer. The reason for this division is, in the first place, to supply 100-volt current for arc welding; secondly, to allow of single arc lamps being run where two lamps would not be necessary; thirdly, to allow, where required, of a large range of speed. Thus, by keeping the field of the motor across the 400-volt circuit and by putting the armature successfully across the 100, 300 and 400-volt circuit, the speed will vary in the ratio of one to three to four. Intermediate speeds can be obtained by field regulation if necessary. The main arc lighting is carried out from the 400-volt circuit, partly by enclosed and partly by open-type lamps. The enclosed lamps are run four in series, and the open-type lamps eight in series. All these lamps are provided with external automatic cut-outs and substitutional resistances. One of the problems to be solved was that of driving the rolling mill and the tube draw benches by means of a motor, without disturbing the arc lamps running off the same set of mains. The motor has a capacity of 275 hp and is compound-wound and drives, by means of ropes, an eight-inch diameter shaft to which the mill and draw benches are coupled. The rope pulley on the shaft is about 15 tons in weight and, therefore, acts as a fly-wheel governor.—Lond. *Elec.*, February 19.

Gas Engines in a Metallurgical Plant.—LANGTON.—An illustrated description of the power plant of the Montezuma Copper Company at Nacozari, Sonoro, Mexico. The power house contains eight gas engines each being connected to a 65-kw direct-current generator. The generators are run in parallel and the current is distributed at 250 volts to some 40 different motors, scattered about the works and ranging in size from 5 to 175 hp. Arc and incandescent lamps are operated from the same circuits as the motors. Producer gas is used and the methods of making the gas either from coal or wood (the latter being the most novel feature of the plant) are described in detail, and the analysis of the gas produced is given. The paper is concluded by some remarks on the use of gas engines in general, and it is pointed out that the most economical capacity of a gas engine is its absolute maximum capacity and in order to allow for variations which are inevitable even under the best conditions of commercial working, the maximum capacity should be discounted about 15 per cent. to get a figure that may be called maximum commercial capacity. This commercial maximum capacity should equal the peak of the load curve. With a very variable load, therefore, an engine capacity is required greatly in excess of the average power demand. This disadvantage counterbalances the advantage of the ease with which gas may be transmitted to scattered gas engines without loss. The author thinks that in most cases the balance of advantage is found to be on the side of a central power house generating electrical energy from gas engines together with electric distribution to motors.—*Electrochem. Ind.*, March.

Electric Haulage in Metal Mines.—CLARK.—A paper in which the author states that the use of electricity for mine haulage has materially cheapened the cost of production; from data compiled at various mines the cost per ton of hauling coal is 50 to 75 per cent. below mule haulage, according to the situation of the mine, the grade of slope and the distance hauled. The trolley system of haulage has not been extensively used in metal mines. It is particularly adapted to long "tunnel" systems through which is hauled the ore from a number of properties. The conditions of haulage in a metal mine are radically different from those found in coal mines in which a locomotive is required which is very low, but without restriction as to width. The ordinary adit driven to tap metalliferous veins has ample height for any locomotive now on the market, but is usually restricted as to width. Some notes are given on the draw-bar pull required and the influence of grades, and the haulage system of the United Gold Mines Company, of Victor, Colo., is described. It is the only electric mine haulage system in use in the Cripple Creek district. An 8-ton locomotive is used with a draw-bar pull of about 3,500 pounds and a speed of 15 miles per hour. The machine is equipped with a single high-speed motor placed in the center and on the top of the frame, and the motor shaft connects to the drivers by a chain of gearing. The brake is applied directly to the motor shaft. The trolley is hung in the center of the track and has caused no inconvenience. From a water power plant three-phase currents are transmitted a distance of 12 miles at a pressure of 13,000 volts, the frequency being 30 cycles. At the sub-station step-down transformers and rotary converters change the current to 550 volts direct current to the trolley.—*Eng. & Min. Jour.*, February 25.

REFERENCE.

A Swiss Hydroelectric Plant.—COLLISCHONN.—The first part of a profusely-illustrated description of the Kubel water power plant situated at the juncture of the rivers Sitter and Urnaesch. The present installment describes the hydroelectric plant, for which a basin is provided to store enough water so that even in summer time, should new water cease to come, the plant would be able to give for three weeks daily 20,000 hp-hours.—*Elek. Zeit.*, February 25.

TRACTION.

Electric Mountain Road.—HERZOG.—The first part of an illustrated description of the electric railroad from Freiburg to Anet in Switzerland. The length of the road is 32 km. While the third rail is used along the road, the overhead trolley wire is employed in the stations, to prevent accidents. A central station in Freiburg provides 8,000-volt, three-phase currents, which are transmitted to two sub-stations containing motor-generators for producing the 750-volt direct-current supply to the line. The capacity of each sub-station is sufficient to give the energy required by one train. Since the average power required by a train is 150 hp, each sub-station contains a motor-generator of this capacity, together with a storage battery of sufficient capacity to furnish the power required beyond the average.—*L'Eclairage Elec.*, February 27.

Electric Railway in the Isle of Man.—A description of this line which is largely a summer road and has recently been thoroughly reconstructed. A short description is first given of the original plant, which used both water and steam power for generating electricity. The chief work in the reorganization has been in centralizing the power supply. The new generating plant, consisting of 300-kw, 7,000-volt generators, has been installed with three sub-stations containing 150-kw rotaries.—*St. R'y Jour.*, March 5.

REFERENCES.

Alternating-Current Traction.—BELL.—A review of the demand for an alternating-current railway motor. He points out that polyphase motors are not satisfactory, principally because they require two trolley wires, and because they do not have sufficient torque at starting. The writer then discusses the two types of single-phase motors which have been placed on the market, one represented by the Westinghouse and the Finzi motor, the other the repulsion motor as built by the General Electric and other companies.—*St. R'y Jour.*, February 27.

Single-Phase Traction.—EICHBERG.—The first part of a paper read before the Vienna Electrical Society. The author discusses the various types of single-phase motors, giving the characteristic features of the Winter-Eichberg motor, the series motor, the repulsion motor and comparing their relative advantages.—*Zeit. f. Elek.* (Vienna), February 28.

Electric Mine Locomotives.—AFFELDER.—A fully illustrated article on traction, third rail and sprocket locomotives, their development and the conditions to which they are adapted. He thinks that the third-rail haulage system is not a competitor of the traction or trolley system, but rather one to be used when adverse grades make traction haulage impracticable. The third-rail locomotive will continue to become a decided competitor of rope haulage and as such will probably produce its best results.—*Mines and Minerals*, March.

Light Railway.—An illustrated description of the Barking-Becton light railway, which is 1.3 miles in length, the trolley system being used. Owing to the fact that the line carries very few passengers other than workmen employed at the Becton gas works, the load is a very variable one and the system of split shifts has been adopted. In passing over a river it was stipulated that some arrangements would be made whereby it was impossible to open the bridge whenever a car was within a hundred yards on either side. To comply with this requirement, certain interlocking devices were designed which are described. Electric power is used for opening the bridge.—Lond. *Elec.*, February 26.

INSTALLATIONS, SYSTEMS AND APPLIANCES.

Voltage Regulation in Alternating-Current Systems.—H. S. MEYER.—A continuation of his illustrated paper, the first part of which was abstracted in the Digest last week. The supply of incandescent lamps demands an almost perfect regulation, since changes—even if only of the order of 2 to 3 per cent.—will have serious consequences for the life and efficiency of the lamps, and, therefore, all ordinary generators, in order to supply satisfactorily a lighting system, need careful attendance at the switchboard. Concerning an induction motor load, he says that under full load and at standard speed the power factor should lie, with a well-designed polyphase induction motor, between 90 and 95 per cent., but when running partially loaded or with slow-speed motors or single-phase machines figures much below those mentioned must be expected, and it may be assumed that motors when used on a supply system will introduce lagging currents amounting to about 60 per cent. of the rated load current of the motor load. By combining separately the wattless and the energy current thus introduced with the corresponding currents of the rest of the load, the resultant power factor is obtained upon which the regulation of the generator depends. A diagram if given to show the influence which a large induction motor starting under heavy load will have on the generator regulation. The author points out that it is wrong and unfair to restrict the starting current of an induction motor to a certain percentage of its full-load current. Such restriction affects a 10-hp motor in the same way as a 1-hp motor, although the disturbances in the voltage regulation in the former case would be ten times as large. Furthermore it gives the advantage to the poorer motor, as this will have a larger full-load current, due to the lower apparent efficiency. The correct way is to either place a limit on the amount of current which may be taken at starting, or, still better, vary the restrictions for each size and grade of motor. The power factor of a synchronous motor can be made leading or lagging at will by varying the strength of the field excitation, so that the synchronous motor offers a simple method of compensating for the effects of inductive loads in other parts of a power system. If a synchronous motor is over-excited so as to take a resultant current 5, 10 or 15 per cent. greater than its normal load current, it is capable of compensating for a lagging current 32, 46 or 57 per cent. as great as its normal load current. The most efficient way of using such machines as "rotary condensers" is by loading the same with 71 per cent. of the rated output mechanically, and then raising the excitation until the resultant current is equal to the rated current. A leading component is then obtained of the same magnitude as the energy component. In spite of such advantages as may be obtained by controlling the power factor, a more general introduction of the synchronous motor for power work is greatly hampered by their inferiority in regard to starting torque. Too many synchronous motors on one system may also lead to trouble, as they are extremely sensitive to any fluctuations in the voltage or impressed frequency as may be caused by the prime-movers.—Lond. *Elec.*, February 26.

Frankfort.—An extract from the annual report of the Frankfort-on-Main municipal lighting and traction plant, which is particularly interesting from the fact that a 5,000-hp steam turbine has been in use since August, 1902. This turbine operates 17 hours a day and is guaranteed for 2,600 kw single-phase current. The main power station also contains four 552-kw turbines and four 1,033-kw turbines. The coal required per kw-hour during the year reported was 1.63 kg. and the cost of coal per kw-hour was 0.75 cent.—*St. R'y Jour.*, February 20.

Dangers of Electricity in Mining.—A very long serial with many illustrations. The direct danger of touching a conductor which carries current is enhanced by the particular conditions of mining and has already caused some accidents, on the other hand the more indirect dangers, due to fire and explosion, caused by electric sparks, etc., have caused so far very few accidents, mainly for the reason that in installing an electric plant in a dangerous mine, great and sometimes even exaggerated precautions are taken. The various possibilities of danger are discussed in detail and methods which have been devised for preventing them are described, together with a general account of the arrangements of electric plants in mines. The serial is to be concluded.—*Glückauf,* January 30; February 6, 13, 20, 27.

Electric Installation on Board Ship.—LEBLOND.—A continuation of his article on electric installations on board warships. In the present installment the author deals especially with the methods used in wiring and the insulation of the conductors.—*L'Ind. Elec.,* February 25.

Ignition of Gas Engines.—SOULIER.—An illustrated description of various types of magneto electric machines for producing the sparks for ignition of gas engines, especially in automobiles.—*L'Ind. Elec.,* February 10.

ELECTRO-PHYSICS AND MAGNETISM.

The Structure of the Atom.—J. J. THOMSON.—A paper in the first part of which the author discusses a mathematical problem suggested by the view that the atoms of the elements consist of a number of negatively electrified corpuscles enclosed in a sphere of uniform positive electrification. The problem discussed by him is the motion of a ring of a given number of negatively electrified particles placed inside a uniformly electrified sphere. The general equations are first developed and are then applied to the cares of two, three, four, five and six corpuscles and the mathematical conditions for the stability of a ring containing more than six corpuscles are developed. The author then applies his mathematical results to the hypothesis that an atom consists of a number of corpuscles moving about in the sphere of uniform electrification, and shows that if the corpuscles are constrained to move in one plane they will arrange themselves in a series of concentric rings, while when they can move about in all directions they will arrange themselves in a series of concentric shells. The author adds the extremely interesting proof that if we assume such a structure of the atom it will have properties analogous in many respects to those possessed by the atoms of the chemical elements and that in particular the properties of the atom will depend upon its atomic weight in a way very analogous to that expressed by the periodic law.—*Phys. Mag.,* March.

Electro-Capillarity.—CHRISTIANSEN.—An account of experiments in which the author studied some peculiar movements of mercury in

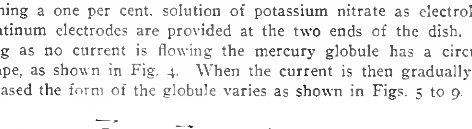

FIG. 3.—ELECTRO-CAPILLARITY.

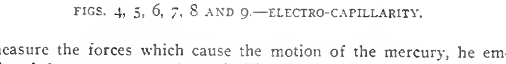
an electrolyte, due to electro-capillarity. As seen in Fig. 3, a globule of mercury was placed in a watch glass at the bottom of a dish containing a one per cent. solution of potassium nitrate as electrolyte. Platinum electrodes are provided at the two ends of the dish. As long as no current is flowing the mercury globule has a circular shape, as shown in Fig. 4. When the current is then gradually increased the form of the globule varies as shown in Figs. 5 to 9. To



FIGS. 4, 5, 6, 7, 8 AND 9.—ELECTRO-CAPILLARITY.

measure the forces which cause the motion of the mercury, he employed the arrangement shown in Fig. 10, in which a tube is provided at the two ends with two wider tubes to contain the electrolyte. A mercury globule is placed in the middle of the tube. The tendency of the globule to move on account of the flow of the current is counteracted by placing the tube in an inclined position as shown in the figure. A thrd experiment was made with mercury drops, falling through an electrolyte. As long as there is no current the drops fall plumb, but when an electric current is passed through the electrolyte

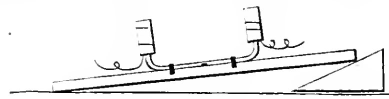


FIG. 10.—ELECTRO-CAPILLARITY.

the drops are deviated from their plumb course towards the negative pole. The deviation is approximately proportional to the current and also depends upon the electrolyte. The author explains these phenomena by the double-layer hypothesis.—Lond. *Elec. Rev.,* February 19.

Photographic Action of Radium Rays.—SKINNER.—Since a photographic plate by exposure to radium rays is affected in such a way that the plate develops similarly to its development after its exposure to light, the author has made experiments to find whether the actions are the same in both cases. His results seem to indicate that only slight differences occur in the early stages of development. For prolonged exposure he reaches the following conclusions: The density of the image produced on a plate by exposure to radium rays (β and α) increases to a critical value and then decreases, first rapidly and afterwards very slowly, until a time is reached when the image is totally reversed. Spark images are at first obliterated by radium rays which do not cause such a great density as that of the spark images obliterated. With prolonged exposure, radium rays reverse spark images.—*Phil. Mag.,* March.

REFERENCES.

Light and Electric Waves.—BRAUN.—An account of experiments in which he produced with ordinary light waves the effect produced by Hertz with a grating of parallel wires which is found to reflect electric waves vibrating in the plane parallel to the wires while it freely transmits those waves which vibrate at right angles to the wires. In his experiments he used wires disintegrated on a glass plate by means of a powerful electrostatic discharge.—*Sitzungsber. Akad. Wiss., Berlin,* January 21; abstracted in Lond. *Elec.,* February 19.

N-Rays.—BICHAT.—An account of experiments made to find an explanation for the apparent anomaly that N-rays, being a form of radiation, may be "conducted" by a wire. The conduction is a case of successive reflection. Light may be similarly conducted along a curved glass tube. The transmission is really due to the wire and not to the medium in which it is placed. In order that the conduction may take place, it is necessary that the material of the wire should itself transmit N-rays.—*Comptes Rendus,* February 8; abstracted in Lond. *Elec.,* February 26.

Magnetic Effect of Convection Currents.—GUTTON.—A description of a new method of proving the magnetic effect of convection. If a luminescent screen is placed on an earthed sheet of lead and an electrified ebonite rod is put underneath, then as long as the rod is at rest it exerts no influence; but if it is revolved about its own axis, the luminescence becomes temporarily greater. An unelectrified rod has no such action.—*Comptes Rendus,* February 8; abstracted in Lond. *Elec.,* February 26.

ELECTRO-CHEMISTRY AND BATTERIES.

Constitution of Salt Solutions.—ABEGG.—Hittorf has already shown long ago that cadmium chloride must contain in solution, besides the simple cadmium and chlorine ions, also complex ions formed by a combination of cadmium chloride with chlorine ions. From experiments made by Labendzinski, the present author concludes that such complex ions must be assumed to exist to a far greater extent than has been assumed to be the case, in acetates,sulphates and chlorides, and to a smaller extent in nitrates; the metals, the salts ofwhich were examined being zinc, cadmium, iron, cobalt, nickel, lead and copper. To the existence of such complex ions the author attributes the reason of the well-known disagreement between theory and practice in the case of Ostwald's law for the relation between conductivity and dilution.—*Zeit. f. Elektrochemie,* January 29; abstracted and commented upon in *Electrochem. Ind.,* March.

UNITS, MEASUREMENTS AND INSTRUMENTS.

Direct-Reading Ohmmeter.—SACK.—An illustrated description of a direct-reading ohmmeter of Siemens-Halske, which consists essentially of a milliammeter with revolving coil. With some storage cells and the unknown resistance to be tested it is connected in series. In order to get a suitable scale, that is, one with approximately uniform divisions, the pointer is arranged to be at open circuit beyond the scale and to enter the scale only when the tested resistance is smaller than the maximum ohms for which the instrument is calibrated. In order to prevent that when opening the circuit and pointer comes back with too high a speed to its zero point, arrangements are made so that when the tested resistance is disconnected, the instrument is at once connected to another resistance which corresponds to the maximum ohms for which the instrument is calibrated. The pointer goes to the beginning of the scale and the circuit may then be opened without danger. In order to make the reading independent of the voltage of the battery, a magnetic shunt is provided which by means of a screw can be pushed more or less over the poles of the magnet so as to vary the magnetic field strength at will.—*Elec. Rundschau*, February 15.

MISCELLANEOUS.

Electrical Engineering in Russia.—An account of the proceedings of the third Russian Electrical Congress which was held in St. Petersburg at New Year, more than 500 members being present. Kowalewski spoke on the utilization of the water powers. Nearly nothing has been done in this regard in Russia; while in Germany water falls are available to the extent of not more than 17,000 hp, in Russia up to about 15,000,000 hp are available. The congress adopted a resolution that the right of developing the power of rivers for electrical purposes belongs to the state, which may either develop the power itself or may sell the franchise to companies or private parties, which thereby obtain the right of expropriating the ground necessary for the plant. Lubenski discussed the application of electric traction on the Siberian Railway and thought that especially in Central Siberia for a length of 900 km. the use of electric traction would be profitable since in winter there are difficulties with steam traction. In the discussion which followed the economy of this project was questioned, since ice formation on the trolley wire might offer a great difficulty. Graftio spoke on the economical results of electric traction on railroads and the congress adopted a resolution in which the departments of commerce and finance were requested to have an investigation made of the utilization of the water falls of the Caucasus and near the Black Sea in order to electrify the railroads in the neighborhood. Kohan reported on the project of electric tramways in St. Petersburg. While no decision has yet been reached concerning the method of current supply to the cars, the general plan has been laid out of the road. The capacity has been calculated so that 264,000,000 passengers can travel per year. The length of the lines will be 315 km. A central station of 18,000 kw, with 6,000-volt, three-phase currents and eight sub-stations for 600-volt direct current have been projected, but it is not yet decided whether water power or steam engines or steam turbines shall be used. Popow spoke on wireless telegraphy. There are now in the far east of Russia 50 stations and it is possible to transmit messages from ships to the coast for the distance of 190 km.—*Elek. Zeit.*, February 18.

Naval Wireless Telegraph School.

It is stated that the Navy Department is making preparations to transfer the wireless telegraph school for enlisted men from Newport, R. I., to the Navy Yard at New York.

New Books.

HIE EUROPA! HIE AMERIKA! By Julius H. West. Berlin: Siemenroth. 55 pages. Price, 1 mark.

The author of this book has endeavored to lay bare the reasons for America's economic superiority in the markets of the world. While much of his reasoning is not new, his book is very interesting because he discusses the subject from the standpoint of actual experience. Mr. West visited the United States on two occasions to study manufacturing methods. He himself spent several years in actual machine shop practice before becoming an editor of the *Elektrotechnische Zeitschrift*. His comparisons between European and American shop practice are very interesting. While in Europe the working man is not encouraged to make any improvements and is treated as an inferior, Mr. West found that in the United States every inducement is offered to the employee to make improvements resulting in lower cost of product. He earnestly recommends European manufacturers to change their present policy and follow the best American methods.

A Motor Driven Coin-Counting and Wrapping Machine.

BY EDWARD VAN WINKLE.

The accurate counting and the proper handling of a large number of coins is a heavy task and necessitates the employment of clerks and others for the purpose. Such persons, unless specially skilled in counting, often find it difficult to continue the work for any length of time without great fatigue, while errors are likely to arise because of miscount. A machine for this purpose is illustrated here-

FIG. 1.—MACHINE IN OPERATION.

with, which counts and wraps at the rate of seven coins a second or 420 coins (8 to 12 bundles) in one minute.

The immense saving of labor is at once realized by making a comparison to hand labor, which can as a maximum, provided no error in count occurs, count and wrap only one bundle per minute. This machine therefore will do the work of from eight to twelve men, without taking into consideration the loss in time if a miscount is found, with hand labor. The above speed is limited only by the examination of the coins by the operator, as they are fed into the machine from the table upon which they were first deposited. Experience has proven that 300 coins examined per minute is a safe and conservative limit which should be expected from the average operator.

It does not require any knowledge of machinery to run and operate the machine, as a small boy has proven to be as capable as any operator. The machine being entirely automatic, requires no attention.

By referring to the illustrations, Fig. 1 represents the machine in operation. Fig. 2 shows the machine in closed position with the coin conduit and box removed and table top swung around taking its position directly over the machine so as to protect it when not in use. A cover or hood may then be thrown over the machine to keep out the dust. Fig. 4 shows the product of the machine with the ends crimped like a cartridge, exposing the coin.

The coins are first deposited upon the table attached to the machine and then passed under the gauge by the operator, who rejects any mutilated or counterfeit pieces. They then drop into the conduit and are conducted by gravity to the machine, where they are each taken up separately regardless of thickness or diameter, advanced by the reciprocating push bar and assembled in a row ready to be wrapped. After the requisite number of coins are advanced, the registering of the final coin of the bundle sets in operation the wrapping mechanism, which is normally inoperative. The bunched coins are then transferred from the buncher to the wrapper by means of the holder, which then returns to its original position, ready to receive the coins of the subsequent bundle.

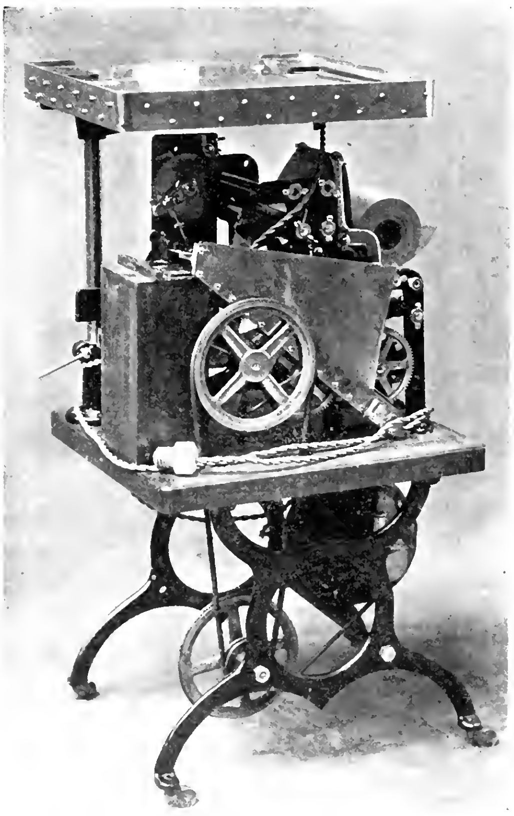

FIG. 2.—MACHINE IN CLOSED POSITION.

The bunch of coins while thus being transferred to the wrapping mechanism carries with it the end of the paper which has been fed in their path during the wrapping of the preceding bundle. Simultaneously, the lower coin roll is raised, forming a pocket with the two upper rolls into which the bunch of coins is carried, and the end of the paper is fed by friction between the three driving coin rolls and around the bundle of coins. The wrapper completely encircles the coins twice, giving strength and body for the crimp. The feeding of the paper around the bunch of coins tears the wrapper from the roll of paper by pulling the paper over a V-shaped knife, leaving its end, which serves for the final wrapping, cut with inwardly converging edges. The side edges of the wrapper are then turned inwardly by the crimpers, thereby drawing upon the converging edges in opposite directions and holding the final wrapping end of the wrapper closely and smoothly upon the rolled package without the aid of independent fastening, such as glue or paste.

The length of the package is determined by the thickness of the coin, which varies considerably. The crimp is always brought up tight to the coins by the crimpers, which are drawn together by means of a right and left-hand screw. When the crimp is complete the cartridge is thrown out of the machine into a box, which is detachable and may be filed away in a safe or vault, thus minimizing the labor in handling the coins. The package of coin when shot out of the machine is so securely wrapped that no one coin can be extracted without destroying the entire package, thus making it impossible to cheat the machine.

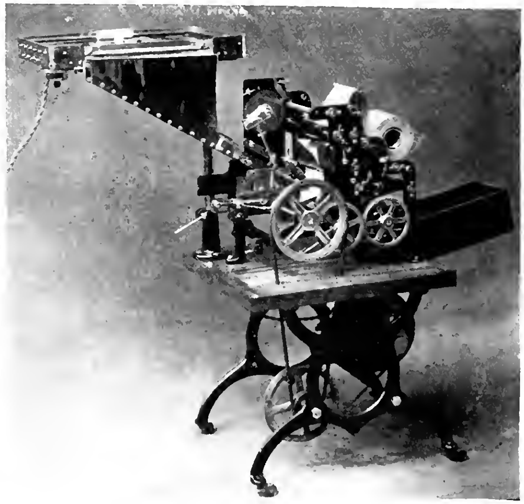

FIG. 3.—COIN-COUNTING AND WRAPPING MACHINE.

The machine is operated by an electric motor, and as it consumes but three-tenths of an ampere at 110 volts, it is easily attachable to any standard light socket by means of a connection plug. It is started and stopped by a turn of a button switch.

It will be noticed that the paper is fed into the machine from the under side of the roll, which is in plain view in Fig. 1. In this position the curl of the paper due to the roll helps the wrapping of the package and makes it possible to neatly crimp the ends, as shown in Fig. 4. If fed from above, as was the case when the machine came to attention for development, the crimper, in addition to its own work in crimping the ends of the package, had to overcome the curl of the paper, and the crimped ends were therefore an impossibility. Simple changes like the above made this machine possible.

It may be interesting to look into the history of this coin-counting and wrapping machine and its development. The writer while exhibiting of these machines at Washington, had a long talk with the Patent Examiner, who said that he could not account for the fact that the counting and wrapping of coins by machinery had not been patented before, unless the fact that inventors as a rule did not have any money to count, and consequently their minds did not run that way. As the inventor of this machine had been connected with a "penny-in-the-slot" machine company and was dependent for his living upon returns from several of these vending machines, his revenue was all in coin and he came to dislike the sight of it. He had three nail kegs in his room in which he deposited his daily collections, and perchance if he wanted to pay some bills by check, he and his family would have to stay up all night counting and wrapping these coins so that he could deposit the same in the bank.

His wife suggested in jest one evening, while his family were industriously wrapping coin in order to swell his bank account sufficiently to pay his rent, that he "invent a way to count coins by machine and thus save this distasteful hand labor." He gave considerable thought to the idea, and developed at first a crude device which he patented and afterwards found out could not be made to work. His idea was to give rotating motion to the coins by means of a loose belt, forming a pocket instead of the three rolls as now used. He had planned to shear off the paper with sharp knives and glue the paper around the coins and fold the ends, as now accomplished by hand wrapping. His original patent called for a printing device which printed on each package the face value of the coins with each wrapping. The ideas were found to be impractical, as the knife blades would dull, and if the machine was allowed to stand the

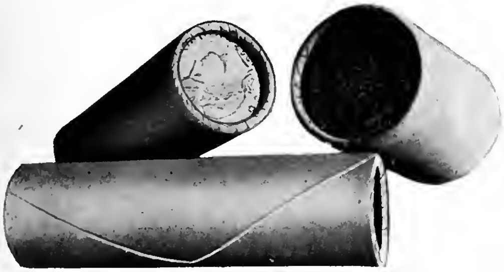

FIG. 4.—PACKAGES OF COINS.

glue would become hard and the ink dry. The loose belt would throw the coins on the floor and was found most unreliable; the idea was therefore abandoned.

With the coin exposed at each end of the package it is not necessary to print the value of the coin on the wrapper. However, when required, the printing can be done before the paper is put into the machine. Each wrapper, in length, is equal to twice the circumference of the coin which it wraps and the printing is spaced, a distance equal to half the length of the wrapper, from one end of the roll of paper to the other; thus it matters not where the wrapper is cut off the roll, as only one printing is visible on the package.

The length of the longest wrapper is 7¾ inches and is 2⅜ inches wide. This size is used to wrap twenty-five cent pieces. The length of the shortest wrapper is 4⅛ inches long and is 2⅞ inches wide and used for fifty ten-cent pieces. The economy of paper is only realized when one tries to wrap the coins by hand in a wrapper automatically cut off by the machine.

Westinghouse and the British Trade Union.

The British Westinghouse & Electric Manufacturing Company, Limited, whose colossal works at Trafford Park, near Manchester, are now in full swing, and give employment to more than 6,000 hands, have agreed to the insertion of the "fair wages" clause in their municipal contracts and are joining the British Employers' Federation, thereby undertaking to abide by the working terms mutually agreed upon by the Federation and the trade unions. Thus, once and for all, American terms of employment, which were aimed at when the company was first organized, have gone by the board.

H. S. Loud, the general manager of the Westinghouse works, according to advices received here, states that the "fair contracts" clause of the Manchester Corporation has been the main factor in bringing about the decision. The company tendered recently for a substantial contract, which was duly secured, with the tramways department of that city and at a certain stage of the negotiations the question of signing the clause came up. Practically it was a question whether the company would accept the clause or run the risk of losing a valuable contract.

The concession which the British Westinghouse people have made is the outcome of prolonged negotiations. In Pittsburg it is the custom to pay time and one-half for all overtime, and this was what the British company began to do at Trafford Park. But the British trade union rule is time and a quarter for the first two hours of overtime, time and a half for the second two hours and double time for the third two hours. The company tried to show the trade unions that the Yankee method was the more advantageous, but the unions were unconvinced and the company yielded the point.

Another dispute between the company and the unions was in reference to the working hours of the night shift, but this has been amicably settled and now that the company has accepted the terms of the "fair wages" clause the last bone of contention is buried.

Electric Power in Gold Dredging.

BY C. WESTON CLARK.

The first gold dredgers in California were operated by steam, but expensive operating made them successful only when rich ground could be worked. With cheap electric power, dredging land averaging less than 10 cents a cubic yard is made profitable. The gold-carrying soil varies from 10 to 50 ft. in depth, being a gravel deposit left in old river channels.

The two types of electric dredges which have been used secure the soil by either lifting it through centrifugal pumps or by an endless chain of buckets. The latter system seems to be the most favorable. A boat is built in a pit where it is to be operated, and the necessary machinery placed aboard. The pit is then filled with water to a depth of from 25 to 40 ft. The boats are fed by a cable about 500 ft. long, which runs from the shore to the boat. Generally these cables are arranged for three-phase, 60-cycle current standard low voltage, but one or two of the boats are fed by a 4,000-volt, four-wire cable, which is carried directly to the boat and the ore transformers placed on the boat. The lower voltage cables are rubber insulated and triple-braid water-proof. The 4,000-volt cables are leaded and armored. The transformers are sometimes placed on the boat and sometimes on a pole near the boat. Usually the latter arrangement.

The dredger digs its own channel ahead of it, depositing the soil

FIG. 1.—DREDGE "HEAD ON."

which has been worked behind it. The soil is elevated into a grizzly or similar screening device where the rocks are washed from the soil, the rocks being delivered to the carrier that deposits them out of the way behind the dredger. The soil is then washed through shakers and riffles, leaving the gold deposited on saving tables to be taken up with quicksilver, and the worked-over soil is run out at the stern of the boat. The General Electric Company, Schenectady, N. Y., has developed electric equipments for such machinery of all kinds, and the electrically-operated dredges recently equipped by that company are splendid examples of successful engineering enterprise.

A typical outfit recently sold to the Western Engineering & Construction Company for the Central Gold Dredging Company, of Oroville, consists of the following induction motors: One 50-hp motor, with controller and resistance for driving the bucket line; one 15-hp motor, with controller and resistance for operating the winches (this apparatus is for working the head lines and changing the direction of the boat to suit the work); one 40-hp motor, direct-connected to a centrifugal pump (this pump furnishes water for washing the soil); one 15-hp motor to drive the stacker or conveying belt which disposes of the stones; one 15-hp motor for operating the shaking screens; one 30-hp motor for operating the sand pump (this motor is worked occasionally when the sand accumulates too thickly at the back of the boat, and delivers it out on the rock pile through a long pipe); one 3-hp motor for operating a deck and bilge pump, used for general washing purposes. The buckets each carry 3 cubic feet of earth. A similar equipment of the chain bucket type is furnished the Butte Gold Dredging Company. This has 85 buckets to the chain, each bucket having a capacity of 5 cubic feet, and being oper-

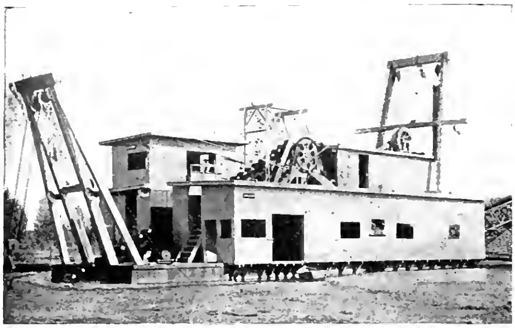

FIG. 2.—DREDGE WORKING SAND PILE.

ated at a normal speed of 22 buckets per minute. The dredge will dig from 50,000 to 75,000 cubic yards of material per month. There are some dredges using a 3½-cubic-foot bucket which will not exceed 50,000 cubic yards per month. The standard dredge, however, uses the 5-foot bucket. This dredge has a hull about 36 by 90 feet on the water line, with a draft of 5 feet. It is fitted with two spuds —one wood, 50 feet long, weighing about 10 tons; one steel, 50 feet long, weighing about 17 tons. The swing permits of a cut about 90 feet in width. The bucket line can be run continuously on any point of the controller from the third notch to full speed. The stacker is 30 inches wide and about 90 feet long.

A number of other successful installations equipped by the General Electric Company on these lines could be mentioned. Among them are plants for the Yuba Consolidated Dredging Company, the Folsom Development Company, the Boston & Oroville Gold Dredging Company, the Oroville Gold Dredging & Exploration Company, the El Oro Gold Dredging Company, and the Ashburton Mining Company. There are now about 40 dredgers working in California with more to come.

FIG. 3.—BUCKET LINE.

Portable Voltage and Series Transformers.

The ordinary equipment for making electrical measurements affords chances for error which care cannot always overcome. It is frequently impossible to have at command instruments of all the capacities required to give the best results. Readings should be taken well within the range of the instruments, upon the portion of the scale where the divisions are large and open and errors in observation not likely to occur. Even when instruments of all the desired ranges are at hand, it is still often difficult to obtain absolute accuracy and uniformity of results, owing to the variations in the different instruments which make it impossible to check up the results obtained.

In checking and testing electrical instruments with the use of the ordinary appliances, the standards often present the same difficulties and make it impossible to certify absolutely to the accuracy of the results obtained. In fact, the greater number of the errors and discrepancies in tests can be traced directly to lack of legibility of standards and to variations in the different instruments.

Manifestly, the ideal instrument either for taking measurements or for making comparisons with other measuring devices is one which will combine a great degree of legibility with a capacity for all ranges in which readings are to be taken, and any means by which these

FIG. 1.—PORTABLE TRANSFORMER.

characteristics can be imparted to the instruments now in service is of practical value.

The best method for accomplishing the desired result is by the use of transformers which will adapt the voltage or current to be measured to the capacity of the instrument to be used, adopting a ratio which will permit readings to be taken from the most legible portions of the scale. By this means any difficulty in readings is obviated, uniform accuracy at all capacities is assured, and a single voltmeter, ammeter and wattmeter will fulfil all the requirements of the most exacting service.

Portable series and voltage transformers made by the Westinghouse Electric & Manufacturing Company and shown in the accompanying illustrations are especially designed for this work. They are carefully made, the ample insulation and generous amount of iron and copper used reducing to a minimum the error of transformation. They are designed to give accurate ratios at the load which will normally be imposed on the secondary, by the ordinary type of portable instruments, the output of the voltage transformer being about .15 amp. and the maximum voltage across the secondary of the series transformer being about three volts.

The series transformer is made in two types. In one, Fig. 1, designed for primary currents up to 100 amp., the ratio is changed by plugs, somewhat as in the Wheatstone bridge. In the other type, which is designed for larger capacities, there is a circular opening through the transformer, and the conductor is passed through this opening, forming the primary. In this type the ratio is changed by the number of turns made by the conductor; passing it through the aperture once gives a ratio of 400 to 5, twice a ratio of 200 to 5, and four times a ratio of 100 to 5.

The voltage transformers are furnished in various capacities up to 750 volts primary, the standard secondary voltage at the maximum primary voltage being 150 volts. The terminals on the primary are arranged so that a number of primary voltages may be obtained, although they are not usually required in a great range of capacities, as is the case with series transformers.

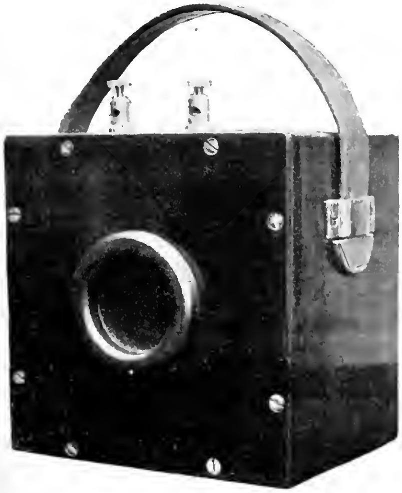

FIG. 2.—PORTABLE TRANSFORMER.

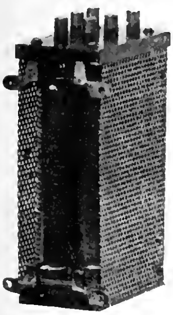
These transformers are mounted in finely finished mahogany cases with carrying handles. The terminals of the voltage transformers and the plug contacts of the series transformers are protected by a cover, which, for convenience in use, is made removable.

Quadruplex "Leak Boxes."



"LEAK" BOX.

The Ward Leonard Electric Company, of Bronxville, N. Y., is building a large number of quad. leak boxes for the Postal Telegraph Cable Company, which have the following features: The resistance consists of five Postal units (6½ in. long by 1⅛ in. in diameter) which can be readily taken out and new ones of different resistance inserted, if desired. The resistance wire is of a special alloy, which has a practically zero temperature coefficient. The resistance wire and the joint between it and the large lead wire are thoroughly covered by enamel, which hermetically seals them from the atmospheric conditions of moisture, etc.

The Postal Telegraph Cable Company has found that resistance lamps and cotton-covered insulator coils of resistance are not electrically perfect nor are they permanent, for the reason that, in the case of the lamp resistances the filament deteriorates and that even when new the resistance is variable with the temperature of the filament, due to the passage of current. In the case of the cotton-covered wires, more than one layer is necessary to obtain the proper resistance in a limited space, which leads to the result that upon the passage of current the inner layers are at a high temperature, heat from which cannot be readily dissipated, etc., and the insulation of the inner layers becomes charred and burned off. Mr. Francis W. Jones, head of the engineering department of the Postal Telegraph Cable Company, has suggested the design of these boxes and has paid particular attention to the special type terminals, which consist of nuts and washers, with the necessary lock nuts, etc., so arranged that not more than one nut can be moved at one time and when once locked can never become unlocked of itself.

Big British Westinghouse Contract.

The British Westinghouse Electric & Manufacturing Company, Limited, has recently secured the most important contract ever awarded in Great Britain for the installation of a light and power system for dock use. The value of the contract is in the neighborhood of $350,000. The Midland Railway, which operates one of the principal steam roads on the other side, is expending some $18,000,000 in the construction of docks at Heysham Harbor, Morecambe Bay, Lancashire, which will be used in connection with the company's Irish steamship service.

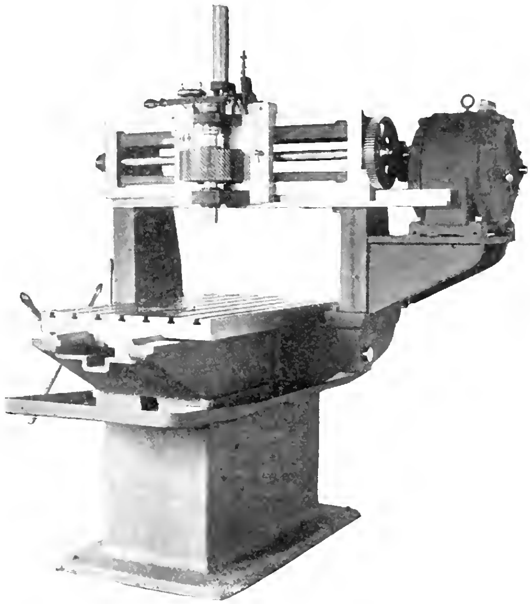
The initial equipment of the power plant will be somewhat over 1,000 hp. There will be three 350-hp Westinghouse gas engines direct-connected to Westinghouse generators of 250-kw capacity each. The gas engines will operate on Mond producer gas. There will be 500 kw more generating equipment added to the plant shortly. The cranes will be 28 in number. There will be one of 100-tons capacity, ten of 5-tons capacity, five of 2-tons capacity and twelve platform cranes.

Another interesting contract obtained by the British Westinghouse interests calls for the motor equipment for 200 additional cars for the Manchester Corporation electric traction system. Each car will have two motors of 35 hp each.

Motor Driven Profiler.

The machine illustrated herewith was built for finishing the bevel edges of irregular-shaped retort doors, and shows how readily the electric drive can be adapted to this class of tool. The spindle is driven by spiral gear and pinion from a spliced shaft and the wide face of the spindle gear permits the up and down adjustment.

The cross slide is moved by vertical rack pinion shaft contained in the right-hand upright and connected with a pilot wheel at the side of the bed. The large table is also moved by pilot wheel, the two wheels being located close together, so that all necessary movements in following an outline are controlled from one point, from which the cut can be seen at all times. The movements of the machine are by hand as is necessary in following the outline of the model.



MOTOR-DRIVEN PROFILER.

The spindle runs in bronze cap boxes and the slide is balanced and fitted with micrometer lock notch stop and screw gauge stop. The table feeds 46 in., clear height 6 to 13 in., clear width 25 in. The weight is 4,500 pounds. The maker is the Garvin Machine Company, New York.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—The market was very dull throughout the week, and the volume of business done was exceedingly small—in fact, the smallest for almost ten years. Business from commission houses was entirely lacking and the professional operations were quite insignificant. Toward the end of the week there was a little improvement in point of activity, but it was almost entirely at the expense of prices. The week was entirely devoid of any striking incidents in connection with the share list. The Steel shares were quiet and firm, and the traction group was irregular. Some weakness developed toward the close of the week in Metropolitan Street Railway, the closing price—106⅞—being 7⅛ points below that of the previous week. Brooklyn Rapid Transit lost ⅜, closing at 39½. The electric group also suffered losses, General Electric closing at 159½, being a net loss of 1½, and Westinghouse at 157, a loss of 8 points. Western Union was the exception, making a net gain of ½ point, the closing price being 88½. The curb market was somewhat irregular and reactionary, in sympathy with the Stock Exchange, and the volume of business was small. Electric Boat preferred made a net gain of 2 points, closing at 54, ex-dividend 2 per cent. Following are the closing quotations of March 15:

WESTERN UNION FIGURES.—The Western Union Telegraph Company reports for the quarter ended March 31, 1904 (partly estimated):

	1904. (Estimated.)	1903. (Actual.)	1902. (Actual.)	1901. (Actual.)
Net revenue	$1,750,000	$1,842,269	$1,592,218	$1,504,226
Bond interest	286,300	286,300	254,770	239,040
Balance	$1,463,700	$1,555,969	$1,337,448	$1,265,186
Dividends	1,217,017	1,217,014	1,217,008	1,217,001
Surplus	$246,683	$338,955	$120,440	$48,185
Previous surplus	14,360,346	12,176,386	10,209,866	8,964,710
Total surplus	$14,607,029	$12,515,341	$10,330,306	$9,012,895

The above partly estimated statement gives the approximate figures for the nine months of the fiscal year (July 1 to March 31) as compared with the actual figures of the three preceding years:

	1904.	1903.	1902.	1901.
Net revenue	$6,007,256	$6,206,773	$5,399,852	$4,922,812
Bond interest	858,900	791,400	737,810	717,120
Balance	$5,238,356	$5,415,373	$4,662,042	$4,205,692
Dividends	3,651,051	3,651,035	3,651,022	3,651,002
Surplus	$1,587,305	$1,764,338	$1,011,020	$554,690
Previous surplus	13,010,724	10,751,003	9,319,286	8,458,205
Total surplus	$14,607,029	$12,515,341	$10,330,306	$9,012,895

BROOKLYN RAPID TRANSIT.—The statement of Brooklyn Rapid Transit for the calendar year 1903 showed a surplus after charges of $1,138,225, compared with a surplus of $964,878 for the fiscal year ending June 30, showing an increase of $173,347, or 17.9 per cent. The surplus for the calendar year is equal to 2.5 per cent. on the $45,000,000 stock. The following table compares operations of the calendar year and the fiscal year 1903:

	Cal. year.	Fiscal year.	Increase.	Per cent. inc.
Gross	$14,025,825	$13,280,321	$745,504	5.6
Expenses	8,392,607	7,931,079	461,528	5.8
Net	$5,633,217	$5,349,242	$283,975	5.3
Other income	207,512	277,493	*69,981	*2.5
Total net	$5,840,739	$5,626,735	$214,004	3.8
Charges and taxes	4,702,513	4,661,857	40,656	0.8
Surplus	$1,138,225	$964,878	$173,347	17.9

*Decrease.

The increase in gross for the six months is proportionately less than the increase during the last fiscal year, which was 6.15 per cent. The operating ratio is 60 per cent. of gross earnings, compared with less than 50 per cent. for Manhattan and Metropolitan.

FAIR HAVEN TROLLEY DEAL.—The basis of the merger of the Fair Haven & Westville Trolley Company with the New York, New Haven & Hartford is understood to be the exchange of 50-year 3½ per cent. debentures for the Fair Haven & Westville stock, the latter being taken at a valuation of $50 for each share of par value of $25. The shareholders of the Fair Haven & Westville thus get 7 per cent. on the debentures in place of the present 5 per cent. dividend on stock. The merger will call for the issue of about $9,600,000 of New Haven debentures to take up the outstanding trolley stock or stock to be created April 1. By the merger the New Haven obtains about one-fifth of the whole trolley mileage in the State of Connecticut. This trolley road is the second largest single system in the State of Connecticut, and for a time was considered as a probable nucleus of an electric system between New York and Boston, paralleling most of the New Haven. Its purchase now by the New Haven will prevent any such scheme. Following the acquisition of the Fair Haven & Westville comes the report that the New Haven is negotiating to buy the Connecticut Railway and Lighting Company's lines in Connecticut, owned by the United Gas Improvement Company of Philadelphia.

NEW WESTERN ELECTRIC FACTORY.—Note has been made from time to time of the large new Western Electric factory in the suburbs of Chicago. It is said that one of the principal objects of the Western Electric Company in establishing a large factory and warerooms in the suburban district is to provide space for a large supply department sufficient to supply all the Bell telephone companies of the United States with material at the lowest price and to carry on hand large stocks of the standard goods, thereby obviating the necessity of the various companies carrying a larger stock of supplies than that actually needed. This massive storehouse and purchasing agency will be in charge of a competent person, who will do the buying for all the Bell telephone companies of the country. At present it is estimated that the several companies of the country have invested in unused supplies at least $10,000,000; under the new arrangement this can be reduced from 50 to 75 per cent. By purchasing in large quantities and distributing as wanted considerable money could be saved. This plan will, it is asserted, be put into operation as soon as the buildings are completed.

FEDERAL TELEPHONE.—The appended statement shows comparative earnings of eight of the subsidiary companies of the independent Federal Telephone Company for the months of January, 1903, and 1904. The companies included in the statement are the Cuyahoga, Findlay, Fostoria, Youngstown, Zanesville, Lancaster, Massillon and Stark County:

	1904.	1903.
Gross	$46,559.89	$44,594.44
Net	21,730.35	19,772.09
Surplus	8,590.75	7,722.23

ELECTRICITY FOR MEXICAN STEAM ROAD.—Mexico City advices state that the Mexican Railway has applied to the Secretary of Public Communications for the necessary permission to establish electric traction on the section of its road known as Las Cumbres de Maltrata, where the heavy grade requires two locomotive to haul an ordinary passenger train. The current will be generated at a large fall on the Atoyac River. The government authorities have commissioned Armando Santa Cruz to examine this waterfall and report as to the electric power it can produce.

DIVIDENDS.—The Otis Elevator directors have declared the regular quarterly dividend of 1½ per cent. on the preferred stock and a dividend of 2 per cent. on the common. The directors of the Safety Car Heating & Lighting Company have declared the regular quarterly dividend of 2 per cent. and an extra dividend of 1 per cent., payable April 1. The directors of the United Traction & Electric Company of New Jersey have declared the regular quarterly dividend of 1¼ per cent., payable April 1. Books close March 15 and reopen April 2. Westinghouse Air Brake directors have declared the regular quarterly dividend of 2½ per cent. and 2½ per cent. extra, payable April 11. The previous extra dividends were 3½ per cent. The regular quarterly 1 per cent. dividend on International Steam Pump common is payable April 1.

J. A. FAY & EGAN.—The annual report of the J. A. Fay & Egan Company shows net earnings of $324,000, with a surplus of $172,000, for the year after all dividends and charges. These figures represent the largest year's business in the history of the company. Fred. T. Egan has been elected a director of the J. A. Fay & Egan Company in place of Albert N. Spencer, who retires as director and second vice-president. The following were elected officers of the company: Thomas P. Egan, president; S. P. Egan, vice-president; W. M. Green, secretary; A. A. Faber, treasurer; Joseph Rawson, F. H. Simpson, Rudolph Klybolte, L. G. Robinson, J. E. Bruce, W. H. Doane and Fred. T. Egan additional directors.

NEW "SOO" COMPANY.—It is stated officially that the Consolidated Lake Superior reorganizers contemplate making C. D. Warren, president of the Traders' Bank and of the Metropolitan Traction Company, both of Toronto, president of the reorganized Consolidated Lake Superior Company. T. J. Drummond is slated for the vice-presidency. The New York banks have already consented to the change in the personnel of the Canadian Improvement Company, and it is stated that all of the Philadelphia banks have promised to sign.

MISSOURI & KANSAS TELEPHONE COMPANY.—The Missouri & Kansas Telephone Company (an American Bell licensee), reports as follows for the year ended December 31, 1903:

	1903.	1902.	1901.	1900.
Gross	$1,303,795	$1,228,436	$1,056,638	$863,235
Expenses	1,039,717	956,993	814,790	665,132

SAFETY CAR HEATING & LIGHTING.—The statement of the Safety Car Heating & Lighting Company for the year ending December 31, 1903, shows as follows: Net profits, $870,419, against $626,182 in 1902; paid out in dividends, $639,445, against $491,084; surplus, $230,974, against $135,098.

BELL TELEPHONE STOCKHOLDERS.—The number of stockholders of the American Telephone and Telegraph Company is now in excess of 16,500. Through the last increase in the company's outstanding stock, amounting to about $21,000,000, the number of stockholders was increased by about 3,000 names.

TROLLEY BONDS.—It is stated from Toledo that the Lake Erie, Bowling Green & Napoleon Electric Railway Company has issued and sold $1,000,000 5 per cent. thirty-year gold bonds, the money to be used to extend the present line to Fort Trenton and Napoleon.

Commercial Intelligence.

THE WEEK IN TRADE.—The conditions in trade throughout the country are much improved, due largely to the more favorable weather. Spring trade is "looking up" everywhere, and life is taking the place of the inactivity and dullness that prevailed generally through the effect of the prolonged cold weather. In the iron trade there is increased activity, and the prices of crude material are stiffer. The transportation situation is much improved, and the railway gross earnings for February promise to make a better showing than was anticipated. From many cities come complaints of collections notwithstanding the easy market and low prices for money. Reports from the South indicate an enormous acreage in cotton, and the reports of trade in most all lines are full of encouragement. Figures of iron production and stocks show that notwithstanding a large increase in the output, supplies on hand are smaller than during the winter. Finished products are also more active, and increased business is reported. From all parts of the country come details of much activity in agricultural implements. The copper market was inactive and extremely dull and transactions were very few. The prices quoted on the Mutual Exchange are 12½ to 12¾c. for Lake, 12⅜ to 12⅝ for electrolytic and casting stock. The London market was of the same character as that in New York. The business failures for the week ending March 10, as reported by Bradstreet's, numbered 200, an increase of five over the week previous, while those in the corresponding week last year numbered 176.

POWER TRANSMISSION IN IDAHO.—The Moscow Electric Light & Power Company, Moscow, Idaho, have made arrangements with the Lewiston Water Power Company to furnish them with 1,000 hp for distribution in the territory north of the Clearwater River. This power will be generated by a large water-power plant to be installed at the mouth of the Grand Ronde River and will be taken to Moscow, Genesee and other towns at a pressure of over 20,000 volts on a three-phase circuit. The current will be furnished twenty-four hours in the day. It is expected that power can be delivered in Moscow and Genesee by July 1, as construction work will begin by April 1 on the lines from Lewiston, and power will be supplied from the present plant of the Lewiston Company at Asotin until the large plant at the Grand Ronde can be installed. Engineers and surveyors have been at work on the plans since last fall and a plant will be installed that will cost nearly $1,000,000. Twenty-five thousand hp can be developed at the proposed plant, so there will be plenty of power to supply all that will be needed for some time to come. It is reported that a contract has been made with the large Word Flouring Mills at Genesee for power to run their mills and elevator twenty-four hours per day and also with the city for lighting the streets and pumping the water for the new waterworks plant to be installed this summer. Mr. M. J. Shields, president, and Mr. E. S. Aldrich, manager of the Moscow Electric Light & Power Company, state that they have been negotiating with Mr. Libby, of the Lewiston Company, for nearly a year, and have every assurance that the current can be delivered in Moscow by not later than August 1 of the present year. They also state that they will be able to save the city of Moscow at least 25 per cent. in pumping the city water, which will amount to a large sum when the new sewer system is put into operation as it will require at least double the water to be pumped that is being pumped now. The present steam plant will, of course, be held as a reserve power, but it is not expected that it will ever be needed as current has been on the lines of the present plant ten miles from Lewiston all the time for eighteen months and only one interruption of ten minutes has occurred.

ALLIS-CHALMERS DATA.—A great deal of interest is naturally being taken in the electrical field, in the advent of the Allis-Chalmers Company into it, not only as builders of reciprocating engines and other heavy mine and mill machinery, but of steam turbines, hydraulic turbines, gas engines and electrical apparatus. The acquisition of the Bullock Electric Manufacturing Company has also again attracted attention, as putting the company in line for immediate work of all kinds, including street railway motors. The capital stock issue of the Allis-Chalmers Company is $36,250,000 and of the Bullock Company $3,600,000, making a combined capital of $39,850,000. The total number of employees of the combined companies amounts to over 8,700 men. At the present time Allis-Chalmers are constructing for the Manhattan Elevated Railway system of New York about 100,000 hp in reciprocating engines having a capacity of from 3,000 hp normal to 12,000 hp maximum output. A duplicate of this important station is also being constructed for the Subway, New York.

ELECTRICAL EXPORTS.—The United States Department of Commerce and Labor has issued the figures in detail of January export trade. The total export of electrical machinery for the month was $455,091, as compared with $556,315 last year, while the total for the seven months was $2,892,251, as compared with $3,668,432 last year. The smaller demand was chiefly in England, where the amount was $875,431, or hardly one-half what was taken in 1903. The exports of electrical instruments of all kinds were $375,044 for the month, as compared with $239,234 in 1903. For the seven months the total was $3,177,106, as compared with $2,496,368 last year. The two items added together show $6,069,357, as compared with $6,164,800, so that on the whole the electrical export trade has been fully maintained despite the growth of American factories abroad.

THE INTERNATIONAL TELEPHONE MANUFACTURING COMPANY, Chicago, has recently greatly increased its manufacturing output in order to meet the heavy demands for the new telephone apparatus it is putting on the market. It has equipped its factory with considerable new machinery, including a number of large drill presses and full automatic Brown & Sharpe screw machines. The International Company has a full complement of special tools for manufacturing every distinct part of multiple switchboard central energy systems and generator-call exchange systems, including its improved self-restoring drop switchboard. Several recent heavy contracts are reported.

ILLINOIS TELEPHONE TUNNEL.—It is stated that President A. G. Wheeler of the Illinois Tunnel Company, which recently took over the assets of the Illinois Telegraph & Telephone Company, announces that bids for about 2,000 steel freight cars, to be operated in the tunnels underneath the downtown streets of Chicago, will be asked about March 15. Tentative operations are now being carried on in the tunnels where about twenty cars are already in service. Many of the large buildings and wholesale houses lying along the route of the tunnels are having connections cut into their basements. They will be ready to receive and deliver goods and supplies to and from railroad terminals and freight depots by July. President Wheeler also announces that since the preliminary work of the big tunnel company has been completed, the telephone plan will be pushed more vigorously. The company now has in the neighborhood of 5,600 automatic telephones in operation in the business district. Practically all business blocks have been wired for the new service and Mr. Wheeler expects that the present number of subscribers will have been doubled by July 1.

BELL TELEPHONE.—Boston advices say: "President Fish, of the American Telephone and Telegraph Company, during his recent Western trip, found the general business conditions of the Far West to be extremely satisfactory. There is no sign there of the distrust that is such a disturbing element in the East. The conditions of the Middle West are also favorable and the people confident. In Mr. Fish's opinion, the optimistic views of the West, which are justified by the situation there, will have a great influence in bringing about the restoration of normal financial conditions at a much earlier date than would be the case if the West shared to a greater extent the present somewhat unreasonable feeling of depression that seems to characterize the East. Mr. Fish reports the telephone situation as everywhere encouraging. About a quarter of a million new subscribers were added to the Bell system during the year 1903, and the growth still continues. The development on the Pacific coast is extremely satisfactory, the number of telephone subscribers there being enormously greater in proportion to the population than in any other part of the country."

SOME BUFFALO FORGE COMPANY ORDERS.—The Buffalo Forge Company, 39-41 Cortlandt Street, has secured a contract from the American Coke and Gas Company, of Pittsburg, for a small lighting equipment for one of its Ohio plants. The Buffalo vertical engine will be direct connected to a Westinghouse generator. Blackall & Baldwin, Taylor Building, New York City, have also placed an order for a small lighting set for use in William Crafts & Company's plant at Newark, N. J. The generator will be of Crocker-Wheeler manufacture. A small ventilating outfit has been ordered for the Hotel York, Thirty-sixth Street and Sixth Avenue. The motors will be of General Electric build.

EQUIPMENT FOR NEW GORHAM PREMISES.—The Gorham Manufacturing Company's new premises, at Thirty-sixth Street and Fifth Avenue, New York, are to be installed with several electrically operated pumps, fans, etc., in connection with the heating and ventilating system. There will be two 1½-in. Buffalo centrifugal pumps and two 5-in. x 8-in. triplex pumps of same build, direct connected to Crocker-Wheeler motors. The steel plate fans will be five in number, varying from 7½ ft. to 4 ft. The Buffalo Forge Company also secured the contract for these outfits, which will be driven by Crocker-Wheeler motors.

G. M. GEST, the expert subway contractor, of New York and Cincinnati, has been awarded the contract for the construction of a heavy 40-duct conduit system by the Public Service Corporation of New Jersey. This system will run into thousands of dollars in cost and is a main trunk feeder line running through Hoboken and Jersey City. Work is to be begun on the 15th of March and a large force of men is to be employed to push the work rapidly. Mr. Gest has also closed with the B. M. & J. F. Shanley Co., of Jersey City, a contract for laying its conduits in Harrison, N. J., and Kearney, N. J.

THE ELECTRIC STORAGE BATTERY COMPANY, of Philadelphia, has recently closed a contract with the Northern Illinois Lighting & Traction Company at Ottawa, Ill., for the installation of a battery of "Chloride" accumulators having a capacity of 160 kw-hours. This battery is to be used for current regulation. Contracts have also been closed for residential lighting and power plants for H. B. King, Prides Crossing, Mass., and Dr. C. E. Parker, Princeton, Mass., and with Frederick L. Milliken at Milton, Mass., for an isolated lighting plant.

THE NATIONAL ELECTRIC COMPANY, Milwaukee, Wis., successor to the Christensen Engineering Company, manufacturer of air brake and electrical machinery, has just moved its executive offices and engineering department to its new building located at the works. The building is constructed of cement blocks 2 ft. long by 1 ft. high and is 200 ft. long x 66½ ft. wide. Extensions and improvements are also being made in the company's shops to supply the necessary facilities for handling its constantly increasing business.

LIGHTING EQUIPMENT FOR MEXICAN SUGAR PLANT.—The Reeves Engine Company, of Trenton, N. J., New York offices, Singer Building, has taken an order for a vertical cross compound engine for direct connection to a Crocker-Wheeler generator to be installed for the purpose of lighting the Panuco Sugar Company's plant at Tampico, State of Vera Cruz, Mexico. A 400-hp Reeves vertical cross compound engine, for direct connection to a centrifugal pump, has been ordered for a large rice plant near Houston, Tex.

WESTINGHOUSE EQUIPMENT FOR BRITISH STEEL WORKS.—The British Westinghouse Electric & Manufacturing Company, Limited, has been awarded the contract for the electrification of the extensive steel works operated by the Carnforth Iron & Steel Company, Limited. The Carnforth plant is being remodeled on American lines, Julian Kennedy, Sahlin & Co., Limited, London, of which Julian Kennedy, the well-known American metallurgical expert is one of the principals, having undertaken the work.

EQUIPMENT FOR NEW JERSEY NEWSPAPER PLANT.—The printing plant of the *Freie Zeitung*, at Newark, N. J., is to be electrically operated throughout. In the meantime, an order has been given for a lighting equipment. MacKenzie, Quarrier & Ferguson, 114 Liberty Street, acting on behalf of the Harrisburg, Pa., Foundry and Machine Works, secured the order for the engine, which will be direct connected to a Westinghouse generator.

PHILLIPS' CANADIAN FACTORY.—The Eugene F. Phillips Electrical Works, Limited, Montreal, Canada, intend adding to their factory plant the coming season one building 275 by 60 ft., one story high, and another building 180 by 60, three stories. The plant will be erected in the town of St. Louis. Nothing has been decided on yet as regards power. Mr. Geo. H. Olney, 2d, is the resident secretary and treasurer.

MEXICAN MINES.—The American-Mexico Mining and Development Company, which owns large mining interests in the vicinity of Torreon, Mexico, is to install a $50,000 electric plant at its Velardena Camp, for the purpose of lighting and operating the mines. Dr. W. S. Phillips, of Chicago, Ill., is president of the company. Dr. A. T. Grove, also of Chicago, is secretary-treasurer.

ALBERGER CONDENSERS FOR TESTING.—The Alberger Condenser Company, White Building, Liberty Street, New York, has secured a contract for two large high vacuum condensing equipments with two-stage vacuum pumps for installation in the turbine testing rooms of the Westinghouse Machine Company. They will be utilized to test turbines varying from 4,000 kw to 5,500 kw capacity.

AMERICAN TELEPHONE ORDERS.—Among switchboard shipments recently reported by the American Electric Telephone Company, of Chicago, are the following: Kenton, Ohio, one 100-line express; Adrian, Mich., one 100-line express; Three Lakes, Wis., one 25-line express; Muscatine, Iowa, two 100-line express; Frankford, S. Dak., one 100-line express.

INTERBOROUGH PACKAGE EXPRESS.—The question of operation of a package express on Interborough lines has been receiving consideration from Interborough interests. The question of a contract with the United Express Company has not, however, been brought formally before directors of the Interborough Rapid Transit Company.

PLANT FOR MEXICAN PLANTATION.—The Mexican Tropical Planters' Company, which possesses a large property known as the Columbia plantation, located on the Coatzaconlcos River, Isthmus of Tehuantepec, is about to be in the market for a large electric lighting plant. Mr. Louis Kunz is the general manager.

CONTRACT FOR MONCLOVA.—The contract has been let for the lighting and power plant for the city of Monclova, State of Coahnila, Mexico. Victor M. Braschi & Bro., of Mexico City, will undertake the work. The plant will entail an expenditure of about $100,000 gold.

PLANT FOR CUBAN SAW MILLS.—The Mackay Engineering Company, Singer Building, Broadway and Liberty Street, New York, has taken a contract for a complete electric plant to be used for lighting and operating large saw mills at Santiago de Cuba.

APPARATUS WANTED.—The Weston West Virginia Electric Light, Power & Water Company is in the market for a 300-hp steam turbine direct-connected to two 100-kw direct-current generators, 125 volts. Mr. J. S. Mitchell should be addressed on the subject.

CHICAGO TELEPHONE COMPANY shows for February a gain of 1,724 Bell instruments, making the total of subscribers in the system 104,368.

THE WATERBURY BATTERY COMPANY, of Waterbury, Conn., have increased their capital stock from $10,000 to $50,000.

General News.

THE TELEPHONE.

HANFORD, CAL.—The Independent Telephone Company has been incorporated with a capital stock of $25,000 to build a line from Lemoore to Hanford, a distance of ten miles. The incorporators are: H. L. McCubbin, P. Carrasco, and J. Mills.

WASHINGTON, D. C.—In the District appropriation bill which is now before the House, there is a paragraph relating to telephone service in the District. An amendment thereto has been offered by Mr. Bartlett, providing that none of the money appropriated shall be paid except at the following rates: $50 per annum for the use of a telephone on a single wire; $40 for each telephone where there are two in a wire; $30 where there are three; and $25 each where there are four or more on the same wire.

SEYMOUR, IND.—The Seymour Home Telephone Company is installing a 500-line board of the new lamp signal type manufactured by the Sterling Electric Company, of Lafayette, Ind.

SELMA, IND.—The Selma Co-operative Telephone Company has decided to purchase property for a new exchange. It will install a new switchboard and otherwise improve its plant and service.

MONROE CITY, IND.—The Wabash Home Telephone Company, operating an exchange and system in this city, has increased its capital stock $25,000. The corporation will make extensive improvements in the exchange and extend its lines during the present year.

ETHEL, IND.—The Morning Star Telephone Company has incorporated for the purpose of installing an exchange and telephone system in this city, Crawford and adjoining counties. The capital stock is $5000. The incorporators are: Joseph R. Allen, of Ethel; W. H. Williams and William J. Truly, of Traswell.

WARREN, IND.—The Warren Telephone Company's plant has been sold to George Griffith and Frank Canaday, who will organize a new company. The plant has been in operation for five years and includes a number of country lines. The new management will take charge April 1, when a general system of improvement will be begun.

SALAMONIA, IND.—The Salamonia Telephone Company has filed articles of incorporation with the Secretary of State. The company proposes to install an exchange and erect and operate telephone lines in this city and throughout Jay County. The capital stock is $5200. H. E. Barting, J. J. Kidder, John W. Crull and others are the incorporators.

NEW PALESTINE, IND.—The New Palestine Telephone Company, which operates a telephone system in the southern part of Hancock County, has planned to extend its lines into the northern part of Shelby County. A new metallic circuit will be put in, also a new switchboard in the exchange. The company has increased its charges from $1.20 to $2.

TERRE HAUTE, IND.—An important meeting was held in this city on March 2 by the representatives of independent telephone exchanges in eastern Illinois and western Indiana, representing a total of 14,000 telephones. The purpose of the meeting was to arrange a uniform long distance rate. Plans were made and a secretary employed to give his entire time to the unifying of distance and applying the schedule of rates thereto.

SCHLESWIG, IA.—The Schleswig Telephone Company will build 30 miles of new line.

CAMBRIDGE, IA.—The Cambridge Independent Telephone Company will extend its system during the coming season.

VAN WERT, IA.—The Van Wert Rural Telephone Company has elected officers as follows: President, F. L. Hall; vice-president, J. F. Hockler; secretary, H. O. Tuttle; treasurer, F. O. Stearns.

LAKE CHARLES, LA.—Application has been made to the City Council by W. C. Easterling and W. C. Pfeiffer, representing Pennsylvania capitalists, for a franchise for installing a telephone system here.

GRAND HAVEN, MICH.—The Michigan Telephone Company is extending its lines from this city into the townships of Grand Haven, Robinson and Olive, and will expend several thousand dollars in extension work.

DETROIT, MICH.—The receiver of the Michigan Telephone Company will, about March 15, turn over the property of the concern to President W. A. Jackson, of the Michigan State Telephone Company, its successor.

NEW YORK MILLS, MINN.—A telephone company is being organized in this place.

GRANITE FALLS, MINN.—A farmers' telephone company has been organized at Stony Run.

TORDENSKJOLD, MINN.—A farmers' telephone company is projected here. Mr. E. E. Olson is interested.

VERNON, MINN.—The Farmers' Interurban Telephone Company has been incorporated with a capital stock of $50,000. The directors are B. C. Roe, A. S. Berge and others.

MONTROSE, MINN.—The Montrose Farmers' Telephone Company, of Montrose, Wright County, has been incorporated with a capital stock of $10,000, the incorporators being: C. A. Stolyman, A. C. Strey, E. W. Swanson, F. E. Belden, C. P. Stapleton, J. P. Thornquist, Louis F. Miller, F. G. Miller and C. F. Denvon, Montrose.

HARRISONVILLE, MO.—The Cass County Telephone Company has been incorporated with a capital stock of $50,000. The directors are R. W. and D. Adams.

ST. LOUIS, MO.—The Bell Telephone Company announces that beginning March 1, in the unlimited residence service, the direct line which has been $72 a year was reduced to $60, and the duplex line (two telephones on one line) was reduced from $48 to $42 a year. The charges for these services were at one time $80 and $60 a year. No other rates are changed. The Kinloch Telephone Company has recently made a $36 rate for its unlimited service, two-party residence telephones. Its one-party line, unlimited service rate remains $48. The Kinloch Company is rapidly extending its long-distance service and expects to connect with the system of the United States Telephone Company in Ohio before the opening of the World's Fair. Its lines are now within seventeen miles of the Ohio State line. When they reach Ohio and join those of the United States Telephone Company, they will be connected with 80,000 telephones east of Indiana. The company then will be able to reach Philadelphia and Buffalo and nearly all principal points in the interior of New York and Pennsylvania. In less than one month the lines will be connected with one of the telephone companies in Kansas City, and through its wires, with all important points in Kansas. These wires also reach St. Joseph and North Missouri. The line to Joplin is nearing completion. This line will give connections in Oklahoma, Indian Territory and Texas.

BARTLEY, NEB.—A new telephone company has been formed here.

KENESAW, NEB.—Mr. S. A. Westing is interested in a proposed telephone exchange in this place, which is to be organized with a capital stock of $10,000.

ALBANY, N. Y.—The Conesville & Gilboa Telephone Company, of New York, has been incorporated with a capital stock of $1000. The incorporators are: J. W. Gaylord, B. C. Wright and Elmer Baker.

TREADWELL, N. Y.—The Treadwell Telephone Company has been incorporated with a capital stock of $3000. The incorporators are: Robert Ballantine, Duane D. Wheat, of Treadwell, and U. R. Ogden, of Leonta.

NEW YORK, N. Y.—The New York Telephone Company will install a new exchange at 22 Cortlandt Street, to be called "Liberty." The new exchange will relieve the Cortlandt exchange of several hundred subscribers. Other down-town exchanges will also be relieved in a similar manner.

UTICA, N. Y.—At the recent annual meeting of the boards of directors of the Central New York Telephone & Telegraph Company and the Empire State Telephone Company, officers were elected as follows: For the Central New York Company—President, U. N. Bethell, New York City; vice-president; Joseph Rudd, Jr., Utica; secretary and treasurer, Francis G. Wood, Utica; chairman of the board of trustees, Charles F. Cutler, New York City. For the Empire State Company—President, U. N. Bethell; secretary and treasurer, Francis G. Wood; chairman of the board, Charles F. Cutler. No vice-president was elected.

COLUMBUS, N. C.—The Columbus Telephone Company is completing the installation of metallic circuits, thus affording long distance connections through the Bell Company with many outside points.

CHAGRIN FALLS, OHIO.—The exchange of the Chagrin Falls Telephone Company was destroyed by fire recently.

ADAMSVILLE, OHIO.—The Adamsville Telephone Company has been incorporated with a capital stock of $1000.

BRITTAIN, OHIO.—The Springfield Township Rural Telephone Company has been organized with a capital stock of $10,000. The incorporation papers are to be applied for at once.

COLUMBUS, OHIO.—The Waldo Home Telephone Company, of Waldo, has been incorporated with a capital stock of $25,000. The company will build systems in Marion, Union, Delaware and Morrow counties. The incorporators are: William Klingel, M. Lewis, A. Oborn, W. D. Kraemer and Sam Schwaderer.

TIFFIN, OHIO.—The Home Telephone Company, which recently increased its capital stock from $60,000 to $125,000, has changed its name to Tiffin Home Telephone Company. New officers have been elected as follows: President, F. B. Myers; vice-president, K. F. Briggs; treasurer, James J. Kintz; secretary and superintendent, Edwin R. Strohm.

SHIPPENSBURG, PA.—The subscribers of the United Telephone Company in this city are objecting to the discontinuance of free service to Carlisle and Wainsboro after April 1. The company proposes to charge tolls for conversations between the points named.

PORT BOLIVAR, TEX.—Messrs. Tuggle and Kitchen, of this place, are constructing a telephone line from here to High Island.

BELTON, TEX.—The Moody Telephone Company, of this place, has been granted a franchise to extend its lines through portions of the country.

SAN MARCOS, TEX.—The franchise of the Southwestern Telegraph & Telephone Company in this place has been declared forfeited by the City Council.

EL PASO, TEX.—Sam Byrne and S. Nicholls, of De Soto, Mo., are investigating the independent telephone situation here with the view of acquiring the uncompleted plant of the local system, which was started by Mrs. Brett. If the consent of the city authorities can be obtained, the system will probably be rehabilitated and completed.

CHRISTIANA, WIS.—The Christiana Farmers' Telephone Company has been incorporated, the directors being P. O. Nelson, S. Haight and others.

SILVER CITY, N. MEX.—It is announced that the Grant County Telephone Company, of this place, will build a long distance telephone line to the different mining camps situated in the Burro Mountains. This company now has an extensive telephone system, extending to all the leading mining camps and towns in the southwestern part of New Mexico.

TORONTO, ONT.—The Stark Telephone, Light & Power Company has applied to the city of Toronto for the privileges of establishing a telephone, light and power service within the city limits, and to obtain the right to lay down conduits, wires and cables, and where necessary to erect poles and string wires. The company promises to give a telephone service at $6 per year, and one cent per outgoing call for telephones in private houses, with a limit of $15 per annum. The rate for business telephones is to be $6 per annum and one cent per call, with a limit of $35 per annum. The company also promises reduced rates for light and power. It has already secured over 4000 telephone subscribers, and will proceed at once to install its system.

Electric Light and Power.

SAN DIEGO, CAL.—The City Council has granted Charles E. Sumner, of Cleveland, O., an electric light and gas franchise. Mr. Sumner is supposed to be backed by H. E. Huntington, of Los Angeles.

RIVERSIDE, CAL.—The City Trustees are considering a proposition to establish a municipal electric light plant. The Tracy Engineering Company, San Francisco, has submitted a definite proposition to the trustees.

EUREKA, CAL.—The Eureka Lighting Company, it is stated, will at once begin the development of its water power on Trinity River, for the purpose of generating electric power. The plans contemplate the expenditure of nearly $500,000.

WHEATLAND, CAL.—The power line which the Bay Counties Power Company is building from the power house at Nimshew is nearly completed and will reach Colgate in the near future. The necessary equipment for the proposed extension has already arrived.

SAN FRANCISCO, CAL.—An additional generating equipment of 400-kw., in two units, will be installed in the isolated electric plant in the basement of the Rialto Building. The 500-hp boiler plant will be supplied through the California Engineering and Construction Company, the contract calling for three Franklin boilers of the Heine water-tube type. A new seven-story hotel to be erected on Market Street, adjoining the Palace, will be supplied with electric light and power from this plant, as well as the Rialto Building annex.

SAN FRANCISCO, CAL.—The Big Creek Power Company, of Santa Cruz, Cal., C. E. Lilly manager, has closed a contract for an additional Westinghouse alternating-current generator of moderate capacity. The Power Company contemplates the erection of an additional generating station at Chittenden from which it can supply light and power to Watsonville, Gilroy and Hollister. If satisfactory terms can be obtained for fuel, a large steam plant will be installed and fuel oil will be piped in from the Watsonville Oil Company's wells. The present plant is operated by water power and is inadequate to supply the demand.

SAN FRANCISCO, CAL.—The Watsonville Light & Power Company, which has been incorporated by C. W. Waller, A. W. Linforth, F. M. Ray, J. C. Love and J. H. Foote, with a capital stock of $250,000, is controlled by John Martin and other representatives of the California Gas & Electric Corporation. The latter company, which owns numerous lighting plants in Northern California, has only one as far south as Fresno, but the new acquisition may result in extending the system southward along the coast. The Watsonville Light & Power Company will absorb in Watsonville two gas companies and the Watsonville Electric Light Company's steam plant, installed by F. M. Smith.

COLORADO SPRINGS, COL.—The Colorado Electric Power Company is made the defendant in a foreclosure suit brought by the Union Trust Company, of Pittsburg, as trustee. The suit is to recover $2000 and interest, which with other claims brings the total up to $226,700.

WASHINGTON, D. C.—Bids will be received March 22 at the Bureau of Supplies and Accounts, Navy Department, Washington, for furnishing at the Navy Yards, Portsmouth, N. H., and Boston, Mass., a quantity of steel-plate fans, blowers, electric motors, arc lamps, rubber and lead-covered wire and cable, conduit and fittings, electrical supplies, iron pipe, pipe fittings, valves, etc.; also April 5 at the Navy Yards, Mare Island, Cal., and Puget Sound, Wash., a quantity of electric blowers, motor generator set, conduit and fittings, electrical supplies, iron wire, galvanized sheet steel, wrought iron pipe, rivets and asbestos cement, Portland cement, etc. H. T. B. Harris, Paymaster-General, U. S. N.

COVINGTON, GA.—C. C. Brooks, of Covington, writes that it is proposed to develop the water power of Alcova River at a cost of $100,000. The company is not yet organized.

BLUE RIDGE, GA.—E. B. Garwood, manager Blue Ridge Electric Light & Power Company, writes that it is proposed to construct a larger plant for lighting and power, to be operated by water.

BELLEVILLE, ILL.—A mortgage for $350,000, to cover an issue of bonds to that amount, was filed in the St. Clair County Recorder's office in this city, March 1, by the East St. Louis Trust & Savings Bank, trustees for the Muskogee Electric & Gas Company of Indian Territory. The East St. Louis Trust & Savings Bank probably will float the bonds.

ALTON, ILL.—A movement is on foot in North and Upper Alton to secure a joint lighting plant of their own, and thus be independent of the Alton Light & Traction Company, which is now furnishing current to both towns at what is considered an exorbitant price. The idea is to locate the power house midway between the two towns, which are only a few miles apart, and to secure a plant sufficiently large to fill the needs of both places. The town of Grafton has just made a lighting contract for ten years whereby the village secures an all-night service every night in the year for about $30 per light.

MONTICELLO, IND.—The Tippecanoe Power Company has purchased from Bradner & Smith what is known as the Tioga Paper Mill site at Tippecanoe Falls, near Monticello, Ind. The 100 acres adjacent to the falls is being cleared of timber to make locations for factories. The plan of the company is to develop 5000 horse-power from the falls. Two dams will be built. Theophilus King, banker, Boston, Mass., is at the head of the company.

LONDON, KY.—The London Electric Light Company has been chartered, with R. M. Jackson president.

BALTIMORE, MD.—A bill has been introduced in the House at Annapolis providing for the municipal ownership of an electric lighting plant in this city. The question whether the plant shall be established, and the debt therefor contracted, will be submitted to the voters at the general election in 1905.

BROWNING, MO.—Carl Thudium, of Brookfield, is interested in the construction of an electric light plant.

ST. JAMES, MO.—Chas. W. Orendorf and J. W. Scott, of St. Louis, have secured a franchise from the City Council for an electric light plant, also right of way through the town and depot facilities for an electric road to be constructed from Jefferson City to a point on the Mississippi River opposite Chester, Ill.

COLUMBIA, MO.—The citizens have voted to issue $100,000 bonds for the purchase by the city of the water works and electric light plants owned by the Columbia Water & Light Company. The plant will be purchased for $67,000, will be improved and a system of deep wells installed.

ST. LOUIS, MO.—A municipal plant for lighting that portion of the city south of Keokuk Street is being planned by the city officials. The introduction of an ordinance providing for the plant hinges upon the amount of money demanded by the police board. Should the amount required for the police not be excessive, it is thought that the city can afford the $140,000 which will be needed to erect an electric lighting plant. The location of the plant has already been selected. It is intended to place it on the river front, between Elwood and Kraus streets. The territory whch it is intended to light is now divided between the Carondolet Gas Company and the Welsbach Lighting Company. The first company receives $54,000 annually and the latter $5000.

WEBSTER, N. H.—Horace J. Davis, of Contoocook, general manager of the Blackwater Power Company, writes that it is proposed to develop the power of Blackwater River at Webster.

WEEHAWKEN, N. J.—The Committee on Lighting has been directed to have plans prepared for an electric light plant for the township, to be installed in the new pumping station at a cost of about $5000.

NIAGARA FALLS, N. Y.—It is stated that the Toronto & Niagara Falls Power Company has decided to use steel towers for its transmission line between Niagara Falls, Ont., and Toronto. The towers will be 8 or 10 feet square at the base and about 50 feet high, and will be placed at intervals of 400 feet.

NEWBURGH, N. Y.—Mr. T. E. Hayes, of Middletown, has been appointed receiver for the Neversink Light & Power Company, which has a plant at Rose's Point, near Cuddebackville. The appointment of a receiver is the result of the action brought by Mr. Hayes to recover on a promissory note upon which judgment was taken and sequestration proceedings instituted. The Neversink Light & Power Company began business about a year ago and has furnished power to Port Jervis for street lighting, also for the electric railway operated by the Port Jervis Gas, Electric Light & Power Company.

FAYETTEVILLE, N. C.—The Cape Fear Electric Power Company is laying the foundations for a sub-station in Fayetteville for the transmission of power from the river to the town, to be utilized in mills and other industries.

ASHEVILLE, N. C.—The Biltmore estate, near Asheville, has been furnished power for the first time over the transmission lines of the W. T. Weaver Power Company's plant. The power, however, does not come from this company's plant, which will not be ready to furnish the same until April 1, when the Biltmore estate will take 250 horse-power and the Asheville Electric Company will take 600 horse-power.

GLACE BAY, N. S.—Glace Bay about two years ago installed an electric light system which is owned and operated by the town. The people have been given a good electric service, cheap light, and on the operation last year the town cleared the sum of $1,800 over and above operating expenses.

BRIDGEWATER, N. S.—The town of Bridgewater earned last year, through its electric light plant, which is municipally owned and operated, over $1,700 above expenses, and the saving thus enabled the town to have its streets lighted, water for fire protection and good sewerage without cost to the town.

CLEVELAND, OHIO.—The contract of the city with the Cleveland Electric Illuminating Company fixes a price of $75 per arc per year.

BELLEFONTAINE, OHIO.—The Board of Public Service has received plans for the municipal electric light plant, which, it is estimated, will cost $10,000.

YORK, PA.—The floods during the first week of the month caused damage to the power plant at York Haven to the extent of about $5000.

CHAMBERSBURG, PA.—The Shippensburg Electric Light, Heat & Power Company has been amalgamated with the Shippensburg Gas & Electric Compand. The new combination has a capital of $45,000.

YORK, PA.—The directors of the recently chartered Deer Creek Water & Power Company have effected an organization by the election of the following named officers: President, James H. Gable, of York; vice-president, J. Benson Gable; secretary, J. N. Wilson; treasurer, Charles F. Ramsey; superintendent of construction, J. K. Green, of York. The company proposes to construct a dam and power plant on Deer Creek, one mile from Stewartstown, for the purpose of furnishing water power and electric light to Stewartstown and vicinity.

SHERBROOKE, QUE.—The City Council has accepted the offer of the Heat, Light & Power Company for its plant, for $233,000, but before the contract is made with the company the question will be submitted to the property holders for their approval.

CARTHAGE, TENN.—Dr. Drake is interested in the construction of an electric light plant.

FARMERSVILLE, TEX.—The Farmersville Mill & Light Company has been organized, with a capital of $50,000. H. L. Carver and E. W. Stewart are interested.

TOOELE, UTAH.—The Clark Electric Company, of Tooele, is considering the installation of an electric light plant near Richfield.

EMPORIA, VA.—The Greenesville Water Power Company has been incorporated at Emporia, Va., with a capital of $10,000 to $50,000. W. Samuel Goodwyn is president of the concern.

BELLINGHAM, WASH.—The Likens-Wyatt Power Company has been granted a franchise to establish and operate a power plant in this city.

WAUPACA, WIS.—The Waupaca Electric Light & Power Company has increased its capital stock from $75,000 to $125,000.

OMRO, WIS.—The Omro Electric Light Company has been incorporated with a capital of $10,000.

THE ELECTRIC RAILWAY.

BIRMINGHAM, ALA.—The directors of the Birmingham Railway, Light & Power Company have issued a call for a meeting of the stock-holders, to consider the proposition of negotiating a loan of $1,000,000 for improving the system. The company proposes to double the capacity of the electric power plant and the gas plant, and to make extensions and improvements on its street railway system.

STONINGTON, CONN.—The contract for the building of the Groton & Stonington Street Railway has been awarded to the John B. Macafee Company, of Philadelphia. The contract includes the power station complete.

HARTFORD, CONN.—The Hartford Street Railway Company has applied to the municipal authorities for approval of its plans to extend its lines within the city limits. The company has also under contemplation the extension of its suburban lines.

BRIDGEPORT, CONN.—The Connecticut Railway & Lighting Company is enlarging its power station for the Bridgeport division of its system. The plant has been extended and an 800-kw generator, directly connected with a 1200-hp engine, is now being installed. It will be at least two months before the new generator will be ready for use. The plant will then have a capacity of 3600 horse-power, and will supply power, not only for the local lines, but for the Milford and Westport branches.

MATTOON, ILL.—The promoters of the Mattoon-Charleston Electric Railway will in all probability construct a line between this city and Champaign, as a continuatinn of the former line.

ROCK ISLAND, ILL.—The Tri-City Railway Company is perfecting plans for concentrating all its power generating plant into one large station on the site of the present plant in First Avenue, Rock Island, from which it will be able to furnish current for the operation of all its lines in the three cities. At the present time the Rock Island plant only furnishes sufficient power for the operation of the cars on the Illinois side of the river, and it has been found necessary to obtain power from the People's Power Company for the operation of the lines in Davenport. The improvements will involve a large investment of capital.

WARSAW, IND.—The City Council has granted a franchise to the Goshen, Warsaw & Winona Electric Railway. Cleveland capitalists, headed by J. B. Hanna, are behind the project, and there is no doubt about the immediate building of the road.

WABASH, IND.—The contract for all the material to be used in the completion of the Wabash & Rochester Electric Railway has been awarded to a New York firm. The contract includes rails and overhead work, power house machinery and cars. The work of grading for the road began March 1.

FT. WAYNE, IND.—The Ft. Wayne, Logansport, Lafayette & Lima Traction Company has filed amended articles of association with the Secretary of State, changing its name to the Ft. Wayne & Wabash Valley Traction Company. The articles also provide for the extension of the system to Goshen, Elkhart, Mishawaka, South Bend, Ligonier and other places. The directors of the newly-formed company are: H. C. Paul, J. L. Jones, Randall Morgan, Bayard Henry, S. B. Fleming, James Murdock and G. F. McCulloch.

DUBUQUE, IA.—At the recent annual meeting of the stockholders of the Union Electric Company, held in this city, a plan of procedure was mapped out for the improvements which are to be made to the property. All the tracks, both inside and outside the city limits, will be relaid and the roadbed placed in first-class condition, and a new power house will be built and improvements made in Nutwood Park. The new power house will be of such capacity and facilities that ample power will be furnished for the operation of the street railway system and the electric light plant, and the entire system will be as modern as it is possible to make it.

WORCESTER, MASS.—Claims against the Worcester & Southbridge Street Railway Company were filed recently with Charles M. Thayer, one of the receivers. A greater portion of the claims will be settled on a 50 per cent. basis through a syndicate, which plans to operate the road. Several persons, however, have refused to settle on that basis.

MIDDLEBORO, MASS.—John T. Burnett, of Southboro, and John L. Hall, of Boston, have been appointed receivers of the Middleboro, Wareham & Buzzard's Bay Street Railway Company. The appointment was the result of a suit brought by the American Electrical Works, one of the company's creditors. The receivers have been authorized to operate the road.

OWOSSO, MICH.—The Owosso & Corunna Traction Company has sold its line to a Pennsylvania syndicate that controls a number of lines around Allentown, Pa., and also has control of the public lighting franchise in the city of Flint. The new company has secured an extension of franchise rights in Owosso and Corunna, and will also extend the road to Durand.

BENTON HARBOR, MICH.—The Kalamazoo & Lake Michigan Railroad Company will have 66 miles of interurban road, from Kalamazoo to Benton Harbor, Mich., constructed this year by the Western Engineering & Construction Company, Chicago. G. A. Mullins is general manager, and Eric Wolff is chief engineer and general superintendent. Contracts are now being let. The road will have five sub-stations. Two direct-connected 1000-kw units will be installed in the power house.

KANSAS CITY, MO.—The Fifteenth Street line of the Metropolitan Street Railway Company is to be extended to Centropolis.

RENO, NEV.—It is officially stated that the new electric railway between Reno and East Reno is an assured fact, and that work is to begin immediately. J. B. O'Sullivan, president, states that the material for constructing the line has been shipped.

RALEIGH, N. C.—The Raleigh Electric Street Railway is considering a proposition to build a 28-mile line to Durham.

JAMAICA, N. Y.—The New York & Long Island Traction Company has filed in the Queens County Clerk's office its franchise granted by the Board of Aldermen, permitting it to lay about 25 miles of track in the town of Jamaica over three routes extending in an easterly and westerly direction.

NEW YORK, N. Y.—William G. McAdoo, president of the New York & New Jersey Railroad Company, which is building the tunnel recently completed, from Jersey City to New York, has sent to the Rapid Transit Commission an application for permission to extend the New York spur of that tunnel up to Sixth Avenue and Thirty-third Street. According to the plan he proposes, the tunnel will continue from West Tenth and Greenwich Streets, where its terminal originally was projected, in a northeasterly direction under West Tenth Street to Sixth Avenue, and then straight up the avenue to Herald Square.

NIAGARA FALLS, N. Y.—The International Railway Company's new power house in North Tonawanda has been completed and is now in operation. The power plant supplies energy for the Buffalo & Niagara Falls line from La Salle to the Buffalo city line; the Buffalo & Lockport Railway from the Buffalo city line to Lockport, and the Buffalo & Kenmore line from the Buffalo city line to Gratwick. The equipment is of the General Electric Company, and consists of three 350-kw rotaries. There is also a 1200-ampere-hour battery which was installed by the Electric Storage Battery Company. The International Company's new power house in Lockport is also in operation. This plant takes care of the Lockport-Olcott line; the local street railway and the Gulf branch. It also supplies power for the Buffalo-Lockport line from Lockport to North Tonawanda. In this plant are installed two 350-kw rotaries and an 1800-ampere-hour battery.

NEW YORK, N. Y.—Borough President Littleton, of Brooklyn, made public his plans for the proposed municipal elevated railroad to connect the terminals of the Brooklyn and Williamsburg bridges on both sides of the river. The suggested road is to be built, owned, and operated by the city. Mr. Littleton's plan provides for the construction of an elevated road through Centre and Delancey Streets, in Manhattan, connecting the termini of the two bridges, with stations at the terminal of the Brooklyn Bridge, Centre and Worth Streets, Centre and Howard Streets, Delancey Street and the Bowery, Delancey and Allen Streets, and the terminal of the Williamsburg Bridge. The proposed railway would cross the Williamsburg Bridge to South Fifth Street, Williamsburg, up this street to Union Avenue, and to Broadway to Throop Avenue to Willoughby Avenue, through Fort Greene Park by a tunnel under the hill to Willoughby Street, to Fulton, to Washington, to the Brooklyn terminal of the Brooklyn Bridge. The proposed road would be partly a four-track and partly a two-track structure, and there would be eight stations on the line in Brooklyn. Mr. Littleton and Commissioner of Public Works John C. Brackenridge estimate that the proposed railroad would cost about $10,000,000. They figure that with a three-cent fare it would pay 3½ per cent. on the bonds and leave a net profit of nearly a quarter of a million dollars each year.

MONESSEN, PA.—The Webster, Monessen, Belle Vernon & Fayette City Street Railway will extend its line to Fayette City.

HARRISBURG, PA.—A charter has been granted at the State Department to the Wayne Electric Street Railway Company, capital $6000, to build a one-mile line at Wayne.

CHAMBERSBURG, PA.—The Chambersburg & Gettysburg Electric Railway Company has secured an option on a property in this town which is to be used as a site for a power house.

ELWOOD CITY, PA.—A franchise has been granted to the Elwood City Electric Street Railway Company. This railway will connect with the Newcastle and Beaver Falls lines at Whitedale, three miles west of this place.

LANCASTER, PA.—A charter has been granted to the Strasburg & Georgetown Street Passenger Railway Company, capital $6000, to build a one-mile line from Strasburg turnpike along the Georgetown public road. This is to be part of the system to connect this city and Philadelphia. Albert H. Swing, of Coatesville, is president.

WEST CHESTER, PA.—It is reported that a plan is being considered for the merging of the interests of the West Chester Street Railway Company with those of Wilmington capitalists who have franchises in that city, and to the Delaware line, the combined company to construct and operate an electric railway between Wilmington and Lenape.

LANCASTER, PA.—A conference has been held between representatives of the Lancaster & Quarryville Trolley Company and the Conestoga Traction Company regarding a connection with the Strasburg line at Elliott's Corner. The new line will follow the Big Spring and Beaver Valley pike from Repton to Elliott's Mill. The route is now being surveyed.

MONTREAL, QUE.—Dr. Payette, of this place; J. E. E. Dickson, of Westmount, and H. Fontier, of Montreal, are applying for a charter to build an electric railways through the counties of Hochelaga, Jacques Cartier, Laval, Two Mountains, Argentine and Terrebonne.

PROVIDENCE, R. I.—An act to incorporate the Worcester & Providence Street Railway Company was introduced in the House of Representatives and referred to the Committee on Corporations. The act authorizes the issuing of $1,000,000 of capital stock and the issue of bonds for a like amount; also authorizes the company to acquire land by condemnation and to lease and buy other railroads.

OGDEN, UTAH.—The Ogden Rapid Transit Company has been granted a franchise to operate a street railway system through some of the most important streets of the city.

NORFOLK, VA.—Mr. R. I. Mason, receiver for the Hampton Roads Electric Railway, will, it is reported, apply for permission to issue $150,000 of receiver's certificates to complete the road.

WALLA WALLA, WASH.—James Galloway has asked the City Council for a franchise for an electric street railway, claiming that he represents eastern parties in the enterprise. The Council has previously been troubled with unreliable promoters and has required that Galloway make a deposit of $2000 as evidence of good faith.

MANITOWOC, WIS.—The Fond du Lac & Northeastern Electric Railway Company has made application for a franchise to enter this city.

NEW INDUSTRIAL COMPANIES.

THE RICE & BALDWIN ELECTRIC COMPANY, of Hartford, Conn., has increased its capital stock from $10,000 to $20,000.

THE TROY TELEGRAPH CONSTRUCTION COMPANY, New York, has been incorporated; capital, $10,000. Directors: Thomas L. Hughes, L. B. Grant and Ashley T. Cole, New York.

THE THIRD RAIL SAFETY SIGNAL COMPANY, New York, has been incorporated; capital, $25,000. Directors: G. F. Balentine and A. P. Nevin, New York, and Otto Ernst, Larchmont.

THE ADAMS INCANDESCENT LIGHT COMPANY, New York, has been incorporated; capital, $200,000. Directors: Thomas Adams, Jr., Bay Shore; L. R. Adams, New York, and G. J. Adams, Brooklyn.

THE RITER-CONLEY MANUFACTURING COMPANY, Pittsburg, has secured the contract for the building of a large steel stack for the power house of the Manila Electric Railroad & Lighting Corporation, Manila, P. I.

THE ACKERMAN-BOLAND TELEPHONE COMPANY has been incorporated in Chicago with a capital stock of $6000, to manufacture electrical apparatus. The incorporators are Charles Ackerman, J. F. Boland and J. W. Liggett.

THE VORTEX ELECTRICAL FAN COMPANY has been formed at Augusta, Me., to manufacture electrical devices. Its capital stock is $225,000, of which $50 has been paid in. Mr. Howard F. Butler, of Boston, Mass., is president and treasurer.

THE DITTRICK & JORDAN ELECTRIC COMPANY, Cleveland, Ohio, has been incorporated with $12,000 capital stock, by A. R. Dittrick, J. Jordan, W. E. Davis, F. A. Little and A. D. Dittrick. They will do electric railway repair work.

THE COOLEY ELECTRIC PROCESS COMPANY has been incorporated at Augusta, Me., to manufacture electrical machinery and appliances. The capital stock is $50,000. The officers of the company are: President, John F. Cooley, Boston, Mass.; treasurer, Robert Cushing, Brookline, Mass.

THE SHEDD ELECTRIC COMPANY, of Elizabeth, N. J., has filed articles of incorporation, the capital stock being $250,000. The company will conduct a general electrical supply business. The incorporators are: W. H. Peck, J. F. Symes, C. A. Matthews, H. C. Henshaw and H. R. Palmer, all of New York City.

OBITUARY.

MR. JOHN B. O'HARA, associate editor of the *Street Railway Journal*, died at the residence of his brother-in-law, J. G. Hickey, in Rochester, March 13. Mr. O'Hara joined the editorial department of the paper just two years ago. He was born in Rochester on December 10, 1865. After graduating from the public schools he became connected with the *Rochester Herald* and was afterwards appointed associate city editor of the *Post-Express*. Fifteen years ago he went to Chicago to join the editorial staff of the *Western Electrician* and became editor in chief of that paper. This position he occupied for a number of years with marked success. Later he was offered a proprietary interest and business management, with editorial control, of *Modern Machinery*, a monthly paper published in Chicago. He was soon obliged to resign this position on account of failing health, and to take a long vacation. Partially recovering and being of a disposition which would never permit unnecessary idleness, Mr. O'Hara joined the Publication Department of the Westinghouse Companies with headquarters in New York, but after a few months' connection with this company was offered and accepted the position on the editorial staff of the *Street Railway Journal*. Ten years ago Mr. O'Hara was married to Miss Margaret Hickey. After her recent death he attended the body to Rochester where the interment took place, but serious illness followed so soon in his own case that he was unable to attend the funeral in that city. His death occurred just four weeks after that of his wife, and was caused by valvular heart trouble. He is survived by an only son aged eight years, his father and two sisters. Mr. O'Hara possessed the high esteem and respect of all with whom he was acquainted, and especially of his immediate associates who had an exceptional opportunity of learning and appreciating his high character and admirable qualities of mind and heart. He was an associate member of the American Institute of Electrical Engineers.

LEGAL.

JEFFERSON CITY, MO.—The Supreme Court in banc has decided that the charter of Kansas City did not give the city authority to pass an ordinance regulating telephone charges in that city. J. W. Garner, of Kansas City, instituted mandamus proceedings in the Supreme Court against the Missouri & Kansas Telephone Company to compel the company to reduce its rates to the scale fixed by the city ordiance. The writ is denied by the Supreme Court.

VALIDITY OF FRANCHISE.—The Supreme Court of Louisiana has held that the franchise granted in New Orleans to the Consumers' Electric Company is valid. Its syllabus of decision says: "City Ordinance No. 1694, granting to the Consumers' Electric Company the privilege of using the streets and public places for laying of conduits, etc., falls within the scope of section 86 of the city charter as amended, and said ordinance, having been passed in accordance with the requirements of said section, is valid. The furnishing of electric light and energy to private consumers is not a public duty or function, or a utility to become public on terms, within the meaning of section 87 of the city charter as amended."

PERSONAL.

B. H. WARREN.

MR. B. H. WARREN.—The recent election of Mr. B. H. Warren to the presidency of the Allis-Chalmers Company, as noted in our columns last week, renders very timely the publication of a portrait and some biographical data about this well-known engineer and man of affairs. Mr. Warren graduated in the engineer corps at the United States Naval Academy in 1874, and was in active service in the United States Navy at sea and on shore until 1878, when he resigned from the service to find larger opportunities for his energies. From 1878 until 1890 he was with the Hancock Inspirator Company, Boston, Mass., as mechanical engineer, manager of the London office four years and as superintendent six years. From 1890 to 1895 Mr. Warren was manager of the hoisting machinery and pulley block department at the Yale & Towne Manufacturing Company, Stamford, Conn. He went thence, when the business of that department was sold, to the Pratt & Whitney Company, Hartford, Conn., serving temporarily as assistant secretary and treasurer. Mr. Warren was next, from 1896 to 1902, with the Westinghouse Electric & Manufacturing Company, Pittsburg, Pa., as assistant general manager, in charge of manufacturing, for ten months, then as second vice-president, in charge of both the manufacturing and the commercial branches of the business. This is a remarkably wide experience, and a most felicitous preparation also for the duties incumbent upon the president of such a concern as the Allis Chalmers, making apparatus for all the four powers—steam, gas, water and electricity. Mr. Warren assumes his new responsibilities this week, and thus will have a very active part in the successive developments which are raising the Allis-Chalmers Company into an industrial organization of the first magnitude, his marked improvements in methods of manufacture, in works management, in broad plans for increasing output and decreasing expenses, as well as multiplying efficiency, all now having a wider platform for their display than ever before. Mr. Warren, by the way, is a Bostonian. He has also a lovely country-place in Virginia. He is a member and an ex-vice-president of the American Society of Mechanical Engineers; a member of the Society of Naval Architects and Marine Engineers; and a member of the Society of Naval Engineers. He is a member of the University Club, of New York, and of the Engineers' Club. After he has completed his inspection of the Allis-Chalmers Company's works at Scranton, Cincinnati, Chicago and Milwaukee, his offices will be established in the Empire Building, 71 Broadway, New York. It is two years since Mr. Warren severed his Westinghouse connections.

MR. W. STANLEY, JR.—It is understood that Mr. Stanley will not carry out plans recently announced of acting as consulting electrical engineer to the Allis-Chalmers Company, but will confine himself, at least for the present, to experimental work.

MR. ASA M. MATTICE has resigned as chief engineer of the Westinghouse Machine Company and consulting engineer of the Westinghouse Electric & Manufacturing Company, to accept the position of chief engineer of the Allis-Chalmers Company.

MR. H. B. KIRKLAND.—The many friends of Mr. H. B. Kirkland, general sales manager of the American Circular Loom Company, will be pleased to know that he has almost fully recovered from his recent severe illness and is in receipt of many congratulations.

MR. JOHN F. KELLY, of the John F. Kelly Engineering Company, has resigned from the position recently assumed by him as chief electrical engineer of the Allis-Chalmers Company, finding that the responsibility and work involved from his connection with both concerns was more than he could well carry.

MR. CARLOS G. PALACIOS, the chief engineer of the electrical end of the Caracas Gas & Electric Light Company, who has been here for the past month on behalf of his company and also for the La Guayra Electric Light Company, will sail March 19 for Venezuela. Mr. Palacios was the first introducer of American electrical machinery into Venezuela. While in New York he placed through the export commission house of Kates & Bok some $75,000 of orders for various equipment, details of which were noted in our issue of February 13. Mr. Palacios expects to cause the sending here of a number of requisitions, shortly after his return home, for machinery to be installed in various Venezuelan plants owned by capitalists for whom he acts in an advisory capacity.

MR. OSCAR T. CROSBY.—Owing to a prolonged absence in Europe, Dr. M. I. Pupin has not arrived early enough to deliver this month, as already announced, his lecture on the Physics of Wireless Telegraphy, before the New York Electrical Society. The officers of the society have, however, very great pleasure in informing the members that in response to an invitation addressed to him by a number of his friends, members of the society and of the American Institute of Electrical Engineers, Mr. Oscar T. Crosby, E. E., the distinguished engineer and explorer, has kindly consented to deliver a lecture entitled "Things Seen in Turkestan and Thibet," at the lecture room of the American Institute, 19 West 44th Street, Wednesday, March 23, at 8 P.M. Due notice will be issued. Mr. Crosby has returned recently from the mysterious mountain plateau of Central Asia, and his adventures constitute a most fascinating and instructive story. The lecture will be illustrated by some 30 lantern slides, and the officers of the society congratulate their fellow members on this delightful and unexpected supplement to the winter programme, already so notable for its successes. It is a ladies' night.

CARL SCHWARTZ.

MR. CARL SCHWARTZ has been appointed on the staff of the New York Central R. R. electrical engineering department as assistant engineer, and will be connected with the design and erection of the electrical part of the traction power stations. Mr. Schwartz after graduation from the Royal Technical College in Hanover, Germany, entered the Allegemeine Elektricitats Gesellschaft as designing engineer and later was appointed by the Siemens & Halske Company chief engineer of its light and power department in St. Petersburg, Russia, where he designed and erected a number of important low and high-tension power stations and power distributing systems. Mr. Schwartz was with Siemens & Halske for about seven years, and latterly was their general representative for the South of Russia and director of a concern for light and power utilization which he organized with a capital of 4,000,000 rubles, and which controlled stations of 6000 and 1500 horse-power, three-phase. Coming to the United States, Mr. Schwartz visited the works of all important manufacturing companies and the more prominent central stations in order to familiarize himself with the conditions in this country. Concluding to stay in the United States, he accepted a position with the Commonwealth Electric Company in Chicago, where he had charge of the design of the electrical part of the New Fisk Street Station laid out for 14 Curtis steam turbines of 5000 kw each, and into which he introduced a number of new features in high-tension power station design. He was also in charge of the erection of several new substations for 1000-kw rotary converter-units, and a high-tension distributing system of his own design.

MR. S. J. CONDIT, JR., of Boston, was a visitor in New York City last week, on important business.

W. E. BAKER & COMPANY, electrical and mechanical engineers, have moved their offices from 170 Broadway to 27 William Street, New York.

DR. LEE DE FOREST, of the American De Forest Wireless Telegraph Company, is to lecture before the Franklin Institute on March 31 on wireless telegraphy.

MR. F. P. FISH, president of the American Bell Telephone Company, recently arrived in San Francisco on a visit, and was entertained extensively by prominent citizens.

MR. E. A. WAKEMAN, formerly with the Batavia, N. Y., Consolidated Gas & Electric Company, has become superintendent of the Glens Falls, N. Y., Gas & Electric Company.

MR. ROBERT McCULLOCH, a veteran street railway manager, has returned to an old "stamping ground," having just been elected second vice-president of the St. Louis Transit system.

MR. G. E. BENNETT, formerly assistant manager of the Chicago office of the Nernst Lamp Company, has been appointed district sales manager of that company, with offices at 17 West Mohawk Street, Buffalo, N. Y.

MR. C. L. EDGAR, president of the National Electric Light Association, was at headquarters in New York City last week, busily engaged making preparations for the Boston convention next May. A large and interesting programme is already promised.

MR. CLARENCE J. MESSER, of the United Telpherage Company, of Boston, will deliver a lecture on telpherage or the modern electric art of transporting material aerially on a wire track, etc., before the Franklin Institute, Philadelphia, on April 14.

MR. JAMES I. AYER, general manager of the Simplex electric heating department, was a visitor to New York last week, and had a variety of most interesting data as to new heating problems and successful work, with which he has been dealing quite recently.

MR. CORNELIUS C. VERMEULE, consulting engineer, 203 Broadway, New York, has gone to Cuba in connection with the construction of the extensive lighting and traction system in and around Cienfuegos. He expects to be back by the end of the month.

MR. CHARLES RICOU, electrical engineer, etc., connected with the central station at Hanoi, Tonkin, French China, and consulting engineer of the Tramways Company, will be glad to receive catalogues of electrical apparatus bearing upon various applications.

MR. W. S. DORAN, at one time associated with the Worthington interests and who now is prominently identified with the sales department of the British Westinghouse Electric & Manufacturing Company, Limited, sailed for Europe March 1, after a short visit to this side.

MR. W. D. RAY has severed his connection with the Westinghouse Traction Brake Company as representative for the Central States, and has now entered the steam specialty field. He will represent several well-known manufacturers in the sale of high grade specialties, with offices at 312 Electric Building, Cleveland, O.

MR. HERBERT LAWS WEBB, of whom we published an illustrated biographical sketch in our issue of February 20, has taken offices in London as a telephone engineer, etc., at 35 Old Queen Street, Westminster. He will be glad to receive there catalogues from American manufacturers of telephone and telephonic appliances.

MR. JAMES STEWART, under whose supervision the colossal works at Trafford Park, near Manchester, of the British Westinghouse Electric & Manufacturing Company, Limited, were constructed and who latterly built in record time a number of large power houses for which the company secured the contracts, is to locate permanently in New York. He will open offices very shortly and will engage in general contracting work.

MR. C. O. MAILLOUX, of New York City, lectured before the engineering students of Delaware College, Newark, Del., Thursday and Friday, March 3 and 4. His general subject for all the talks was "Central Station Practice." This had been arranged by the Department of Mechanical and Electrical Engineering for the purpose of bringing the class room work more closely in touch with engineering practice. Mr. Mailloux has lectured before Lehigh, Cornell, Harvard and other universities, where the value of his suggestive talks to the students has been highly appreciated.

GEN. FRANCIS V. GREENE, general manager of the Ontario Power Company, spoke before the Niagara Club, at Niagara Falls, on March 4, on "The Future of the Niagara Frontier." He pointed out very forcibly that the improvement of the Erie Canal would mean a remarkable development of that section and the restoration of the Empire State to the supremacy in the industrial world He said that cheap power, generated at the Falls, cheap raw material and railroad and lake transportation, would bring about the establishment on the Niagara frontier of large industries in steel and iron electrochemical products, milling and various textile lines.

MR. J. G. WHITE, head of the engineering firm of J. G. White & Company, of New York, gave a dinner at the University Club last week to Secretary of War Taft, formerly governor of the Philippines. Mr. White is now building 40 miles of trolley road in Manila, and Mr. Taft is anxious also to interest American capital in steam railroad enterprises in the Islands. A distinguished party met Mr. Taft, including Mr. Elihu Root, late Secretary of War; and members of the leading banking houses of New York and the Eastern States. Mr. Oscar T. Crosby, who has recently returned from a journey through Thibet, was one of the speakers.

MR. EDWIN REYNOLDS.—Milwaukee newspapers state that Mr. Edwin Reynolds, consulting engineer of the Allis-Chalmers Company, was unanimously tendered the position of chief engineer of the committee of awards of the Louisiana Purchase Exposition at St. Louis. He declined the honor. His final decision was given to a special committee of machinery exhibitors who went to Milwaukee from St. Louis last week for the express purpose of urging him to accept the plaoe, one of the most honorable and important positions connected with the expositibn. In declining the honor, Mr. Reynolds informed the committee, as he had done before by letter, telegraph and telephone, that he did not feel that he could undertake the responsibility at this time, largely on account of his advancing years and the time it would require during the entire exposition. Out of a total of thirty-three votes by the largest machinery exhibitors in the world, who will have extensive exhibits at St. Louis, Mr. Reynolds received thirty votes on the first ballot for the position of chief engineer of the committee of awards. Later he received the unanimous vote of the exhibitors. A salary of $10,000 was voted to go with the position. Then the exhibitors started to induce him to accept. From the beginning he told the committee that he did not feel that he could undertake the work, because if he did he would not neglect it, and would only sign certificates after becoming personally convinced of the justice of the awards, and he did not now feel equal to the undertaking.

Trade Notes.

EXHAUST HEADS.—The Burt Manufacturing Company, Akron, Ohio, has sold the Jones & Laughlin Steel Company a 30-inch exhaust head for its plant at Pittsburg, Pa.

THE ELECTRIC APPLIANCE COMPANY, Chicago, selling agents for Zenith lamps, is sending out a handsome descriptive catalogue of these lamps, to all who failed to receive one on the first distribution.

KELLER, PIKE & COMPANY, of Philadelphia, electrical contractors and engineers, have opened an office in Baltimore, at 211 North Calvert Street. This office will be in charge of Mr. John S. Dobler, of Baltimore, whose training, experience and connections especially fit him for this position.

THE DALE COMPANY, New York City, is very busily engaged putting on the market its new Dale wireless cluster, for multiple or series work. It makes up in very compact and handsome form and is cheap and durable. Mr. John Dale is already happy over a rushing business in all the forms of this new specialty.

THE STERLING ELECTRIC COMPANY, Lafayette, Ind., has just placed upon the market two new subscribers-station protectors for the protection of telephones, one consisting of heat coil and carbons and one of heat coils only. They are reported to be very efficient protectors and recommend themselves to the trade on account of merits and low cost.

THE CALCULAGRAPH COMPANY has issued a 16-page pamphlet speaking of the changes in appliances for calculating time. The story begins with the sand glass, talks about the establishment of clocks and their peculiarities, and winds up, of course, with a description of the Calculagraph as a time keeper and a calculator. The catalogue is printed in two colors on a good quality of paper and contains copies of testimonial letters from various users.

TESTING PLATE FOR ENGINES.—One of the most interesting features of the new plant now being erected by the B. F. Sturtevant Company at Hyde Park, Mass., is an elaborate testing plate for its engines. With an output of a thousand engines or more per year, this is the essential climax of a careful system of manufacture and testing. The plate, or more properly the plates, will be supported upon a series of heavy parallel walls between which steam and exhaust pipes are carried so that at almost any point in the entire area of the floor, measuring about 30x60 feet, steam and exhaust connections may be made to any engine. Testing facilities will be provided, and a transfer crane overhead will make it very simple to locate or remove the engines. The same crane will transport them to the packing department, and thence load them directly upon cars which traverse the end of the building.

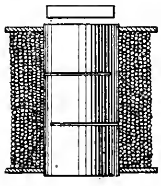
Record of Electrical Patents.

UNITED STATES PATENTS ISSUED MARCH 8, 1904.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., New York.]

753,839. TROLLEY WIRE FINDER; William Barnhurst, Dallas, Tex. App. filed June 1, 1903. A pulley pivoted under the trolley wheel and carrying a guiding fork, is rotated by a cord to throw the fork into operative position.

753,866. BRUSH HOLDER FOR ELECTRICAL MACHINES; William H. Foot, Wilkinsburg, Pa. App. filed June 24, 1903. A number of individually actuated brushes of such construction that their position on the rocker arm may be easily and quickly reversed when it is desired to reverse the direction of rotation of the armature.



753,879.—Electromagnet.

753,872. ELECTRIC PRINTING MACHINE; George S. Gallagher, New York, N. Y. App. filed April 29, 1903. Details of construction of a telegraph printer.

753,875. ELECTRICAL MANUFACTURE OF IRON ALLOYS; Gustave Gin, Paris, France. App. filed July 7, 1902. (See page 569.)

753,879. ELECTROMAGNET; Willis D. Gregory, Pittsburg, Pa. App. filed April 9, 1903. The fixed core of the magnet is structurally interrupted in one or more planes transverse to the direction of the magnetic lines, with the object of producing an electromagnet which will quickly discharge itself.

753,881. ELECTRIC SNAP SWITCH; Gerald W. Hart, West Hartford, Conn. App. filed April 18, 1903. Details.

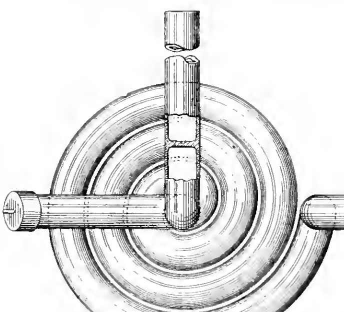
753,916. SHUNT RESISTANCE; Geo. W. Richmond, Pittsburg, Pa. App. filed July 10, 1903. A ribbon resistance set on edge and supported by blocks having slits into which the ribbon fits.

753,935. INCANDESCENT ELECTRIC LAMP; Herbert M. Taylor, Hamilton, Canada. App. filed Sept. 2, 1902. The lamp has an internal conical reflector around which the filament passes, for the purpose of diffusing the light.

753,944. TRANSFORMER CASE; Wm. L. Waters, Milwaukee, Wis. App. filed March 5, 1903. Tubular passages are formed in the casing to permit of a circulation of air for cooling purposes.

753,999. CONTROLLING VALVE; Asa H. Mosher, Westfield, N. J. App. filed Feb. 25, 1903. Details.

754,005. FIRE ALARM OR TEMPERATURE ANNUNCIATOR; John A. Olson, Minneapolis, Minn. App. filed Aug. 3, 1903. An index moving over a dial closes different alarm circuits at different positions on the dial.



754,079.—Spiral Vacuum Tube for Therapeutic Purposes.

754,018. ELECTRIC SAD-IRON; Geo. J. Schneider, Detroit, Mich. App. filed Aug. 11, 1903. The end of the flexible conductor leading to the binding posts of the iron is supported by passing through an opening in the handle just before it reaches the binding post.

754,030. ALARM ATTACHMENT FOR LINOTYPE MACHINES; Geo. L. Venable, New Brunswick, N. J. App. filed April 11, 1903. An electric alarm indicating to the operator when the molten metal in the pot reaches a certain level.

754,075. GAS BURNER; Wm. Kohn, Brooklyn, N. Y. App. filed July 6, 1903. Details.

754,079. SPIRAL VACUUM TUBE FOR THERAPEUTIC PURPOSES; Robert Machlett, New York, N. Y. App. filed Jan. 26, 1904. A flat spiral with the electrode fixed in the outer and inner ends respectively, designed to bring the rays near to the surface of the body and to distribute them over a large surface.

754,081. BATTERY-STOPPER; Albert Muller, New York, N. Y. App. filed Oct. 24, 1903. (See page 569.)

754,111. JUNCTION BOX FOR ELECTRIC WIRES IN BUILDINGS; Boyd W. Allen, Boston, Mass. App. filed Dec. 12, 1903. The bottom of the box is a thick body of insulating material in which the nipple for the fixture is embedded, thus avoiding the use of nails or screws passing behind the box.

754,114. PROCESS OF PREPARING ELECTRODES; George Jones Atkins, Tottenham, England. App. filed Oct. 6, 1903. (See page 569.)

754,123. INSULATOR PIN; James H. Bullard, Springfield, Mass. App. filed Oct. 26, 1903. A metal pin comprising a series of longitudinal webs joined together and forming grooves for a plastic material, to aid in holding the insulator in place.

754,124. ELECTRIC MOTOR; David P. Burdon, Jacksonville, Fla. App. filed July 13, 1903. An oscillating motor having a switch for shifting the current from pole to pole.

754,133. SYSTEM OF ALTERNATING-CURRENT DISTRIBUTION; Edwin R. Gill, New York, N. Y. App. filed Sept. 5, 1900. As a means for producing auxiliary current-waves out of phase with an original single-phase current in a main circuit, an auxiliary circuit having a self-induction approximately equal to that of the main circuit, a condenser and means for alternately charging the condenser from the main circuit during rise of potential in the circuit, and discharging the condenser into the auxiliary circuit, whereby the main and auxiliary circuits are made to carry perodic currents of different phases and common periodicity.

754,147. APPARATUS FOR ELECTRICAL PRODUCTION OF NITROGEN OR OTHER COMPOUNDS; Josef Von Kowalski and Ignaz Moscicki, Freiburg, Switzerland. (See page 569.)

754,152. SIGNALING APPARATUS; Otto Luddeckens, Breslau, Germany. App. filed Feb. 21, 1903. A signal for mines in which the engine room receives the signals passing between the pit bottom and the mouth and the engineer is able to prepare in advance for signals coming direct to him from the mouth of the mine.

754,208. ELECTRIC SIGNAL; Joseph E. Feller, Brooklyn, N. Y. App. filed April 24, 1902. Relates to the construction of instruments in which the person signalled may indicate to the person signalling if the signal is properly received.

754,235. EXTENSION FIXTURE FOR INCANDESCENT ELECTRIC LAMPS; Conrad H. Titel, Meriden, Conn. App. filed May 6, 1903. A spring drum and ratchet arrangement for taking up and letting out the conductor and the mechanical support for the fixture.

754,261. OZONIZER; Alexander Vosmaer, Nieuwersluis, Amsterdam, and Adriaan Lebret, Utrecht, Netherlands. App. filed Sept. 11, 1902. (See page 569.)

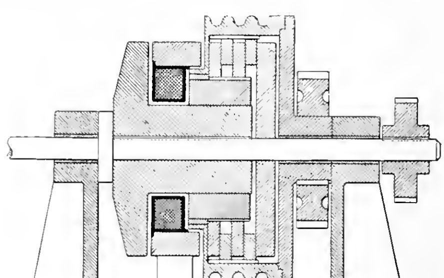
754,291. MAGNETIC CLUTCH; Arthur C. Eastwood, Cleveland, O. App. filed Jan. 26, 1904. Interleaved metal plates are caused to frictionally engage by a magnet placed to act upon them.

754,294. HORSE BLANKET; Ida J. Foglesong, St. Paul, Minn. App. filed Sept. 17, 1903. Electric heating wires are threaded through the blanket for the purpose of sweating the animal.

754,359. APPARATUS FOR STOPPING RAILWAY TRAINS FROM THE LINE AND FOR SIGNALING PURPOSES; Bernardus A. J. Van Der Hegge-Zijnen, Hanover, Germany. App. filed May 26, 1902. An arm is projected from the roadway to strike an air-brake valve of the train to set the brakes. The contact between the parts closes a circuit to notify an operator at a station of the event.

754,362. RAILWAY SIGNALING SYSTEM; Henry Bezer, Westfield, N. J. App. filed Oct. 16, 1901. Various features of a block system in which the rails of the track are the only conductors from one end of the block to another.

754,363. RAILWAY SIGNALING SYSTEM; Henry Bezer, Westfield, N. J. App. filed Oct. 16, 1901. A modification of the preceding patent.



754,291.—Magnetic Clutch.

754,378. ELECTRIC SWITCH; Norman Marshall, Newton, Mass. App. filed June 27, 1903. Improved devices for transmitting movement from the spindle to the catch which holds the spring until it has been fully put under tension.

754,379. ELECTRIC SWITCH; Norman Marshall, Newton, Mass. App. filed Oct. 6, 1903. Details.

754,380. ELECTRIC SWITCH; Norman Marshall, Newton, Mass. App. filed Oct. 6, 1903. Details.

754,391. BURGLAR ALARM; Freeman C. Robinson and James E. Green, Council Bluffs, Iowa. App. filed Nov. 26, 1901. A pair of contacts are attached to the bolt of a safe and while the bolt is in its locked position, rest upon a plate of insulating material, but as soon as the bolt is withdrawn, they drop onto a metal surface, closing an alarm circuit.

754,397. ELECTRIC CLOCK; Geo. S. Tiffany, Brooklyn, N. Y. App. filed Nov. 30, 1901. Details.

754,402. FAULT LOCATOR FOR ELECTRIC CABLES; Daniel E. Wiseman, Spokane, Wash. App. filed Aug. 3, 1903. A Wheatstone bridge in which the scale of resistance is read directly in units of length.

Electrical World and Engineer

THE CONSOLIDATION OF "THE ELECTRICAL WORLD" AND "ELECTRICAL ENGINEER."

VOL. XLIII. NEW YORK, SATURDAY, MARCH 26, 1904. No. 13.

ELECTRICAL WORLD AND ENGINEER.

Published weekly by the

McGRAW PUBLISHING CO.

114 LIBERTY STREET, NEW YORK.

TELEPHONE CALL: 7605 CORTLANDT. CABLE ADDRESS: ELECTRICAL, NEW YORK.

EDITED BY T. C. MARTIN AND W. D. WEAVER.

Great Britain and Ireland	25 shillings
Germany	25 marks
France	31 francs
Single copies	.10

Remittances for foreign subscriptions may be made through our European office.
In requesting your address changed give OLD as well as new address.

Entered as second-class mail matter at the New York Post Office.

NEW YORK, SATURDAY, MARCH 26, 1904.

CONTENTS.

DREAMS THAT COME TRUE.

It is worth pointing out at this juncture, when the Union Engineering Building has become a certainty, that the idea has haunted the minds of engineers and scientists for at least a quarter century past. At the very outset of the American Institute of Electrical Engineers in 1884, the project was taken up, and as that body was then enjoying the hospitality of the Civil Engineers, it was under the roof of the Civils that it was more frequently discussed than anywhere else. There were in fact committees on the plan in those early days, but after all was said and done, the thing fell through, although everybody admitted its desirability. The times were not ripe, nor had the growing needs of the various national bodies given a real urgency to their search for a way of solving the difficulties. The project has now attained finality in a very desirable shape, and those who have watched its fate, with waning and waxing hopes and fears for two decades past, can once more rest assured and be reaffirmed in the conviction that a great idea never dies, but should be persisted in and advocated until its merits win out.

PETER THE PILGRIM

Following the excellent introductory notes of Brother Potamian in the two preceding issues, we print elsewhere in this issue a translation in full, specially made for our columns, of the epistle of Petrus Peregrinus. The Latin text used is that of Gasser, A.D. 1558, a copy of which rare work is in the Wheeler collection of the Library of the American Institute of Electrical Engineers. The letter of Pierre de Maricourt, commonly called Petrus Peregrinus (from having made a pilgrimage to the Holy Land), is the first great landmark in the domain of magnetical philosophy, and is rich in magnetic thought and suggestiveness. True, there have been writers from Thales and Lucretius down to Neckam and Roger Bacon, who wrote about the lodestone; but none of them stopped to investigate seriously its known properties or discover new ones, still less to devise means of applying them to the welfare of mankind. The credit of having done this and done it on an extensive scale, belongs unquestionably to Peregrinus, the Gallic friend of Friar Bacon, and at the same time the great magnetical man of the Middle Ages. His letter on the magnet, written in camp amid the din of war and the exigencies of his engineering duties, shows him to have been uncommonly gifted for original work and for delving deeply in the arcana of nature. In his researches he brought to light a great body of facts about the lodestone, tested them in numerous ways, co-ordinated them, and described them in due sequence in his famous "Epistola ad Sigerum," A.D. 1269.

If Peregrinus was a hard thinker and persistent worker, he was also a resourceful man in turning his discoveries to practical account. It may be held that Neckam knew of the pivoted needle before him; but if, after construing the Abbot's *acum jaculo superpositam* to mean that the support was the pointed end of an ordinary dart, we turn to the second part of the "Epistola," we will find in Chapter II a detailed account of the sharply pivoted needle of Peregrinus and an unequivocal statement of its use at all times in navigation. His magnetic motor is a startling conception for so early a period as the thirteenth century. We cannot but admire the ingenuity of the contrivance even if we do smile at the naiveté of the enthusiastic inventor, who flattered himself with the delusion that he had really contrived a perpetual motion wheel—little suspecting that he was realizing in himself his own words: "I have seen many persons vainly busy themselves and even become exhausted with much labor in their endeavors to invent such a wheel."

Singularly enough, it was this selfsame harmless wheel that stirred up to the full the wrath of Gilbert when, forgetful of all Christian precepts, he used such unparliamentary language as "May the gods damn all such sham, distorted works which do but muddle the minds of students." Nevertheless, the writer of this invective was greatly indebted to Peregrinus, whose terminology he adopts and whose "terella" experiments he repeats. It is true that Gilbert refers five times in his "De Magnete," A. D. 1600, to this letter of A.D. 1269, but all that his gratitude inspired him to write of it is that it is "a pretty erudite work for its time." In reading this half-hearted admission, we must bear in mind that the philosopher of Colchester was as sparing in meting out praise as he was liberal in his censures and forcible in his denunciations.

Two works of comparatively recent date have it that Peregrinus, while emphasizing the attractive virtue of the lodestone, nowhere mentioned magnetic repulsion. This must be a *lapsus calami* and nothing more, for in Chapter VI we read: "Know then that this is the law: The north pole of the lodestone attracts the south pole of another, while the south pole of the one attracts the north of the other. Should you proceed otherwise and bring the north pole of one near the north pole of another, the one you hold in your hand will seem to put the floating one to flight. If the south pole of one is brought near the south pole of another, the same will happen." The law of repulsion is as explicitly stated here as it is clearly demonstrated.

As Others See Us.

We have often discussed American engineering education in these columns—so often that we should hesitate to bring it again before our readers were it not for the paper read last month before the Institution of Electrical Engineers, which gives a transatlantic view of our virtues and shortcomings too valuable to be lightly passed over. The author, Dr. R. M. Walmsley, spent three months last year in investigating our engineering schools of various types, and succeeded in gathering an amount of practical information which we have not seen equalled in any similar investigation. And we may congratulate ourselves that the conclusions were of a flattering nature as a whole, especially in comparison with British conditions. Not only is the character of the engineering instruction upon the whole higher here than abroad, but the discrepancy in the number of students is something startling to the last degree. Dr. Walmsley found in sixteen of our prominent institutions 1,371 students in engineering courses who had been more than three years in attendance, while the latest available report in Great Britain showed but 56 students in the corresponding class. This difference does not so much indicate lack of facilities as difference in aims. Among first year and second year students, the comparison is upon more even terms, the truth being that with some distinguished exceptions the British technological schools are substantially what we would know here as trade schools, from which the pupils frequently pass into their technical pursuits without waiting to complete the course. This difference is emphasized by the undoubted fact that the average student material here and in Canada is drawn from a relatively better class than in England. As Dr. Walmsley remarks, the engineering professions there have to come into severe competition for personnel with the Army and Navy, the Indian and other public services.

He might have added that engineering is generally considered as too deucedly near to trade to attract on the whole a high grade of student material. The early efforts at scientific education in technical schools even in this reputedly democratic country suffered not a little from the same source. It would not have been quite a polite thing to say at the time, but twenty-five years ago engineering did not have its present standing among the professions, and the old classical colleges unquestionably got the pick of the student material. These social differences reach even further. We have had in this country a great many men in high commercial and technical positions who have risen from the ranks, and we are justly proud of them; but it is undeniable that the activities of our country for the past fifty years have been in greater proportion directed by college-bred men than in any other country in the world, with the possible exception of Germany. The result is that those who now direct our activities are in more than usual close sympathy with education, technical and other, and appreciate the advantage of drawing into their service young men with the best possible training. Hence, the conditions noted by Dr. Walmsley in regard to the demand for technically-trained men in American manufacture. The moral can in no wise be better pointed out than by mentioning that Charles William Eliot narrowly escaped becoming the manager of a cotton mill the year before he was elected president of Harvard College. We do not wish to be considered discouraging, but we do not see how technical education in England can be put firmly upon its feet until certain points of view are very considerably modified. When the well-to-do and well-born young Englishman heads for the engineering profession as freely as he heads for the Army or the Church, things will begin to go differently.

Dr. Walmsley, in way of criticism, puts a keen analytic finger on the very points which we have often recognized as weak spots in our technical education. His many conversations with American manufacturers brought out as the most general criticism "that in many cases the training is too superficial and too apt to overload the student with a large and confused assortment of facts instead of training him in principles, this being in a large measure due to attempts to deal in too much detail with a crowd of subjects, especially in the last year of the course." And with respect to one egregious fad in recent education, Dr. Walmsley remarks: "It is a matter for serious consideration whether the excessive amount of time given to manual work in the manual training schools has not been dearly purchased at the expense of starving the time which should have been given to mental training." We wish that some of our strenuous and solemn-visaged educators who spell themselves in large capitals and have so little sense of humor as to take themselves seriously, would cut out these two quotations and paste both into their hats. As things are at present, the higher technical institutions are busy for no inconsiderable part of the course in stopping the gaps left by kindergarten foolishness of various sorts in the primary and secondary schools. They admit students at eighteen or nineteen years of age and then spend the better part of two years in teaching them the elementary English, mathematics and modern languages that have been neglected in the secondary schools, to make room for nail-driving, music, painting and emasculated physiology. It is vast credit to the technical schools that in a four-years' course they can turn off the material they do in spite of inefficient preparation. Our English friends in trying to build up a system of technical education will at least have less foolishness to contend with at the start. The thing most needed over there, however, is the sympathetic assistance of the great universities. So long as they hold aloof from directly encouraging technical students, the tremendous weight of their centuries of social influence will stand against improvement.

The Telephone Repeater.

To one who might undertake to study the course of invention by reference to Patent Office records, the telephone repeater, from its numerous entries, would appear to be at least holding its own in the rapid progress of telephonic development. As a matter of fact, all the work of inventors in this branch during the past twenty years or more has thus far brought forth absolutely no practical result. This condition appears to indicate that in this perhaps more than in any other department of invention, the inventor is prone to apply for a patent without having first determined by practical trial if his apparatus will really in actual work over long-distance lines perform the functions for which it is devised; and in the present case this is the more inexcusable from the fact that opportunities for such a trial are nowadays within easy reach, and involving small expense either in apparatus or test. A successful telephone repeater is the great need in telephony, and its inventor would be abundantly rewarded materially, which undoubtedly accounts for the scores of patents that have been issued on "telephone repeaters"; yet of all these we do not know of one that has been put to public test on a circuit of sufficient length to demonstrate its capabilities. The uniformly negative results thus far may, however, be ascribed, not to any undue lack of inventive skill, but to the enormous difficulties in the way of renewing the energy of voice currents without affecting their speaking characteristics; that is to say, the difficulty of strengthening in absolutely equal proportion each element of a current varying enormously in frequency and in amplitude. The introduction into a circuit of repeating apparatus is in itself apt to destroy the speaking characteristics of the current to be repeated, even before it undergoes any supposed process of reinforcement. The futility of effort thus far indicates that the telephone repeater, if it is ever realized, will be based upon some radical discovery, perhaps second only to the discovery of the telephone itself. In the meantime, the record of past failure indicates that effort will be wasted in endeavors to realize a telephonic repeater through mere mechanical combinations of parts and without reference to the fundamental physical principles governing the generation and transmission of the telephonic current.

THEORIES OF WIRELESS TELEGRAPHY.

Our correspondence columns last week contained an interesting letter from Prof. A. Blondel on the subject of wireless telegraph theory. A few years ago, in fact as recently as 1900, a great diversity of opinion existed as to the nature of the waves employed in wireless telegraphy, and as to their mode of propagation. Now, however, there is very little difference of opinion outstanding, and the latest stones in the structure of the theory have been laid by the papers of M. Blondel. The gist of the whole theory lies in the recognition that the wireless telegraph waves are essentially the same as the waves produced and studied by Hertz, except that a sheet of conducting material, namely, the surface of earth or sea, occupies the midplane of the system, and that one-half of the system, i. e., that beneath the conducting plane, is abolished. The semi-system then remaining above the conducting sheet travels just as though the sheet were not there, so long as the sheet remains in the midplane. As soon as it bends out of the midplane, as by the curvature of the earth in the telegraph case, the pure Hertzian system becomes modified by the presence of the sheet, to the extent of bending over, or conforming to, or being guided by the sheet, and the waves, therefore, depart from their original rectilinear path. Add the secondary effects of attenuation at the surface of the earth due to imperfect conductivity, the tearing of gaps or rents in the wave by the presence of local conductors on the earth, such as structural steel buildings, lightning conductors, or receiving antennæ, as well as the possible influence of conducting strata high in the atmosphere, and the Hertzian wave theory applies at once to the wireless telegraph case. The views that have been expressed by Messrs. Blondel, Fessenden and ourselves are all in essentially complete accord.

Perhaps the easiest picture to form, in the mind's eye, of a wireless sheet wave is to consider a net, like an enormous seine or fishing net, invisible to the eye, emitted from the sending antenna and running out from it at the speed of light in all directions, spreading as it runs. If the cord of which the net is made is barbed, so as to mark the direction of weaving, the positive side of the wave will differ from the negative in the directions of these barbs. After a few wave lengths from the origin, the net will occupy the form of an inverted hemisphere. At the ground the horizontal lines, or the warp, will represent magnetic flux lines; while the vertical lines, or the woof, will represent electric lines. The net propagates itself everywhere, at light speed, in a direction perpendicular to the surface. It tries to get away from itself sideways. Every cord in the net extends elastically from the tension due to moving sideways. The net is constantly increasing in dimensions, and in the length of each cord as it advances. But no cord moves at any time in the direction of its own length. That is, the pull along any cord in one direction is exactly balanced by the pull in the opposite direction, so there can be no resultant force, or component of force, along any cord, tending to move it longways. All the pull which gives rise to movement makes each cord travel sideways, or perpendicularly to its length and to the net.

There is this curious analogy between the electromagnetic net and a material net moving over the ground. If the ground were absolutely smooth and perfectly frictionless, a vertical fishing net carried over the ground so that the lower edge just touched would not be bent from the vertical by the contact. This would correspond, in the case of the electromagnetic net, to a perfectly conducting surface. There would be no bending in at contact with the ground. But if the net were dragged over a rough surface it would be bent, at the lower edge, out of the vertical plane by the friction. This corresponds to imperfect conductivity in the electric case; the net becomes frictionally bent back at the surface, to a greater or less extent, and the wave at the ground, moving always perpendicular to its own surface, runs into the ground, thereby dragging part of the net after it and bringing about extra attenuation of the fibres.

Moreover, if the material net were carried over posts or obstructions at a sufficiently rapid rate, rents would be torn in the bottom of the net, and at the gaps the edges of the net would be bent back by the contact, or out of the perpendicular plane. So in the electric net, a brick wall is no obstruction, but a metal rod or a lightning conductor takes the part of a post in the material case, and tears a gash out of the net. The edges of the net at the gash are, however, bent back as they tear, and as the net moves on the edges take a lateral or sideways motion, in addition to the regular advancing motion, tending to draw the edges of the rent together, and seal up the gash, at the same time drawing upon the net as a whole to do this, and executing the repair with some general attenuation. The electric net, being bent at the gash out of the regular shape, can mend itself automatically by taking a component of force and motion that would correspond to longways propagation in the uninjured net. Assuming that we have a clearly defined working theory of the nature of wireless telegraph waves, we need convenient means of experimental exploration in the air and open field in order to make rapid progress in our knowledge of the subject. What we want is a measuring instrument so sensitive that when connected in the middle of an exploring rod observations can be collected in many different directions and at many different elevations.

Incandescent Lamp Patent Infringement Suits.

The Edison Electric Light Company, now a part of the General Electric Company, has instituted suit against 15 manufacturers of incandescent lamps and ten supply dealers, for infringement of two patents relating to means for exhausting lamps, and one patent on a detail relating to leading-in wires. The two first-mentioned patents are that of Malignani on the method of chemically completing the exhaustion of lamp bulbs and an improvement thereon patented by Mr. John W. Howell. The third is an Edison patent, which provides for sealing in glass, the junction between the platinum and copper leading wires, these wires being welded and the glass then squeezed around them from a piece of tubing. It is claimed that by this method of sealing the junction in glass any danger of the wire working up and down and causing air leaks is obviated. The date of the Malignani patent is April 16, 1895, the number being 537,693; the Howell patent, No. 726,293, is dated April 28, 1903; and the Edison patent No. 444,-530, is dated January 13, 1891.

Use of Electricity in Mines.

The growing use of electricity in mines in England led the British Home Secretary to appoint a Departmental Committee to consider and report on the subject; and the report has recently been published. The committee state the following as the general principles which they consider should govern the employment of electricity in mines:

1. The electric plant should always be treated as a source of potential danger.

2. The plant, in the first instance, should be of thoroughly good quality, and so designed as to insure immunity from danger by shock or fire; and periodical tests should be made to see that this state of efficiency is being maintained.

3. All electrical apparatus should be under the charge of competent persons.

4. All electrical apparatus which may be used when there is a possibility of danger arising from the presence of gas should be so enclosed as to prevent such gas being fired by sparking of the apparatus; when any machine is working every precaution should be taken to detect the existence of danger, and on the presence of gas being noticed, such machines should be immediately stopped.

In regard to (1) and (2) they point out that under the peculiar conditions existing in mines, no absolutely safe voltage limit can be stated. Under the circumstances they have decided, on grounds that have been already recognized in Germany, that with the adoption of all reasonable safeguards a fairly high pressure has advantages, even from the point of view of safety, over a uniformly low pressure. With this end in view, the voltage to be used in-bye is to be the medium standard adopted by the Board of Trade, namely, 650 volts. The main thing is that electricity at any voltage should be recognized as possessing very great elements of danger and treated accordingly. That all electrical apparatus should be under the charge of competent persons will meet with general approval. By far the greater proportion of accidents arising from the firing of shots have been caused by disregard of this rule. As to the working of coal cutters in places subject to firedamp, the committee consider, largely as a result of experiments made, that it is necessary to enclose the entire motor in a flame-tight cover. One important result of these experiments was to demonstrate the possibility of overcoming the heating of the parts due to ironclad construction by ventilating the machine through the armature bearings on the same principle as a Davy lamp.

The committee have adopted the view that all permitted explosives should be fired by electricity, and that the armored covering of all protected cables should be earthed. The first of these ordinances says the British *Colliery Guardian*, will be generally approved, a similar rule having been adopted in Lancashire for some years. Accidents that have occurred with electrically-fired shots have, in almost every case, been caused, not by the electricity but by carelessness or insubordination, and where the system has been efficiently carried out, the result has been a great reduction in the number of miss-shots and a general saving all around. With regard to the second point, there are no doubt many experts who do not approve of the earthing of the armoring of a cable, but as the question is not one of cost and both systems have their advantages, such a dispensation, for the sake of uniformity, should not be objected to.

In concluding their report, the committee suggest that the rules they have drafted should be introduced immediately. A very important reservation from the colliery owners' point of view is that giving the inspectors discretion to revise existing installations. Other provisions are those enabling an inspector to dispense with any rules in any case in which the special circumstances appear to him to render such exemption necessary, and providing for arbitration, as in the enforcement of special rules where any difference of opinion may arise between an inspector and an owner as to any requirement under the same section.

Finsen Light Treatment.

United States Consul Frazier, of Copenhagen, Denmark, reports that in the Finsen Medical Light Institute, now a State sanitarium, 1,367 cases had been treated up to May, 1903, by the Finsen rays. Of these most were lupus vulgaris and in about 1,000 cases the best results had been attained, so that "in most cases one may count definitely upon a cure," to use the official language.

Seventy-five American doctors went to Copenhagen last year expressly to visit the Institute from all sections of the United States. Many of them purchased "Finsen lamps" with a view to establishing institutes for the treatment of skin diseases by the Finsen method. There were eight patients at the time of the report from various parts of the United States. Most of them assert that they were under treatment for years in the United States and employed eminent specialists in various centers of population at home, but that they were unable to secure a satisfactory diagnosis of their affliction; that the various specialists consulted did not agree; and that after years of discouragement and suffering, having heard of the Finsen light treatment they went abroad. Of the eight American patients it appears that all but one had their cases diagnosed satisfactorily at once upon reaching the Institute and have been given hope of final recovery. The doctors at the Institute are extremely conservative and never promise to effect a cure; but the records show that in a majority of cases where sufferers have been encouraged by being admitted as patients cures have been effected. In the one case of the American patients where the physicians have not yet determined whether they can give relief, it appears the patient is suffering from a rather deep-seated cancer, and the Finsen rays do not cure any but the more superficial cancers.

This report does not pretend to discuss the Finsen treatment in detail. It consists of the application to the diseased part of electric arc light, concentrated by a series of lenses and filtered through distilled water, which process of filtration removes the heat rays, but preserves the violet, ultra-violet and blue rays, the chemical and bacterial effects of which are such as to destroy the disease germs of lupus vulgaris and various other skin diseases, curing the diseases apparently for all time.

There are large Finsen institutes in various centers, notably in London, Paris and Berlin, but it is natural that all look to Dr. Finsen and his able assistants at Copenhagen for leadership.

St. Louis Headquarters N. E. L. A.

Mr. James I. Ayer, the progressive and efficient chairman of the Committee on Relations with Kindred Organizations of the National Electric Light Association, announces that arrangements have been made by which the Association will have permanent headquarters at the St. Louis World's Fair, consisting of a railed enclosure furnished with chairs, a convenient desk, stationery, etc., for the use of its members. The office will be in a section used also for an Edison Historical Exhibition, the headquarters of the Association of Edison Illuminating Companies and the headquarters of the American Institute of Electrical Engineers. Members will undoubtedly find this agreeable for a meeting point and a convenience in many ways while at the Exposition. A register will be provided and it is desired that all members visiting the headquarters register their name, local address and probable duration of visit. It is believed that this register will be of much value to visiting members, as well as an indication of the usefulness of a headquarters at an important Exposition.

On Turbo-Dynamos.--II.

(Concluded.)

BY PROF. DR. F. NIETHAMMER.

I HAVE arranged a collection of the formulas for calculating the mechanical strains grst on all important parts of a rotating direct-current armature running with speeds up to 80 to 100 meters per second, which should never be exceeded for economical reasons:

(*a*) The active sheet-iron ring, which is not split in all turbo-dynamos, has to resist a maximum tensile stress from centrifugal forces of $\sigma_e = 0.8 \times 0.082\, v_s^2$ kg. per sq. cm. (v_s = circumferential velocity in meters at the root of the teeth). For $v_s = 80$ meters per second, which is sometimes used, we find $\sigma_e = 400$ kg. per cm².

(*b*) The roots of the teeth are acted upon by a radial tensile strain,

$$\sigma_e{}^1 = \frac{\dfrac{w_t}{g}\dfrac{v^2}{r} + \dfrac{w_w}{g}\dfrac{v^2}{r}}{b_t \,.\, l} \text{ kg. per sq. cm.}$$

w_t = weight of one armature tooth in kg., w_w = weight of the copper of one slot between flanges, $g = 9.81$; v = approx. outside velocity of armature in meters per second, $2r$ = armature diameter in meters, b_t = breadth of a tooth at root in cm., l = axial length of a tooth in cm. The centrifugal force of the windings is supposed to be transmitted to the teeth by wooden or mostly by metallic wedges. For an armature like Fig. 4, with $v = 100$ meters, $\sigma_e{}^1$ comes out 200 kg. per cm².

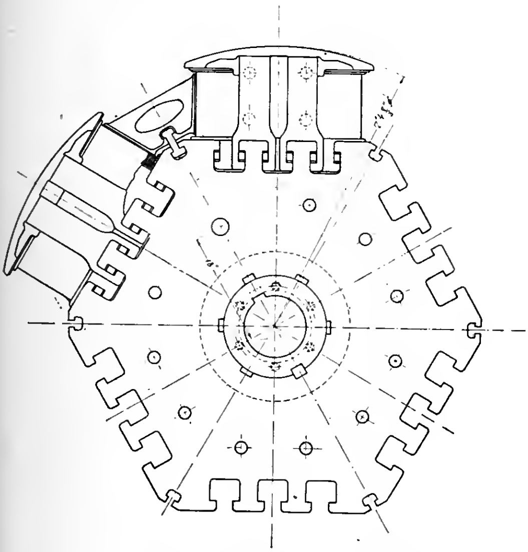

FIG. 6.—UNION COMPANY'S ARMATURE WINDING.

(*c*) The wedges which serve to help the windings of the slots in place are bent by a specific load of bending stress,

$$\sigma_b = 0.8\, \frac{\dfrac{v^2}{r\,g}\, w_w\, b_s}{l\, s^2} \text{ kg. per sq. cm.}$$

b_s = breadth of slot at top (equal to breadth of wedge); s = thickness of wedge; l = length of wedge, all in cm. For a wedge of 5 mm. thickness we find $\sigma_b = 500$ kg. per cm²., which is quite inadmissible for wood.

(*d*) The end connections, which are usually built up as a barrel winding, are usually protected by a seamless (nickel) steel ring (Fig. 4) or specially good bending wire in several layers. This solid or wire ring has to bear a tensile stress of

$$\sigma_e{}'' = 0.082\, v^2 + \frac{w_e}{g}\frac{v^2}{r}\frac{1}{2\pi\, l_r\, s_r} \text{ kg. per sq. cm.}$$

w_e = copper weight of the end connections of one side in kg.; $l_r \times s_r$ = section of ring in sq. cm. For the above example (Fig. 4), with $v = 100$ m. we get $\sigma_e{}'' = 800 + 2{,}000 = 2{,}800$ kg. per cm.², a very high strain. The ring or binding wire ought to be drawn on the winding with a tension equal to $\sigma_e{}''$ in the erecting shop to avoid loosening when running full speed; usually this is not possible in a perfect way.

(*c*) The commutators have to run with speeds up to 50 meters per second. The high centrifugal forces are absorbed by insulated shrinking rings (Fig. 4) put quite close together, or the commutator is composed of a series of very short commutators of usual design. The bending strain of the commutator segments is, in the case of shrinking rings, *a* cm. apart from each other:

$$\sigma_b{}'' = \frac{w_s}{g}\frac{vk^2}{rk}\frac{a}{{}^5/_6\, s\, h^2} = \frac{8\ 9}{1000\, g}\frac{vk^2}{rk}\frac{a^2}{1.3\, h} \text{ kg. per sq. cm.}$$

w_s = weight of one commutator segment in kg. so far as it lies between two shrinking rings; $g = 9.81$; vk = circumferential speed of commutator in meters per second; $2rk$ = commutator diameter in meters; s = mean thickness of a commutator segment in cm.; h = height of commutator segment in cm. For $vk = 50$ m. per second; $rk = 0.15$ m.; $a = 25$ cm.; $s = 0.75$ cm.; $h = 4$ cm., one finds:

$$\sigma_b{}'' = 1{,}500 \text{ kg. per cm}^2.$$

This value is excessively high for copper.

The shrinking rings on the commutators have to withstand the whose centrifugal force of the commutator segments and of their own weight. Their section is determined in the same way as in case *d*. Put G_c = entire commutator copper weight in kg.; l_s = entire axial length of all shrinking rings, together in cm.; s_s = radial height of same in cm.; v = speed of the shrinking rings in meters, then the tensile strain in the rings is

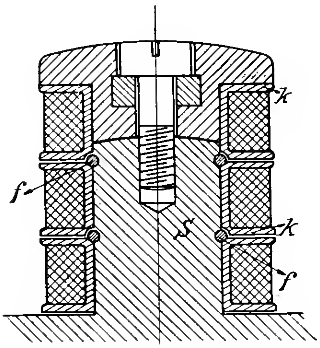

FIG. 7.—SUBDIVIDED COILS.

$$\sigma_e{}'' = 0.082\, v^2 + \frac{G_c}{rk}\frac{0.8}{2\pi\, l_s\, s_s} \text{ kg. per sq. cm.}$$

The rings have to be shrunk on the commutator with a tension at rest equal to $\sigma_e{}''$ to avoid a loose commutator at full speed. In the above example one finds

$$\sigma_e{}'' = 300 + 500 = 800 \text{ kg. per cm}^2.$$

For all the cases mentioned the remark holds good that mostly the strains only depend on the circumferential speed v and not on the diameter of the rotating part.

For three-phases, the rotating field type is nearly universally adopted. The material for the field wheels of high speed consists either of best cast steel or of solid forged iron or of piled thin iron sheets of 0.5 to 3 mm. thickness. The most important part, the field winding, may be (*a*) A *copper strip winding*, the strips *on edge* wound on definite poles; the overhanging parts of the coils must be specially fastened by clamps and angles (Fig. 6, German patent No. 141,295, of the Union Company).

(*b*) A *wire winding* on definite poles, which as a whole is least to be recommended. The coils ought to be subdivided and protected by heavy flanges or spool boxes (Fig. 7); the centrifugal force of each bobbin may be directly transmitted to the pole or pole piece by rings, *f*. (German patent, 134,755). Parsons threads the wires (Fig. 8) through many holes, *c*, in plates riveted or screwed to the

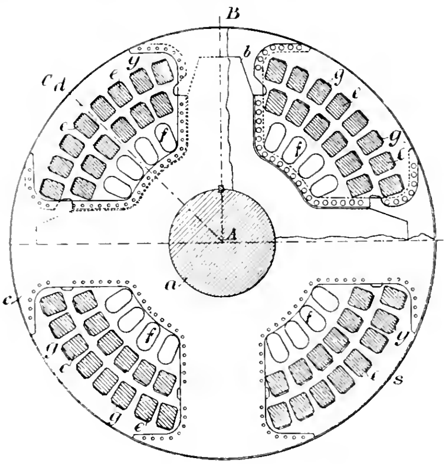

FIG. 8.—PARSONS WINDING.

field star (English patent, 5,907, year 1902), the end connections being fastened by a closed ring.

(*c*) A *definite pole winding distributed in slots* (Fig. 9, German patent, 143,119, of the Westinghouse Company) to divide the effect of the centrifugal forces on the coils; Brown, Boveri & Cie have been using this scheme for some time (German patent, 138,253).

(*d*) *A usual direct-current drum winding* (barrel wave winding), split and connected in such a way that the exciting current may be brought to the winding by two slip rings.

(*e*) A *ring winding* (Fig. 10[2] of the Maschinenfabrik Oerlikon), 1,500 revolutions; exterior field diameter = 860 mm., iron length between flanges = 850 mm.

In every case the exciter voltage has to be kept low, and the section of the exciter winding large, as the number of poles is very small in all turbo-alternators, even of high periodicity, and as it is desirable to have no considerable potential difference between two consecutive turns. The high mechanical pressures on the rotating winding, of 200 kg. per sq. cm. and more, may cause break-downs and leakage currents between adjoining turns, if one does not take special care; the surface of the copper must be absolutely smooth and the insulation layer sufficiently thick and resisting. Ordinarily the exciter voltage is only about 20 to 50 volts.

For some time turbo-alternators were built with rotating armatures and outside field frames (Parsons), the armature slots being perfectly closed and the end connections protected by a closed steel ring. A rotating field winding is, however, much safer to be manufactured than a rotating high-voltage winding and, therefore, the rotating armature has been generally given up. The inductor type of alternator seems to be very tempting for high-speed purposes, as all windings, the induced and inducing ones, are standing still and only

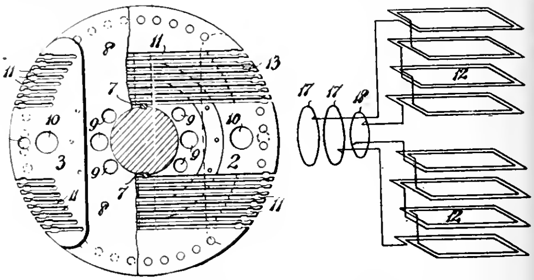

FIG. 9.—WESTINGHOUSE WINDING.

a simple steel wheel is rotating. In this type, however, the stray field losses and the iron losses, especially the eddy currents, are very considerable; the iron losses may even cause excessive heating.

Pole and pole shoes may form one piece with the yoke and hub (Figs. 8 to 10), which is perhaps the safest design. With definite poles usually either pole and pole pieces have together to be attached to the yoke by screws, dove-tails or wedges (Figs. 11 to 14 and Fig. 6), or the pole shoes are fixed in the same way on the pole projections, these being one piece, with the yoke (Figs. 15 to 17). In Fig. 18 (patent of the General Electric Company) sheet-iron bundles are

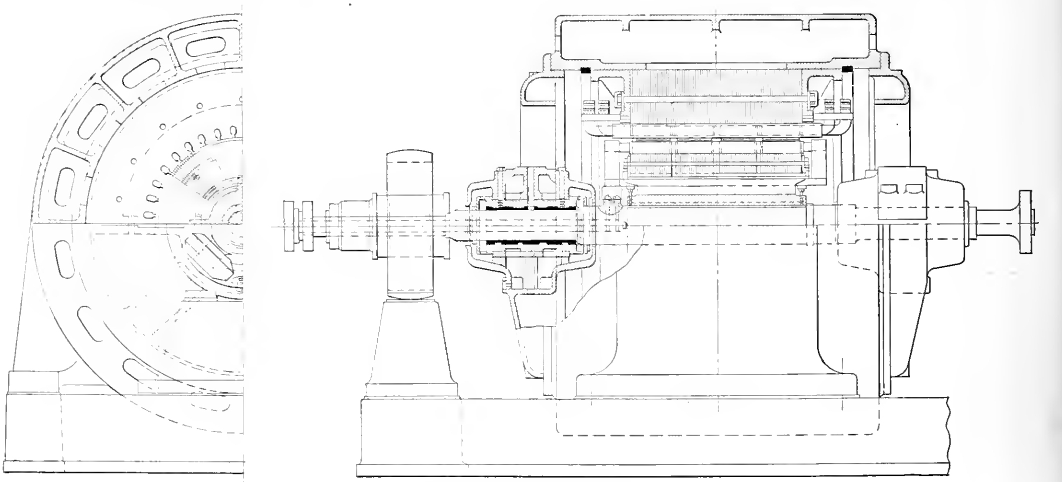

FIG. 10.—OERLIKON RING WINDING.

which for $2p$ poles has to be divided into $2p$ coils connected up alternately in opposite sense. The winding must be composed of very high bars. Fig. 10 represents a case for 1,200 kilovoltamperes and

mortised in the hub by a wedge; the same design is also used for pole pieces.

To get an idea as to the strains in the various devices for attaching pole and pole pieces of high-speed fields, I take the following example from actual practice:

[2] Taken from Strecker; German translation of S. P. Thompson's "Dynamo-electric Machinery."

Four-pole, three-phase, $u = 1{,}500$ revolutions; circumferential speed = 100 meters per second; dimensions, according to Fig. 11; $a = 25$ cm., $b = 4$ cm., $c' = 3$ cm., $h = 30$ cm., axial pole length $l = 30$ cm.; the pole shoes are supposed not to overhang the poles in the axial direction, but on both sides by 5 cm.; copper strips on edge 0.5×5 cm. section, 50 turns per pole; rectangular pole shape.

	Weight	Centrifugal force in kilos
	in Kilos.	
One pole piece	27	45,000
One pole	180	180,000
One coil.	150	150,000

The various means for fixing poles and pole shoes have been chosen as strong as possible with regard to the existing pole section. Fig. 11 diameter d of bolt = 8″; tensile stress

$$= \frac{375{,}000}{20^2 \dfrac{\pi}{4}} = 1{,}200 \text{ kg. per sq. cm.}$$

In Fig. 12 d can hardly be more than 6″, which means a still higher strain. Though these stresses are materially above the usual maximum in screw bolts, of 500 kg. per cm². in most cases, there still will not be sufficient space for the big nuts or screw heads inside the yoke. The tensile strain on two pieces of 3″ screws of Fig. 15 is

$$\frac{195{,}000}{2 \times 1.5^2 \dfrac{\pi}{4}} = 2{,}000 \text{ kg. per cm}^2;$$

in Fig. 16 with $\delta = 6''$,

$$\frac{195{,}000}{15^2 \dfrac{\pi}{4}} = 1{,}100 \text{ kg. per. cm}^2.$$

Only the very best material can effectively withstand these stresses.

The dove-tails of Fig. 13 show with $a = b = 7$ cm. a specific bending stress of

$$\frac{375{,}000 \,.\, a}{2 \times 2 \times \frac{1}{6}\, l\, b^2} = 2{,}700 \text{ kg. per cm}^2.$$

By choosing the angle of the dove-tail equal to 60° instead of 45, the value may be brought down somewhat. The section $c \times l$ (Fig. 13) has to bear a stretching strain of over 1,000 kg. per cm². if $c = 100$ cm. The shearing or transverse strain in the dove-tails is

$$\frac{375{,}000}{2 \,.\, b\, l} = 900 \text{ kg. per cm}^2.,$$

which must be combined in the well-known manner with the bending strain.

By replacing one dove-tail by two (Fig. 14) with $a = b = 3$ cm., the strain just calculated becomes 3,200, 2,100, 1,800 kg. per cm²., and for the pole piece (Fig. 17) with a double dove-tail, 1,600, 1,100, 500 kg. per cm². The specific surface pressures in the dove-tail reach values as high as 1,000 kg. per cm². In the design (Fig. 18) with mortised bundles of 2 x 15 mm. thickness the wedge, F, with a section = 20 x 40 mm. has to withstand bending strains =

$$\frac{375{,}000 \times 1.5}{10 \times 8 \times \frac{1}{6} \times 4 \times 2^2} = 2{,}500 \text{ kg. per sq. cm.}$$

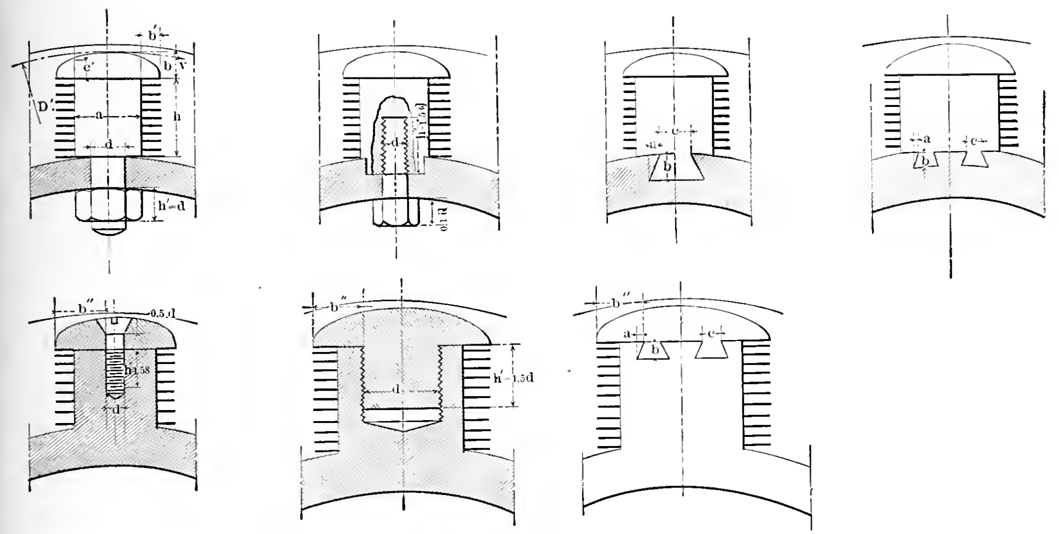
Similar calculations hold good for the design (Fig. 6). Of further importance are the bending pressures in the overhanging parts of pole pieces (Figs. 11 to 14) in the section c':

$$\frac{150{,}000\; b'}{2 \times 2 \times \frac{1}{6}\, l \,.\, c'^2} = 4{,}000 \text{ kg. per sq. cm.}$$

In Figs. 15 to 17 these strains are still higher as b' is to be replaced by the larger value, b'' and 2 in the denominator by 1.5 or 1.

These examples may be sufficient to give an idea of the excessive strains which exist in high-speed field bodies.

4. Finally a few words about noiseless running. It is generally known that all extra high-speed machines have a certain tendency to produce a penetrating, shrill or droning noise, which renders every conversation impossible, and which may be heard over a great distance. The cause is the very rapid air movement, especially the whirls and sudden variations of the section of the streaming air by projecting and overhanging windings or other parts of the generator. Bars insufficiently fixed in the slots or laminated teeth not well



FIGS. 11 TO 17.—VARIOUS METHODS OF COMBINING POLES AND POLE SHOES.

pressed together may magnify the noise considerably. The best remedy consists in designing an absolutely smooth drum or rotating

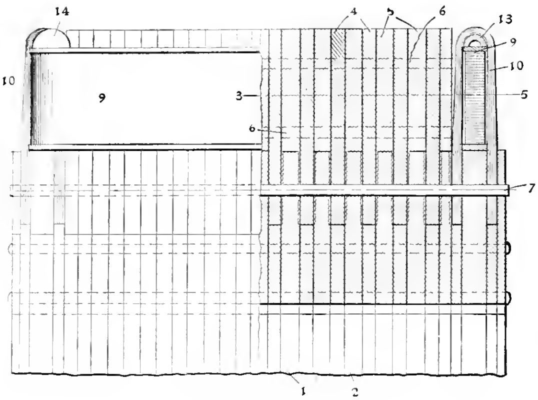


FIG. 18.—GENERAL ELECTRIC METHOD OF COMBINING POLES AND POLE SHOES.

part which can easily be done for the types of Figs. 9 and 10. Definite pole types have to be very often to be entirely closed by cylindrical

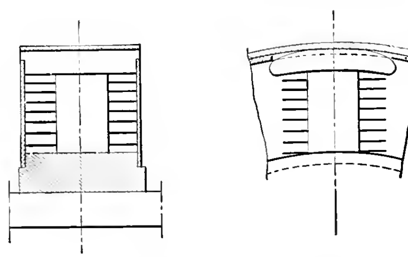

FIG. 19.—COMBINING POLES AND POLE SHOES.

and plain sheets (Figs. 8, 9 and 10), in which suitable air ducts and air holes have to be provided. All windings must be safely fixed by wedges and the teeth must be strengthened by solid end pieces.

New Telephone Company at Indianapolis.

The Indianapolis Telephone Company is the name of a new telephone company organized by the stockholders of the New Telephone Company with a purpose to lease and operate the exchanges and property of the New Telephone Company for a term of 20 years. The company will be incorporated and capitalized at $1,200,000.

The plans for the organization of the Indianapolis Telephone Company and the taking over, leasing and operating of the property of the New Telephone Company are very similar to those under which the Indianapolis Traction & Terminal and the Indiana Union Traction Companies were organized. The dividends on the stock and the interest on the bonds of the New Telephone Company, amounting in the aggregate to $64,000 annually, are guaranteed by the Indianapolis Telephone Company during the entire time of the lease.

The net income of the New Telephone Company last year was $110,000 and there are only 67 stockholders. These figures were given out by the officials for the first time this month. Under the new arrangements the net income will be increased at least $24,000 annually. The Indianapolis Telephone Company will realize $200,000 from stock, the greater part of which will be expended in making extensions so as to accommodate 3,000 more subscribers, 2,000 of whom already have their applications on file. The officers of the New Telephone Company have been elected to fill similar positions in the Indianapolis Telephone Company, viz.: S. P. Sheerin, president; Louis Holwegg, vice-president, and H. B. Sales, secretary and treasurer.

The Letter of Peregrinus on the Magnet, 1269.

THE following translation of this famous letter, to which we made a lengthy reference in our issue of March 11, is from the pen of Brother Arnold, M. Sc., Professor in Manhattan College, New York City. It was addressed by the author from the trenches at Nocera, Southern Italy, in August, 1269, to Sigerus de Foucaucourt, a countryman of his to whom he sought to explain the principle of his magnetic motor.

CHAPTER I.—PURPOSE OF THIS WORK.

DEAREST OF FRIENDS:—At your earnest request, I will now make known to you, in an unpolished narrative, the undoubted though hidden virtue of the lodestone, concerning which philosophers up to the present time give us no information, because it is characteristic of good things to be hidden in darkness until they are brought to light by application to public utility. Out of affection for you, I will write in a simple style about things entirely unknown to the ordinary individual. Nevertheless I will speak only of the manifest properties of the lodestone, because this tract will form part of a work on the construction of philosophical instruments. The disclosing of the hidden properties of this stone is like the art of the sculptor by which he brings figures and seals into existence. Although I may call the matters about which you inquire evident and of inestimable value, they are considered by common folk to be illusions and mere creations of the imagination. But the things that are hidden from the multitude will become clear to astrologers and students of nature and will constitute their delight as they will also be of great help to those that are old and more learned.

CHAPTER II.—QUALIFICATIONS OF THE EXPERIMENTER.

You must know, my dear friend, that whoever wishes to experiment, should be acquainted with the nature of things and should not be ignorant of the motion of the celestial bodies. He must also be skilful in manipulation in order that, by means of this stone, he may produce these marvelous effects. Through his own industry he can, to some extent indeed, correct the errors that a mathematician would inevitably make if he were lacking in dexterity. Besides, in such occult experimentation, great skill is required, for very frequently without it the desired result cannot be obtained, because there are many things in the domain of reason which demand this manual dexterity.

CHAPTER III.—CHARACTERISTICS OF A GOOD LODESTONE.

The lodestone selected must be distinguished by four marks—its color, homogeneity, weight and strength. Its color should be ironlike, pale, slightly bluish or indigo, just as polished iron becomes when exposed to the corroding atmosphere. I have never yet seen a stone of such description which did not produce wonderful effects. Such stones are found most frequently in northern countries, as is attested by sailors who frequent places on the northern seas, notably in Normandy, Flanders and Picardy. This stone should also be of homogeneous material; one having reddish spots and small holes in it should not be chosen; yet a lodestone is hardly ever found entirely free from such blemishes. On account of uniformity in its composition and the compactness of its innermost parts, such a stone is heavy and therefore more valuable. Its strength is known by its vigorous attraction for a large mass of iron; further on I will explain the nature of this attraction. If you chance to see a stone with all these characteristics, secure it if you can.

CHAPTER IV.—HOW TO DISTINGUISH THE PARTS OF A LODESTONE.

I wish to inform you that this stone bears in itself the likeness of the heavens, as I will now clearly demonstrate. There are in the heavens two points more important than all others, because on them, as on pivots, the celestial sphere revolves: these points are called one the arctic or north pole, the other the antarctic or south pole. Similarly you must fully realize that in this stone there are two points styled respectively the north pole and the south pole. If you are very careful, you can discover these two points in a general way. One method for doing so is the following: With an instrument with which crystals and other stones are rounded let a lodestone be made into a globe and then polished. A needle or an elongated piece of iron is then placed on top of the lodestone and a line is drawn in the direction of the needle or iron, thus dividing the stone into two equal parts. The needle is next placed on another part of the stone and a second median line drawn. If desired, this operation may be performed on many different parts, and undoubtedly all these lines will meet in two points just as all meridian or azimuth circles meet in the two opposite poles of the globe. One of these is the north pole, the other the south pole. A proof of this will be found in subsequent chapters of this tract.

A second method for determining these important points is this: Note the place on the above-mentioned spherical lodestone where the point of the needle clings most frequently and most strongly; for this will be one of the poles as discovered by the previous method. In order to determine this point exactly, break off a small piece of the needle or iron so as to obtain a fragment about the length of two fingernails; then put it on the spot which was found to be the pole by the former operation. If the fragment stands perpendicular to the stone, then that is, unquestionably, the pole sought; if not, then move the iron fragment about until it becomes so; mark this point carefully; on the opposite end another point may be found in a similar manner. If all this has been done rightly, and if the stone is homogeneous throughout and a choice specimen, these two points will be diametrically opposite, like the poles of a sphere.

CHAPTER V.—HOW TO DISCOVER THE POLES OF A LODESTONE AND HOW TO TELL WHICH IS NORTH AND WHICH SOUTH.

The poles of a lodestone having been located in a general way, you will determine which is north and which south in the following manner: Take a wooden vessel rounded like a platter or dish, and in it place the stone in such a way that the two poles will be equidistant from the edge of the vessel; then place the dish in another and larger vessel full of water, so that the stone in the first-mentioned dish may be like a sailor in a boat. The second vessel should be of considerable size so that the first may resemble a ship floating in a river or on the sea. I insist upon the larger size of the second vessel in order that the natural tendency of the lodestone may not be impeded by contact of one vessel against the sides of the other. When the stone has been thus placed, it will turn the dish round until the north pole lies in the direction of the north pole of the heavens, and the south pole of the stone points to the south pole of the heavens. Even if the stone be moved a thousand times away from its position, it will return thereto a thousand times as by natural instinct. Since the north and the south parts of the heavens are known, these same points will then be easily recognized in the stone because each part of the lodestone will turn to the corresponding one of the heavens.

CHAPTER VI.—HOW ONE LODESTONE ATTRACTS ANOTHER.

When you have discovered the north and the south pole in your lodestone, mark them both carefully, so that by means of these indentations they may be distinguished whenever necessary. Should you wish to see how one lodestone attracts another, then, with two lodestones selected and prepared as mentioned in the preceding chapter, proceed as follows: Place one in its dish that it may float about as a sailor in a skiff, and let its poles which have already been determined be equidistant from the horizon, i. e., from the edge of the vessel. Taking the other stone in your hand, approach its north pole to the south pole of the lodestone floating in the vessel; the latter will follow the stone in your hand as if longing to cling to it. If, conversely, you bring the south end of the lodestone in your hand towards the north end of the floating lodestone, the same phenomenon will occur; namely, the floating lodestone will follow the one in your hand. Know then that this is the law: the north pole of one lodestone attracts the south pole of another, while the south pole attracts the north. Should you proceed otherwise and bring the north pole of one near the north pole of another, the one you hold in your hand will seem to put the floating one to flight. If the south pole of one is brought near the south pole of another, the same will happen. This is because the north pole of one seeks the south pole of the other, and therefore repels the north pole. A proof of this is that finally the north pole becomes united with the south pole. Likewise if the south pole is stretched out towards the south pole of the floating lodestone, you will observe the latter to be repelled, which does not occur, as said before, when the north pole is extended towards the south. Hence the silliness of certain persons is manifest, who claim that just as scammony attracts jaundice on account of a similarity between them, so one lodestone attracts another even more strongly than it does iron, a fact which they suppose to be false although really true as shown by experiment.

CHAPTER VII.—HOW IRON TOUCHED BY A LODESTONE TURNS TOWARDS THE POLES OF THE WORLD.

It is well known to all who have made the experiment, that when an elongated piece of iron has touched a lodestone and is then fastened to a light block of wood or to a straw and made float on water, one end will turn to the star which has been called the Sailor's star because it is near the pole; the truth is, however, that it does not point to the star but to the pole itself. A proof of this will be furnished in a following chapter. The other end of the iron will point in an opposite direction. But as to which end of the iron will turn towards the north and which to the south, you will observe that that part of the iron which has touched the south pole of the lodestone will point to the north and conversely, that part which had been in contact with the north pole will turn to the south. Though this appears marvelous to the uninitiated, yet it is known with certainty to those who have tried the experiment.

CHAPTER VIII.—HOW A LODESTONE ATTRACTS IRON.

If you wish the stone, according to its natural desire, to attract iron, proceed as follows: Mark the north end of the iron and towards this end approach the south pole of the stone, when it will be found to follow the latter. Or, on the contrary, to the south part of the iron present the north pole of the stone and the latter will attract it without any difficulty. Should you, however, do the opposite, namely, if you bring the north end of the stone towards the north pole of the iron, you will notice the iron turn round until its south pole unites with the north end of the lodestone. The same thing will occur when the south end of the lodestone is brought near the south pole of the iron. Should force be exerted at either pole, so that when the south pole of the iron which had been touched by the north end of the stone is made touch the south end of the stone, or else that part which had been in contact with the south pole is made touch the south pole of the stone, then the virtue in the iron will be easily altered in such a manner that what was before the south end will now become the north and conversely. The cause is that the last impression acts, confounds, or counteracts and alters the force of the original movement.

CHAPTER IX.—WHY THE NORTH POLE OF ONE LODESTONE ATTRACTS THE SOUTH POLE OF ANOTHER AND VICE VERSA.

As already stated, the north pole of one lodestone attracts the south pole of another and conversely; in this case the virtue of the stronger becomes active, whilst that of the weaker becomes obedient or passive. I consider the following to be the cause of this phenomenon: the active agent requires a passive subject, not merely to be joined to it, but also to be united with it, so that the two make but one by nature. In the case of this wonderful lodestone this may be shown in the following manner: Take a lodestone which you may call *A D*, in which *A* is the north pole and *D* the south; cut this stone into two parts, so that you may have two distinct stones; place the stone having the pole *A* so that it may float on water and you will observe that *A* turns towards the north as before; the breaking did not destroy the properties of the parts of the stone, since it is homogeneous; hence it follows that the part of the stone at the point of fracture, which may be marked *B*, must be a south pole; this broken part of which we are now speaking may be called *A B*. The other, which contains *D*, should then be placed so as to float on water, when you will see D point towards the south because it is a south pole; but the other end at the point of fracture, lettered *C*, will be a north pole: this stone may now be named *C D*. If we consider the first stone as the active agent, then the second, or *C D*, will be the passive subject. You will also notice that the ends of the two stones which before their separation were together, after breaking will become one a north pole and the other a south pole. If now these same broken portions are brought near each other, one will attract the other, so that they will again be joined at the points *B* and *C*, where the fracture occurred. Thus, by natural instinct, one single stone will be formed as before. This may be demonstrated fully by cementing the parts together, when the same effects will be produced as before the stone was broken. As you will perceive from this experiment the active agent desires to become one with the passive subject because of the similarity that exists between them. Hence, *C* being a north pole must be brought close to *B* so that the agent and its subject may form one and the same straight line in the order *A B*, *C D* and *B* and *C* being at the same point. In this union, the identity of the extreme parts is retained and preserved just as they were at first; for *A* is the north pole in the entire line as it was in the divided one; so also *D* is the south pole, as it was in the divided passive subject, but *B* and *C* have been made effectually into one. In the same way it happens that if *A* be joined to *D* so as to make the two lines one, in virtue of this union due to attraction in the order *C D A B*, then *A* and *D* will constitute but one point, the identity of the extreme parts will remain unchanged just as they were before being brought together, for *C* is a north pole and *B* a south.

as during their separation. If you proceed in a different fashion, this identity or similarity of parts will not be preserved; for you will perceive that if *C*, a north pole, be joined to *A*, a north pole, contrary to the demonstrated truth, and from these two lines a single one, *B A C D*, is formed, as *D* was a south pole before the parts were united, it is then necessary that the other extremity should be a north pole, and as *B* is a south pole, the identity of the parts of the former similarity is destroyed. If you make *B* the south pole as it was before they united, then *D* must become north though it was south in the original stone; in this way neither the identity nor similarity of parts is preserved. It is becoming that when the two are united into one, they should bear the same likeness as the agent, otherwise nature would be called upon to do what is impossible. The same incongruity would occur if you were to join *B* with *D* so as to make the line *A B C D*, as is plain to any person who reflects a moment. Nature therefore aims at being and also at acting in the best manner possible; it selects the former motion and order rather than the second because the identity is better preserved. From all this it is evident why the north pole attracts the south and conversely, as also why the south pole does not attract the south pole and the north pole does not attract the north.

CHAPTER X.—AN INQUIRY INTO THE CAUSE OF THE NATURAL VIRTUE OF THE LODESTONE.

Certain persons who were but poor investigators of nature held the opinion that the force with which a lodestone draws iron, is found in the mineral veins themselves from which the stone is obtained; whence they claim that the iron turns towards the poles of the earth, only because of the numerous iron mines found there. But such persons are ignorant of the fact that in many different parts of the globe the lodestone is found; from which it would follow that it should turn in different directions according to the locality; but this is contrary to experience. Secondly, these individuals do not seem to know that the places under the poles are uninhabitable because there one-half the year is day and the other half night. Hence it is most silly to imagine that the lodestone should come to us from such places. Since the lodestone points to the south as well as to the north, it is evident from the foregoing chapters that we must conclude that not only from the north pole but also from the south pole rather than from the veins of the mines virtue flows into the poles of the lodestone. This follows from the consideration that wherever a man may be, he finds the stone pointing to the heavens in accordance with the position of the meridian; but all meridians meet at the poles of the world; hence it is manifest that from the poles of the world, the poles of the lodestone receive their virtue. Another necessary consequence of this is that the needle does not point to the pole star, since the meridians do not intersect in that star but in the poles of the earth. In every region, the pole star is always found outside the meridian except twice in each complete revolution of the heavens. From all these considerations, it is clear that the poles of the lodestone derive their virtue from the poles of the heavens. As regards the other parts of the stone, the right conclusion is, that they obtain their virtue from the other parts of the heavens, so that we may infer that not only the poles of the stone receive their virtue and influence from the poles of the world, but also likewise the other parts, or the entire stone from the entire heavens. You may test this in the following manner: A round lodestone on which the poles are marked is placed on two sharp styles as pivots having one pivot under each pole so that the lodestone may easily revolve on these pivots. Having done this, make sure that it is equally balanced and that it turns smoothly on the pivots. Repeat this several times at different hours of the day and always with the utmost care. Then place the stone with its axis in the meridian, the poles resting on the pivots. Let it be moved after the manner of bracelets so that the elevation and depression of the poles may equal the elevation and depression of the poles of the heavens of the place in which you are experimenting. If now the stone be moved according to the motion of the heavens, you will be delighted in having discovered such a wonderful secret; but if not, ascribe the failure to your own lack of skill rather than to a defect in nature. Moreover, in this position I consider the strength of the lodestone to be best preserved. When it is placed differently, i. e., not in the meridian, I think its virtue is weakened or obscured rather than maintained. With such an instrument you will need no timepiece, for by it you can know the ascendant at any hour you please, as well as all other dispositions of the heavens which are sought for by astrologers.

PART II.

CHAPTER I.—THE CONSTRUCTION OF AN INSTRUMENT FOR MEASURING THE AZIMUTH OF THE SUN, THE MOON OR ANY STAR ON THE HORIZON.

Having fully examined all the properties of the lodestone and the phenomena connected therewith, let us now come to those instruments which depend for their operation on the knowledge of those facts. Take a rounded lodestone and after determining its poles in the manner already mentioned, file its two sides so that it becomes elongated at its poles and occupies less space. The lodestone prepared in this wise is then enclosed within two capsules after the fashion of a mirror. Let these capsules be so joined together that they cannot be separated and that water cannot enter; they should be made of light wood and fastened with cement suited to the purpose. Having done this, place them in a large vessel of water on the edges of which the two parts of the world, i. e., the north and south points, have been found and marked. These points may be united by a thread stretched across from north to south. Then float the capsules and place a smooth strip of wood over them in the manner of a diameter. Move the strip until it is equally distant from the meridian-line previously determined and marked by a thread, or

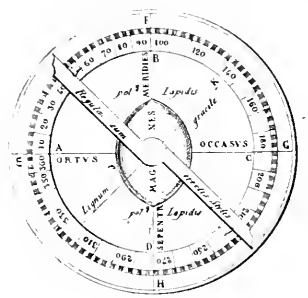

FIG. 1.—AZIMUTH COMPASS OF PEREGRINUS.

else until it coincides therewith. Then mark a line on the capsules according to the position of the strip and this will indicate forever the meridian of that place. Let this line be divided at its middle by another cutting it at right angles which will give the east and west line; thus the four cardinal points will be determined and indicated on the edge of the capsules. Each quarter is to be subdivided into 90 parts, making 360 in the circumference of the capsules. Engrave these divisions on them as usually done on the back of an astrolabe. On the top or edge of the capsules thus marked, place a thin ruler like the pointer on the back of the astrolabe; instead of the sights attach two perpendicular pins, one at each end. If, therefore, you desire to take the azimuth of the sun, place the capsules in water and let them move freely until they come to rest in their proper position. Hold them firmly in one hand, while with the other you move the ruler until the shadow of the pins falls along the length of the ruler; then the end of the ruler which is towards the sun will indicate the azimuth of the sun. Should it be windy, let the capsules be covered with a suitable vessel until they have taken their position north and south. The same method, namely, by sighting, may be followed at night for determining the azimuth of the moon and stars; move the ruler until the ends of the pins are in the same line with the moon or star; the end of the ruler will then indicate the azimuth just as in the case of the sun. By means of the azimuth may then be determined the hour of the day, the ascendant, and all those other things usually determined by the astrolabe. A form of the instrument is shown in the following figure. (See Fig. 1.)

CHAPTER II.—THE CONSTRUCTION OF A BETTER INSTRUMENT FOR THE SAME PURPOSE.

In this chapter I will describe the construction of a better and more efficient instrument. Select a vessel of wood, brass or any solid material you like, circular in shape, moderate in size, shallow but of sufficient width, with a cover of some transparent substance, such as glass or crystal; it would be even better to have both the vessel and the cover transparent. At the center of this vessel fasten a thin axis of brass or silver, having its extremities in the cover above and the vessel below. At the middle of this axis, let there be two apertures at right angles to each other; through one of them pass an iron stylus or needle, through the other a silver or brass needle crossing the iron one at right angles. Divide the cover first into four parts and subdivide these into 90 parts, as was mentioned in describing the former instrument. Mark the parts north, south, east, and west. Add thereto a ruler of transparent material with pins at each end. After this bring either the north or the south pole of a lodestone near the cover so that the needle may be attracted and receive its virtue from the lodestone. Then turn the vessel until the needle stands in the north and south line already marked on the instrument: after which turn the ruler towards the sun if day-time, and towards the moon and stars at night, as described in the preced-

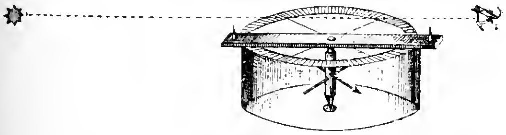

FIG. 2.—PIVOTED COMPASS OF PEREGRINUS.

ing chapter. By means of this instrument you can direct your course towards cities and islands and any other place wherever you may wish to go by land or sea, provided the latitude and longitude of the places are known to you. How iron remains suspended in air by virtue of the lodestone, I will explain in my book on the action of mirrors. Such, then, is the description of an instrument depending on the above-mentioned stone as depicted below. (See Fig. 2.)

CHAPTER III.—THE ART OF MAKING A WHEEL OF PERPETUAL MOTION.

In this chapter I will make known to you the construction of a wheel which in a remarkable manner moves continuously. I have seen many persons vainly busy themselves and even becoming exhausted with much labor in their endeavors to invent such a wheel.

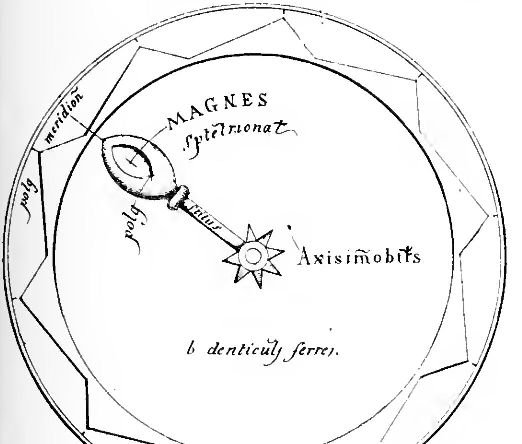

FIG. 3.—THE CONTINUOUSLY-MOVING WHEEL, OR MAGNETIC MOTOR, OF PEREGRINUS.

But these invariably failed to notice that by means of the virtue or power of this stone all difficulty can be overcome. For the construction of such a wheel, take a silver capsule like that of a concave mirror, and worked on the outside with fine carving and perforations, not only for the sake of beauty but also the purpose of diminishing its weight. You should manage also that the eye of the unskilled may not perceive what is cunningly placed inside. Within let there be iron nails or teeth of equal weight fastened to the periphery of the wheel in a slanting direction, close to one another so that their distance apart may not be more than the thickness of a bean or a pea; the wheel itself must be of uniform weight throughout. Fasten the middle of the axis about which the wheel revolves so that the said axis may always remain immovable. Add thereto a silver bar and at its extremity affix a lodestone placed between two capsules and prepared in the following way: When it has been rounded and its poles marked as said before, let it be shaped like an egg; leaving the poles untouched, file down the intervening parts so that thus flattened and occupying less space, it may not touch the sides of the capsules when the wheel revolves. Thus prepared, let it be affixed to the silver rod just as a precious stone is placed in a ring; let the north pole be then turned towards the teeth or cogs of the wheel somewhat slantingly so that the virtue of the stone may not flow diametrically into the iron teeth but at a certain angle; consequently when one of the teeth comes near the north pole and owing to the impetus of the wheel passes it, it then approaches the south pole from which it is rather driven away than attracted, as is evident from the law given in a preceding chapter. Therefore such a tooth would be constantly attracted and constantly repelled. In order that the wheel may do its work more speedily, place within the box a small rounded weight made of brass or silver of such a size that it may be caught between each pair of teeth; consequently as the movement of the wheel is continuous in one direction, so the fall of the weight will be continuous in the other. Being caught between the teeth of a wheel which is continuously revolving, it seeks the center of the earth in virtue of its own weight, thereby aiding the motion of the teeth and preventing them from coming to rest in a direct line with the lodestone. Let the places between the teeth be suitably hollowed out so that they may easily catch the body in its fall, as shown in the diagram below. (See Fig. 3.)

Farewell: finished in camp at the siege of Lucera on the eighth day of August, Anno Domini MCCLXIX.*

Telegrams and Cables in War.

The following reply, inspired by the Foreign Office, to Japan's rejoinder to the Russian protest against the violation of Corean neutrality, has been issued in St. Petersburg and is apparently intended to be accepted as official:

Japan's argument that she was justified in landing troops in Corea before the declaration of war because she had Corea's permission, and also that these troops arrived in Corea after "the existence of a state of war," is without value, as Corea in January promulgated her neutrality to the Powers, which received it warmly, Great Britain even officially conveying expressions of gratitude to the Corean Government. Therefore, no state of war gave the Japanese the right to violate her neutrality by landing troops in her territory. Even the consent of Corea, though extorted by the Japanese, is without force, from the fact that the dispatch of troops was not only before the war, but before the breaking off of diplomatic relations, as clearly established and indeed acknowledged by the Japanese themselves.

Japan's contention in defence of the attack on the Russian ships at Chemulpo, that the port was not neutral on February 9, is false, again because Corea had proclaimed her neutrality. Japan's denial of malicious interference with the transmission of Russian telegrams over the Danish cable cannot be sustained. A telegram to Baron de Rosen (then Russian minister to Japan), at Tokio, sent from St. Petersburg February 4, was not delivered till the morning of February 7. That delay did not occur on the Siberian line, as was shown by the fact that a reply to a telegram from Viceroy Alexieff sent at the same time was received the same day. Therefore, it is conclusive that the De Rosen telegram was held by the Japanese and not delivered for two days.

Communication with M. Pavloff (then Russian minister to Corea) by the Corean telegraph ceased in the middle of January. As the Coreans were enjoying friendly relations with Russia, there is good ground for believing that the interruption was due to the Japanese. Thereafter M. Pavloff used a mail steamer or a special warship to communicate with Port Arthur. The minister of Russia at Seoul February 8, therefore, knew nothing of the diplomatic rupture.

Japan pleads that the charge against her seizure of Russian merchantmen before the declaration of war cannot lie after the establishment of prize courts. Their seizure before the declaration of war being piracy is not defensible by the establishment of prize courts, which cannot exist before a declaration of war. The steamer *Russia* was seized in the waters of southern Corea even before M. Kurino had presented his note here.

The reply concludes: "Our information regarding Japan's announcement that in future Corea would be under her administration came from M. Pavloff and also from the representative of a friendly power at Seoul. Japan's denial, consequently, is fruitless, as also is

*This farewell sentence is in most MSS., but is not in Gasser's printed edition of the letter, 1558.

the attempt to refute our statement that the Russian minister and consul at Seoul were told to leave. We had conclusive proof in St. Petersburg on February 10 that the French minister at Seoul had officially notified our representatives that the Japanese Government had intimated that they should leave, and that the Japanese had occupied territory in Corea. M. Pavloff was unable to notify our consul at Fusan, his telegram being refused at the telegraph office."

A Metrical Detector for Electric Waves.

By L. Heathcote Walter, M. A.

THE want of a satisfactory metrical detector of electrical oscillations has so often been pointed out that a description of the new oscillation galvanometer, which I have designed in conjunction with Prof. J. A. Ewing, F.R.S., will probably be of interest.

This instrument differs from any of the detectors hitherto invented, in that the oscillations directly and visibly indicate their presence by a mechanical movement proportional to their intensity, as a galvanometer responds to a continuous current, and in that such

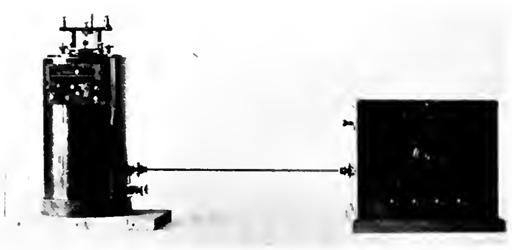

FIG. 1.—WAVE DETECTOR COMPLETE.

quantitative readings can be directly obtained over a practically unlimited range without any alteration to the aerial wires or other conducting masses used to pick up the waves.

Prof. Fessenden some time ago pointed out the impossibility of obtaining a direct mechanical movement from the oscillations, owing to their extremely high frequency. By using an extraneous source (a rotating field) to supply the energy, and making use of the novel property which I discovered—that by passing such oscillations along a magnetic wire, itself subjected to a rotating magnetic field, the hysteresis is enormously *increased,* the effect of the oscillations being to permit more of this externally supplied energy to be utilized—this difficulty is overcome, the same effect being obtained, and to a vastly increased extent, as if the direct electro-dynamic effects of the oscillations were made use of. The instrument depends, as before stated, upon the increase of hysteresis (in the sense of work done per reversal) produced in a bobbin of steel wire, placed in a rotating field,

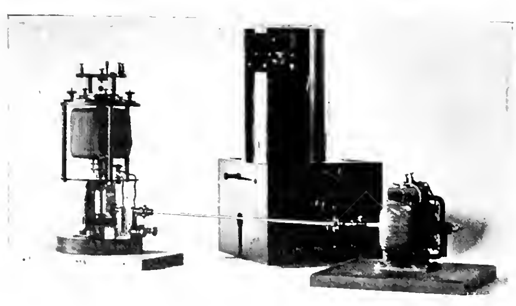

FIG. 2.—DETECTOR WITH COVERS REMOVED.

when oscillations are passed through the wire itself, such oscillations producing an oscillatory circular magnetism superimposed on the varying longitudinal magnetization. The principle and the preliminary experiments leading up to the design of the present instrument are described in a paper by Dr. Ewing and myself on "A New Method of Detecting Electrical Oscillations," read before the Royal Society, London, England, on February 11, 1904.

Briefly, the instrument is an adaptation of the Ewing hysteresis tester, in this case the specimen being held fast and the magnetic field revolving, being driven by an electric motor. The bobbin, which is supported on pivots in jewels, is prevented from following the field by means of a controlling spring. The winding on the bobbin is made as nearly non-inductive as possible by being double-wound, and consists of a number of turns of very fine insulated steel wire, the plane of the turns being at right angles to the axis of the bobbin. The bobbin is immersed in petroleum or thicker mineral oil, according to the amount of damping required, the oil also serving to steady the deflection and to improve the insulation. The instrument has to be considered from two standpoints, the requirements of which are somewhat different. Thus for physical measurements and metrical purposes generally, the instrument is provided with a permanent magnet system for the field, and readings are taken by spot and scale, a mirror being fixed on the bobbin axis. When the apparatus is working there is a steady deflection due to the normal hysteresis, and the spot can be set with the zero at any part of the scale. On oscillations arriving, the bobbin gives a throw in the same direction as that due to the normal hysteresis (same direction as the field), returning to the normal position as soon as the oscillations cease.

The sensibility of the instrument can be made anything desired, firstly, by suitable proportions being given to the bobbin and the wire winding. Thus for measurements near a spark coil, a very small bobbin and short length of wire of larger diameter and lower resistance will suffice, and such wire can be more highly insulated. For other purposes where a low resistance may be desirable, the instrument can be equipped with a bobbin provided with a copper primary of low resistance, either on the bobbin itself or as a fixture external to it, through which the oscillations are to pass, acting inductively on the magnetic winding, which in such a case must be inductively wound and closed on itself; several modifications of such windings are shown in the specification of United States Patent No. 741,570, so that it is unnecessary to describe them. An instrument provided with a bobbin of the highest sensibility can, however, be

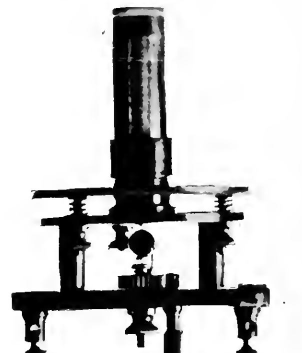

FIG. 3.—VIEW OF THE BOBBIN IN ITS CELL.

used for such measurements if a shunt circuit is employed, and in such a case a sensibility of the order of an average coherer is attainable.

For a receiver for wireless telegraphy, the requirements are somewhat different; sensitiveness (within limits) and rapidity of action being the dominating requirements. Any type of recording apparatus can be actuated by means of the bobbin, a syphon recording attachment having been so employed with good results. That is, however, merely a case of mechanical adaptation, such a possibility being self-evident. The oscillations used for this purpose are also of much greater wave length, necessitating, in the case of simple direct excitation connection (for the best results) the use of a more considerable length of wire on the bobbin. When using a transformer or a shunt connection the conditions are different. I hope shortly to be able to publish the results of experiments in this connection. The figures show one type of the instrument in which an electromagnet furnishes the revolving field. In Fig. 1 the complete instrument is seen. In Fig. 2 the outer covers are removed, to show the magnet system and the interior of the motor box. Fig. 3 shows the bobbin in its cell.

Calculation of the Equivalent Ampere-Turns of Windings for Single and Polyphase Currents.—III.

(Concluded.)

BY C. F. GUILBERT.

NEXT let us examine the case when u is an odd number. As is shown in Figs. 9 and 10, the law of distribution of the m.m.f. is then the same for all the poles. It is to be seen that as in the analogous case of separate phase windings, the coil having a width equal to the pole step a, should be considered for each pole as having half the number of turns as the others; that is to say, $\frac{N}{2u}$ instead of $\frac{N}{u}$. The peripheral widths, b, of the successive and concentric coils are thus:

$$a, \quad \frac{a}{\pi}\left(\pi - 2\frac{2\pi}{qu}\right), \quad \frac{a}{\pi}\left(\pi - 2\frac{4\pi}{qu}\right), \quad \ldots \frac{a}{\pi}\left(\pi - 2(u-1)\frac{\pi}{qu}\right)$$

which correspond for the quantity, $\frac{b}{a}\frac{\pi}{2}$, to the values

$$\frac{\pi}{2}, \quad \frac{\pi}{2} - \frac{2\pi}{qu}, \quad \frac{\pi}{2} - 2\frac{2\pi}{qu}, \ldots \frac{\pi}{2} - \frac{u-1}{2}\frac{2\pi}{qu}$$

The total m.m.f. per pole of the phase considered is then, taking account of the remark made with respect to the first coil.

$$\mathfrak{F}_t' = \frac{4}{\pi^2}\frac{NI\sqrt{2}}{2u}\left[1 + 2\left(\cos\frac{2\pi}{qu} + \cos 2\frac{2\pi}{qu} + \ldots + \cos\frac{u-1}{2}\frac{2\pi}{qu}\right)\right]$$

This expression is analogous to that which has already been obtained above for the case of separate phases; the number of turns is the same and the only difference consists in that the ratio of the progression of the arcs is double: that is to say, $\frac{2\pi}{qu}$ instead of $\frac{\pi}{qu}$. The desired result may then be obtained simply by replacing in the expression found above, q by $\frac{q}{2}$, in such a manner as to double the ratio. The expression for $\mathfrak{F}$ is then, for q phases,

$$\mathfrak{F}_t' = q\frac{2}{\pi^2}\frac{\sin\frac{\pi}{q}}{u\sin\frac{\pi}{qu}}$$

Unlike in the case of separate phase windings, the formula for calculating the equivalent m.m.f. is different for an even and odd number of slots per pole and per phase. This, however, is the only divergence.

As has been done in the case when u is even, it is interesting to compare this formula with that which corresponds to the case where the phases are not superposed. The two formulas differ only by the two quantities:

$$\frac{\sin\frac{\pi}{2q}}{u\sin\frac{\pi}{2qu}} \quad \text{and} \quad \frac{\sin\frac{\pi}{q}}{u\sin\frac{\pi}{qu}},$$

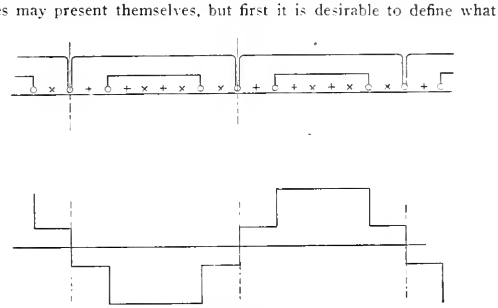
which reduce for large values of u to

$$\frac{2q}{\pi}\sin\frac{\pi}{2q} \quad \text{and} \quad \frac{q}{\pi}\sin\frac{\pi}{q}.$$

For the case of three-phase windings the values of these quantities are, for the factor $\frac{3}{\pi}$, 1 and 0.866, which leads to a difference identical to that corresponding to the case where u is even.

M.M.F. OF SUPERPOSED PHASE WINDING WITH COMMON SLOTS.

We finally come to the case where each slot contains the conductors of the two phases in equal number. As previously, several cases may present themselves, but first it is desirable to define what

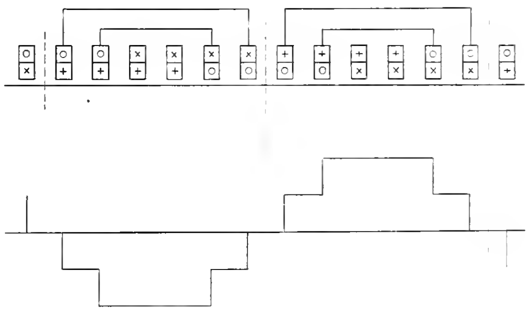


FIGS. 9 AND 10.

should be understood by u in order to obtain formulas comparable to those already established.

We will designate this time by $2u$, the number of slots per pole containing conductors of the same phase, so that the actual distance of two slots referred to the case of a bipolar machine will remain $\frac{\pi}{qu}$, u thus representing here the half number of slots corresponding per pole to a single phase. It is evident that since the number of slots, $2u$ per pole per phase, is always even whether u is odd or even, we can always form per pole a certain number of coils having the same number of turns. Thus one formula can be established for all values of u.

Take, for example, the case where u is even. It will be seen by Figs. 11 and 12 that we can form for each pole identical coils, giving rise consequently to the same law of distribution for all the poles.



FIGS. 11 AND 12.

The widths b of elementary coils have for value.

$$\frac{a}{\pi}\left(\pi - \frac{\pi}{q u}\right),\ \frac{a}{\pi}\left(\pi - 3\,\frac{\pi}{q u}\right)\ \ldots\ldots\ \frac{a}{\pi}\left(\pi - (2u-1)\,\frac{\pi}{q u}\right)$$

Applying the formula giving the m.m.f. of a single coil, bearing in mind that the number of turns for each elementary coil is here $\frac{N}{2u}$, if N is always the number of conductors per pole per phase, we will have in making summation for all the coils of the same phase,

$$\mathfrak{F}_i = \frac{4}{\pi^2}\,\frac{NI\sqrt{2}}{2u}\left[\cos\frac{\pi}{2qu} + \cos\frac{3\pi}{2qu} + \ldots\ \cos(2u-1)\frac{\pi}{2qu}\right]$$

This expression is identical with that obtained for the case of superposed windings having the same number of slots per pole, but where each slot contains only the conductors of a single phase. The expression for the equivalent m.m.f. of the entire windings will then again be

$$\mathfrak{F}_i = q\,\frac{2}{\pi^2}\,\frac{\sin\frac{\pi}{q}}{2u\sin\frac{\pi}{2qu}}\,NI\sqrt{2}.$$

This formula thus applies to all cases where the phases are superposed except for an odd number of slots per pole. In this latter case alone the distribution of the instantaneous m.m.f. is not the same at two neighboring poles.

In what precedes we have taken for granted that each pole comprises an entire number of slots; or in other words, that the total number of slots is a multiple of the number of poles. This is true only for looped or series-parallel windings having a number of circuits in parallel equal to or a multiple of the number of poles. Consequently, the formulas are not rigorously exact in the case of alternators and asynchronous motors as usually wound. However, since an exact calculation would lead to expressions too complicated for practical use, the two general formulas deduced can be adapted for separate phase windings and superposed windings by leaving aside the case of an odd number of slots per pole and per phase. It suffices for this purpose to transform them by introducing the total number of slots of the machine, $u_1 = 2pqu$, $2p$ being the number of poles and b the total number of conductors per phase, $N_1 + 2pN$. The expression for the equivalent m.m.f. of windings by distinct phases thus becomes

$$\mathfrak{F}_i = q\,\frac{2}{\pi^2}\,\frac{\sin\frac{\pi}{2q}}{2qpu\sin\frac{p\pi}{2qpu}}\,2qpNI\sqrt{2}$$

$$= \frac{1}{\pi^2}\,q^2\,\frac{\sin\frac{\pi}{2q}}{u_1\sin\frac{p\pi}{u_1}}\,N_1 I\sqrt{2}$$

and that for the equivalent m.m.f. of the superposed phase winding becomes

$$\mathfrak{F}_i = q\,\frac{2}{\pi^2}\,\frac{\sin\frac{\pi}{q}}{2qpu\sin\frac{p\pi}{2qpu}}\,qpNI\sqrt{2}$$

$$= \frac{2}{n^2}\,q^2\,\frac{\sin\frac{\pi}{q}}{u_1\sin\frac{q\pi}{u_1}}\,N_1 I\sqrt{2}.$$

The formulas which give the equivalent ampere-turns per pole of a polyphase winding traversed by alternating currents with an effective value, I, can be combined in a single formula,

$$\mathfrak{F}_i = \frac{q}{2}\,KNI\sqrt{2}.$$

in assuming with Prof. Blondel that $K = \left(\frac{2}{\pi}\right)^2 k$,

where k can take the following values:

$$k = \frac{\sin\frac{\pi}{2q}}{u\sin\frac{\pi}{2qu}}.\quad \text{Separate phase winding;}$$

$$k = \frac{\sin\frac{\pi}{q}}{2u\sin\frac{\pi}{2qu}}\quad \text{Superposed phase winding, } u \text{ even;}$$

$$k = \frac{\sin\frac{\pi}{q}}{u\sin\frac{\pi}{2qu}}.\quad \text{Superposed phase winding, } u \text{ odd;}$$

It is only to be remarked that the factors k are none other than the reduction factors of the induced e.m.f. permitting account to be taken of the distribution of the conductors of the same phase in several slots per pole.

Together with the exact formulas preceding we can finally employ the following approximate formula in the case where the number of slots corresponding to each pole is not a whole number:

$$\mathfrak{F}_i = \frac{q}{2}\left(\frac{2}{\pi}\right)^2 k\,N_1 I\sqrt{2},$$

when k can have the values

$$k = \frac{q\sin\frac{\pi}{2q}}{u_1\sin\frac{p\pi}{u_1}}.\quad \text{Separate phase winding;}$$

$$k = \frac{q\sin\frac{\pi}{q}}{2u_1\sin\frac{p\pi}{u_1}}.\quad \text{Superposed phase winding.}$$

These formulas naturally contain the preceding except that corresponding to the case where u is odd and the winding is of the superposed phase type. They are very convenient for application in all cases and may be found of much service in the calculation of alternators and asynchronous motors.

The Telephone Substation.—I.

By ARTHUR V. ABBOTT, C. E.

INDUCTION COILS AND SUB-STATION CIRCUITS.

THE earliest telephone line was simplicity itself. As illustrated in Fig. 1, it consisted of two magneto-telephones, each of which acted as transmitter and receiver alternately, united by a pair of wires, or even one wire could be dispensed with, and the "ground" employed as a return, as shown by the dotted line. But such a cir-

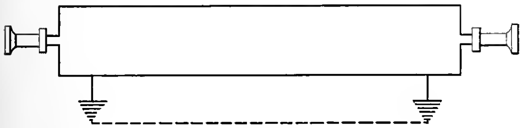


FIG. 1.—EARLIEST TELEPHONE CIRCUIT.

cuit could be employed only over short distances, because the impulses of the magneto telephone are too feeble to be intelligible over long lines. The invention of the battery telephone, which acted as an electric valve to allow power from a source independent of the transmitter to be available, rendered it practical to talk over much longer lines; but with this improvement simplicity had to be sacrificed. It was necessary to provide a separate receiver and transmitter at each station, and introduce a battery as a source of electricity, something as shown in Fig. 2. Consider such a circuit in the light of the transmitter operating as an electric valve. The effect on the receivers will be approximately proportional to the *changes* in the currents that traverse the circuit, and not at all to the actual volume of electricity. These pulsations are produced solely by such variations in the total opposition offered to the flow of electricity from the battery, as are due to the increase and decrease in the resistance of the microphonic contact in the transmitter set up by the changes in pressure on its diaphragm caused by the sound waves that impinge thereon. A circuit of this kind may be divided into four parts, each of which presents its own individual barrier to the passage of electricity: First, there is the opposition due to the receiver. The ohmic resistance of the receiver may vary from 50 to 100 ohms; but as its coils are wound upon an iron core, its reactance is large, and, at the high frequency of telephonic currents, its impedance is considerable. Second, there is the opposition offered by the line wire, which will vary with its length, material and size. Assuming the line to be essentially straight, and of average length, say, about a mile, its opposition will be chiefly due to ohmic resistance, because its inductance is inappreciable, only a few millihenrys and the entire impedance of this portion of the circuit will not exceed, say, 100 ohms. Third, there is the opposition of the battery that is entirely non-inductive, and, even in the case of high resistance cells, will not

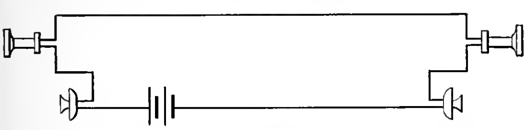

FIG. 2.—CIRCUIT WITH BATTERY TRANSMITTER WITHOUT INDUCTION COIL.

exceed a dozen ohms. Finally, there is the variable, though non-inductive, resistance of two transmitters, either of which may, from time to time, change from a fraction of an ohm to several hundred ohms, though it is rare to find transmitter resistance of more than 25 or 30 ohms.

So a telephone line connected as shown in Fig. 2 will offer an impedance of a thousand ohms or more, though its ohmic resistance would rarely rise above two hundred. Now, to make a favorable assumption, suppose the transmitter to be endowed with an ability to produce a maximum variation of 50 ohms; it would then be able to change the total impedance of the circuit about 5 per cent., and, therefore, its power of producing pulsations in the line current will be correspondingly small. To enable a transmitter to produce a greater effect, the circuit must be so planned that the change in the transmitter resistance will be a much greater proportion of the total circuit impedence. This Mr. Edison accomplished in 1878 by the aid of a *transformer,* or, in telephonic language, an induction coil. Mr. Edison's arrangement, and one which still survives unchanged in local battery installations, is shown in Fig. 3. Two receivers (*RR*) are united by a line, at each sub-station a transformer (*C*) is introduced. This transformer consists of an iron core upon which there are two windings, one of coarse wire, having relatively few turns, and of low resistance, while the other is of fine wire, much higher resistance and many more turns. The fine wire is placed in series with the line and receivers, while the coarse wire forms a local circuit, having a transmitter and battery in series with it. Fifteen years ago the theory and use of the transformer was but little known and practised, the spark coils of Ruhmkorff and others being about the only application of the principles of induction. While Prof. Gray had previously employed an induction coil in telegraphic work, Edison's application of it to the battery transmitter must be regarded as one of the great inventions of telephony.

The induction coil performs four entirely separate and distinct functions: First, it provides a local circuit for each transmitter, that by proper design can be made of so low an impedance that the variations in the resistance of the microphonic contact shall form a very large percentage of the total electrical opposition of the circuit. Second, it removes both transmitters from the line circuit, thus decreasing its resistance. Moreover, as the transmitter is of variable resistance, its direct presence in the talking circuit is exceedingly

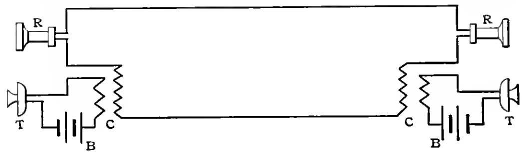

FIG. 3.—CIRCUIT WITH INDUCTION COIL.

objectionable. Third, the analogy of the transmitter to the electric valve leads to the belief that all the impulses it produces are positive quantities, or, so to speak, the transmitter injects jets of electricity into the line. Its action may be illustrated by Fig. 4, in which *AB* is the line of no current, *CD* the current line when the transmitter is at rest, and *EF* a representation of positive impulses superimposed upon the line *AB*. Even under the most favorable conditions, the impulses produced by the transmitter are small in comparison with electrical quantities that are met with under other circumstances. A few measurements upon transmitter currents have been made, the most recent of which are the experiments by Prof. Cross at the Massachusetts Institute of Technology. The various vowel sounds were pronounced in as uniform a tone as possible in front of various transmitters and the result on line current measured by a dynamometer. These tests are summarized in Table No. 1:

TABLE I.

LINE CURRENTS FROM VARIOUS TRANSMITTERS WITH DIFFERENT VOWEL SOUNDS.

Kind of Transmitter.	Vowel Sounds and Currents in Milliamperes.			
	a	o	u	i
Hunning	.737	.787	.503	.213
Fitch	.450	.548	.442	.264
Blake	.123	.144	.114	....
Edison	.088	.123	.144	.072
Magneto	.123	.260	.238	.103

Subsequently, other tests were made with a solid back, to test the effect upon the line current of varying pitch of the voice an octave. These results are shown in Table No. 2:

TABLE II.

RELATION OF LINE CURRENT TO PITCH OF SOUND.

Vibrations per second.	Vowel Sounds and Current in Milliamperes.				
	a	e	i	o	u
128	.300	.270	.250	.350	.200
236	.670	.620	.420	.680	.540

Fourth, the addition of the transformer changes radically the form of the impulses, because a pulsating current impressed upon the primary gives rise to a wave in the secondary which is an alternating one, and is more efficient in exciting the diaphragm of the receiver. This is illustrated in Fig. 5, in which *AB* is the line of no current, corresponding to *AB* of Fig. 4, while *CD* represents the current wave in the secondary, corresponding to *EF* in the primary. Fifth, it is well known that one of the most valuable properties of the transformer is its ability to vary the current and pressure relations of its primary and secondary circuits. This variation is nearly in proportion to the ratio of the number of turns in the primary to the number of turns in the secondary. Thus, if there are P turns in the

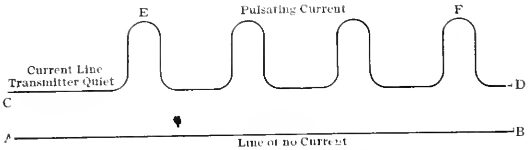

FIG. 4.—DIAGRAM OF CURRENT IN A TRANSMITTER CIRCUIT.

primary and P' turns in the secondary, the ratio is $\frac{P'}{P}$. If V volts be applied to the primary producing in the secondary a current of C am-

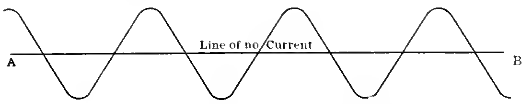

FIG. 5.—CURRENT IN SECONDARY OF INDUCTION COIL.

peres, the volts at the terminal of the secondary will be $\frac{V P'}{P}$ and the current will be $\frac{C P}{P'}$. Now, line losses in any transmission system are proportional to the square of the current which is employed, while the energy transmitted is proportional to the product of the pressure

and the current. Consequently, by reducing the current and increasing the pressure, the same amount of energy may be transmitted, accompanied by much less loss. Owing to arcing at the michrophonic contacts it is impossible to operate a transmitter excepting at low voltages; but the induction coil affords the ability to transform the low pressure and relatively large current of the local circuit into high pressure and correspondingly small current in the secondary circuit.

Enough has been said to indicate the importance of the induction coil, and, therefore, the desirability of obtaining such a design as

will secure a maximum of the advantages thus outlined. Unfortunately, records of experiments made to determine the best proportions for induction coils are few and difficult to secure. A valuable set of experiments upon a number of coils made by the Swiss Telephone Department is reported by Sir William H. Preece. The results of these experiments are summarized in Table No. 3:

The tests referred to in Table No. 3 were made by taking the induction coil of a Blake transmitter as a standard and comparing therewith, over various lengths of lines, the coils designated in the first column of the table. Unfortunately, the electrical properties of the standard coil were not recorded.

The Iowa Electrical Association Convention.

The fourth annual convention of the Iowa Electrical Association will be held at Des Moines on April 13 and 14, 1904, at the Savery House. The programme as announced so far is as follows: "Uniform Accounting," by Austin Burt; "Electric Motors," by George W. Carson; "Combustion of Iowa Fuel," by Prof. George W. Bissell; "Incandescent Lamp Tests," by Prof. Spinney; "Station Steam Piping," by Mr. Gartlain; "Nernst Lamp Experiences," by Mr. G. C. Gardner; "Series Street Lighting," by Mr. Harrison; "Multiple Street Lighting," by Mr. Lee; "Storage Batteries," by Mr. Reavy; "Demonstrated Talk on Station Accounting," by Mr. Robert Ferris; "Question Box," by W. J. Greene.

Methods of Signaling and Operating in Telephone Exchanges—VI.

By Kempster B. Miller and Charles S. Winston.

(Concluded.)

WESTERN ELECTRIC SYSTEM C. MODERN BELL SYSTEM.

In the previous article descriptions were given and illustrated of the two Western Electric toll systems, designating them as A and B. In one two wires are used in toll trunk circuits, in toll systems. In the other three wires are used in the toll trunk circuits. As neither of these systems, A or B, was considered entirely satisfactory by the American Bell Telephone Company, particularly on the ground of not being rapid enough in operation, the engineers of this company set to work to design a system capable of more rapid service, and which would have the advantages of both systems, A and B, with as few as possible of their disadvantages. As a result, about two years ago there was put in operation a new system, which has apparently proved more satisfactory than any of the systems yet tried by the Bell Companies, although it has one disadvantage in the extreme complexity of some of its circuits.

In this system, which we will call "System C," the cord circuits at the toll board are of such a nature that they can be used without change for making connections between two toll stations or between one toll and one local station. The system has advantages in that it affords greater ease of operation and, further, in that the cord circuit is not encumbered by a repeating coil and a repeating coil key. Toll trunk circuits are furnished, appearing as jacks in the toll sections and as plugs and lamps at the toll switching positions on the local switchboard. In addition to this recording toll trunk circuits are provided, which end at the recording operator's positions in lamps and jacks, and appear as multiple jacks only in each section of the local multiple switchboard. Locking relays and lamps controlled by them are used in both the toll line and cord circuits in place of line and clearing-out drops. At each subscriber's operator's position at the multiple switchboard, there is furnished one or more pairs of "tone test" cords adapted to throw a special tone busy test on to any line. With one of these cords which is intended to be connected with the jacks of the local common battery subscribers, is associated a white lamp, and with the other, which is used to connect with the jacks of the recording toll trunks, a red lamp.

The method of operation of this system in establishing a local to toll connection is as follows, reference being made to Fig. 12. A local subscriber desiring to talk over a long distance line will signal his local operator and ask for "toll" or "long distance." The operator will then insert the answering plug of a pair of tone test cords into the multiple jack of the calling line. She will then withdraw the answering plug of the regular pair of cords which she inserted into the answering jack of the calling subscriber's line in response to his call. The white lamp in the tone test cord circuit will remain unlighted as the subscriber with whose line the jack is connected has his receiver off its hook. With the second plug of the tone test circuit the operator will then test the multiple jacks of the recording toll trunk lines, and upon finding one that is not in use, will insert the plug into it. The second (red lamp) in the tone test circuit will also remain unlighted, but a lamp at the recording operator's position associated with the recording trunk circuit will light, and the recording operator having plugged into this jack will find out from the calling subscriber what toll connection is desired and also the number of his own line. From this information the recording operator will make out a ticket.

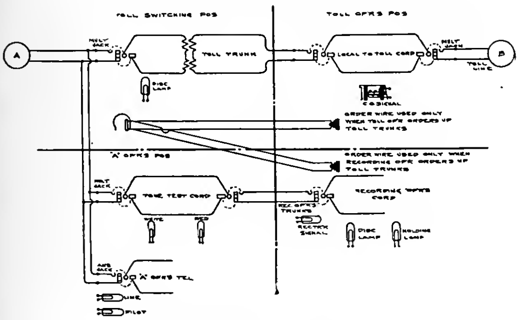

FIG. 12.—SHOWING CONNECTION OF LOCAL TO TOLL SUBSCRIBERS. WESTERN ELECTRIC "C."

Generally, the recording operator is furnished with cord circuits each having a single plug and two lamps. One of these lamps (the holding lamp) is placed under the control of the calling subscriber when the plug with which it is associated is inserted in the proper toll trunk jack, and the second is a disconnect lamp. The operation of the latter lamp will be described below.

It will be seen that the method by which the recording toll operator receives the information from a calling subscriber is the same as that used in the Kellogg system, with the exception that the connection between the calling subscriber's line and the recording toll trunk is made by means of special pair of cords instead of by regular cords, as in the Kellogg system, and also through the multiple jack of the calling subscriber's line, rather than through his answering jack.

After making out the ticket the recording operator has two courses of action open to her, her decision depending on whether or not she has reason to believe the connection called for may be at once obtained. If she thinks it will be some time before it will be possible to establish the connection desired, she will tell the calling subscriber to hang up his receiver and wait until called. The hanging up of the subscriber's receiver will light the white lamp of the tone test cord used in making the connection, but the subscriber's operator will pay no attention to this, her signal for taking down the connection being the lighting of the red lamp. Having told the calling subscriber to hang up his receiver, the recording operator will then pass the ticket to the toll line operator and remove her plug from the recording toll trunk jack, which will light the red lamp in the tone test cord circuit at the multiple switchboard. The lighting of this red lamp gives the signal to the subscriber's operator to take down the connection, and she therefore pulls down both of the tone test plugs leaving the calling subscriber's line free for other use.

The object of the white lamp in the tone test cords is not to serve as a disconnect lamp, but to provide at all times a signal by means of which the local subscriber can attract the attention of the operator even while his line is being held for the toll connection.

If, after making out the ticket, the recording operator has reason to believe that the connection may be at once obtained, she will press an order-wire key enabling her to speak directly to the toll switching operator at the multiple switchboard and give her the number of the line with which the connection is to be made. In response to this the toll switching operator will give the recording operator the number of the trunk line which is to be used, and the recording operator will place this number on the ticket. The toll switching operator will then test the multiple jack of this line, and will receive the special "busy" test, due to the presence of the tone test plug in the multiple jack at the section at which the call was initiated. She is instructed, however, to disregard this special busy test, but to all other operators in the exchange this test has the same significance as the regular "busy" test.

After the toll switching operator has inserted the designated trunk plug into the multiple jack of the calling line, the recording operator will withdraw her plug from the recording trunk jack and insert it into a multiple jack of the toll trunk line designated. These trunks are multipled on all toll and recording sections. After speaking to the subscriber, thus satisfying herself that the connection is, so far, complete, and that the subscriber has given his proper number, she will tell him to "wait a minute." She will then pass the ticket to the toll operator who has charge of the toll line with which the connection is to be established. The act of withdrawing the recording plug from the recording trunk jack will light the red lamp in the tone test circuit at the multiple board, and the operator will remove the tone test plugs from both the subscriber's and recording trunk multiple jacks. It will then be impossible for the subscriber to signal his operator, but the act of moving his receiver will flash the holding lamp at the recording operator's position. As, previous to removing the tone test cords at the multiple switchboard, the white lamp in this circuit was under the control of the subscriber, it will be seen that there is no time that the subscriber cannot signal the exchange.

It will be seen that if the recording operator thinks it will require some time to obtain the toll line desired, she causes the local subscriber's line to be freed, and leaves the toll operator to order up the toll trunk. If, however, she believes that the connection can be immediately made up, she causes the local subscriber's line to be held as busy, and will order up the toll trunk herself. In the former case the ticket received by the toll operator will have no trunk line designated upon it, while in the latter case, it will.

When, therefore, the toll line operator receives the ticket from the recording operator, she will, if no trunk is designated, first insert an answering plug into the multiple jack of the desired toll line and ring. After the call has been answered, the toll operator will give to the switching operator over an order wire, the number of the subscriber's line with which connection is to be made, and receive in return the number of the trunk line to be used, whereupon she will insert the calling plug, which is associated with the answering plug in use, into the multiple jack of the designated trunk line and call the desired subscriber by ringing. If she finds that the trunk line is designated on the ticket and that the recording operator has already ordered up the connection at the toll switching section, she will first insert an answering plug into the jack of the trunk designated on the toll ticket. This act will light the disconnect lamp in the cord circuit of the recording operator, and this operator will remove the plug from the toll trunk jack. The supervision of the connection will then be entirely in charge of the toll line operator, as the multiple board subscriber will light the supervisory lamp in the toll cord circuit by operating his receiver hook. Having inserted the answering plug into the jack of the toll trunk line designated, she will test the multiple jack of the toll line. If, by testing, the toll line operator finds that the desired toll line is not in use, she will insert the calling plug of the pair used, into the multiple jack of this line and call up the toll subscriber. She will listen in at short intervals so as to know when the subscriber answers and the conversation has begun.

At the end of conversation the act on the part of the toll subscriber or of a distant operator of sending current over the line, or on the part of the common battery subscriber of hanging up his receiver, will operate the relay in the toll cord circuit and light the supervisory lamp. The operator will then throw the listening key, thus extinguishing the lamp, and, after having assured herself that the signal is for disconnection, take down the plugs. When she withdraws the plug from the toll trunk circuit, she will automatically light the disconnect lamp associated with this trunk line at the toll-switching position of the multiple switchboard, and the toll-switching operator will remove the toll trunk plug from the multiple jack of the subscriber's line.

The toll trunk line leading from the toll board to the toll-switching operator's position of a local multiple board consists of two wires only, and in order to bring about the advantage of having the cord circuits on the toll positions universally adaptable to any kind of a connection, the repeating coils are placed in the toll trunk circuits rather than in the toll cord circuits. In spite of the presence of this repeating coil, however, the toll operator, in this system, rings the local subscriber instead of having the trunk operator perform this operation, as in system A. This arrangement is made possible by a series of relays so wired that when the toll operator rings on the trunk line, the generator current which she thus causes to flow over the trunk line and through one side of the repeating coil at the toll-switching end of this line, will pull up a relay which will send generator current out on the subscriber's line without passing through the other side of this repeating coil.

When a person at a long distance station desires to converse with a common battery subscriber the current from his generator will energize a relay which will light a lamp at the toll board. From this it will be seen that the latest Bell practice discards the old scheme of having drops for line signals on the toll boards, as well as for supervisory, lamps being used in their places.

When the toll operator answers a call the act of inserting the plug into the answering jack will extinguish the line lamp. Having found that the call is for a common battery subscriber, the toll operator will speak over an order wire to the toll-switching operator at the multiple board telling her the number of the common battery line with which the connection is to be made and the toll-switching operator will designate the trunk, and, after testing and finding that the line is clear, insert the plug of this trunk into the multiple jack of the local line. The toll operator will insert the calling plug associated with the answering jack in use into the multiple jack of the toll trunk line and ring the local subscriber. At the end of the conversation the disconnect signals will be received in the same manner as described, the signal coming to the toll operator, who, when she takes down the connection, conveys the disconnect signal to the toll-switching operator.

If in a call from a toll for a local subscriber the call-switching operator in testing the multiple of the designated local line, as described, finds it busy, she will insert this plug into a busy back jack, and thus notify the toll operator by tone that the connection cannot be put up immediately. The toll operator will then tell the person at the toll station, who is making the call, to hang up his receiver and that as soon as possible he will be called.

Meanwhile the toll operator will frequently remind the toll-switching operator to test the multiple jack of the local subscriber's line in order to ascertain when it is no longer busy, so that the connection may be made.

It would seem that this latter feature might be improved upon, and that a signal should be provided for notifying the toll operator automatically as soon as the local subscriber's line was no longer busy, after which she could immediately complete the connection.

For the handling of toll-to-toll calls, a separate position or positions is provided on the toll board called "through" positions. If the toll operator receives a call from a toll line for another toll line she will make out a ticket for it in the same manner as if the call were for a local line and, on completing the ticket, will establish the connection herself if the line called for is not busy. If, however, it is in use, she will pass the ticket to the through operator, who has in front of her a multiple jack of each line, and, in some exchanges, a lamp which remains lighted as long as that line is busy. This operator, as soon as she finds that both lines are free, either by noting that the lamps of both lines are extinguished, if her position is provided with lamps, or by testing, in case she has none, will establish the connection. At the end of the conversation on such a connection the supervisory lamp will light in the ordinary manner when either of the toll subscribers turns his generator crank.

Recent Electrochemical Developments.

ELECTROMETALLURGY OF STEEL.

Among the successful European metallurgists who have introduced electric furnace methods into the metallurgy of iron and steel is Mr. C. A. Keller, of Paris, whose steel process is in use at Kerrousse, in the Houille·Blanche ("white coal") district. It has recently been stated that Messrs. Keller, Leleux & Co. are contemplating a steel works in this country. For this reason a patent granted on March 15 to Mr. C. A. Keller is of special interest. He uses a double furnace, the upper furnace operating as a stack furnace for the reduction of the metal, while the lower furnace serves for refining or alloying purposes. The upper furnace is characterized by the continuity of its operation and the possibility of the utilization of great power and great capacity. It contains four vertical electrodes disposed upon the four corners of a square, their lower extremities being placed in the refractory vessel which constitutes the fusion chamber. The column of ore charged into the furnace may serve at the same time for a chimney with return flue, and has an exterior diameter such that it may be located between the upper extremities of the electrodes which emerge above the roof of the fusion chamber. Two electrodes are connected to the positive pole and the other two electrodes to the negative pole of the supply circuit. With this arrangement the operation of the furnace is rendered continuous, since one of the four electrodes may be easily replaced without stopping the operation. Readings of the four ammeters, in the branch circuit of each electrode, permit adjusting the intensity of the current in the four heating zones. Each of the electrodes is provided with an operating mechanism which permits its vertical regulation.

IRON-NICKEL STORAGE BATTERY.

Two patents granted to Mr. Thomas A. Edison refer to details of mechanical construction of his iron-nickel storage battery. One patent relates to the use of glass tubes or rods for mechanically supporting and separating the electrodes, and at the same time for electrically insulating the electrodes from the bottom and sides of the containing vessel. The other patent relates to a light, cheap tray, arranged to carry and securely hold together a series of storage batteries, so that, by assembling several such trays with their cells, a complete outfit is produced which is particularly adapted for use on automobiles.

Vertical Motor-Generator Set.

A short time ago the Lend-Gastein (Austria) branch of the Neuhausen Aluminum Industrie Gesellschaft was equipped completely with electrical apparatus furnished by the Oerlikon Company, of Oerlikon, near Zurich, Switzerland. The most interesting feature of this installation is the use of vertical motor-generator sets, of which there are six in all. This type was chosen owing to the satisfactory service given by the vertical generators used in connection with the turbines in this plant. It was found that the vertical arrangement permitted the machinery to be handled with greater ease. The carbon and copper dust falls directly downward and, therefore, cannot get into the armature windings.

The motors of each set are of the synchronous type, each built to give 1,000 hp at 10,000 volts, 45 cycles, 340 r.p.m. The 160-volt, direct-current generators are each of 560-kw capacity.

The generator field is made of cast iron. The motor armature is placed directly above the field of the generator, and is enclosed by a single-piece cast-iron frame. The rotors of both machines are rapidly attached to each other and revolve around the stationary shaft, which is lubricated by means of the oil cup shown at the top of the shaft in Fig. 3. The total weight of the rotors is 27,500 pounds. This weight is taken up by a spur foundation located beneath the commutator of the generator. The stationary cast-steel spur plate is frustum-shaped and rests in a cast-iron pan. The shell of the lower foundation, which is built into the commutator, has a flange at its bottom resting on the spur plate. Both the spur plate and flange have a circular groove for taking up the oil after lubrication. This oil is pumped through the machinery under a pressure of ten atmospheres. The entire supporting foundation, including the pumping machinery, is built in a cast-iron housing completely filled with oil so that lubrication is insured even if the pump fails. The oil is kept cool by a spiral copper pipe which conveys cold water through it.

The generators have twelve poles each and are shunt wound. The armature has an outside diameter of 4.9 ft. and a core diameter of 1.3 ft. The core is cooled by two ventilating slits. The armature contains 204 open slots for the windings, each slot containing four insulated copper wires. The connection between the armature winding and the commutator is made according to a new system devised by the Oerlikon Company, consisting in the use of copper forks, each of which combines two commutator laminations, separated from each other by twice the polar division, with the corresponding armature winding. The commutator consists of 408 segments of hard-drawn copper, 24 in. long, and with an outside diameter of 36 in. All insulating rings in the interior of the commutator are of mica. The twelve poles which carry the shunt windings are built of soft sheet iron and are screwed to the field frame. Corresponding to the twelve poles the brush holder has twelve brushes, each of which is furnished with 11 carbon tips. These brushes are arranged so that all of them can be raised simultaneously when necessary to clean or true the commutator.

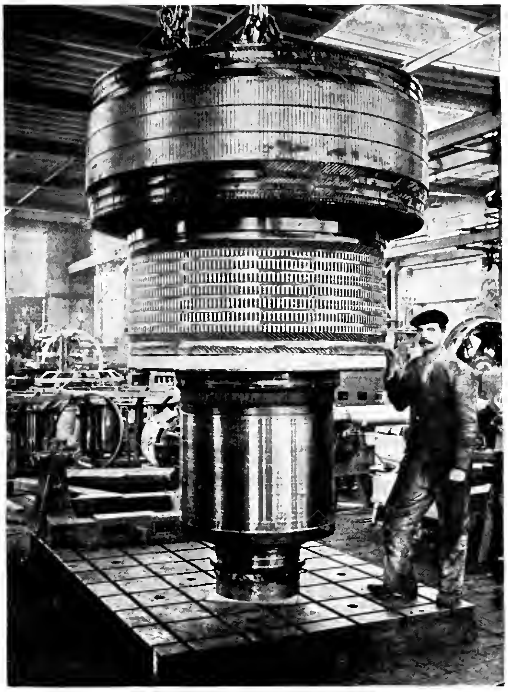

FIG. 2.—VIEW OF THE ROTORS.

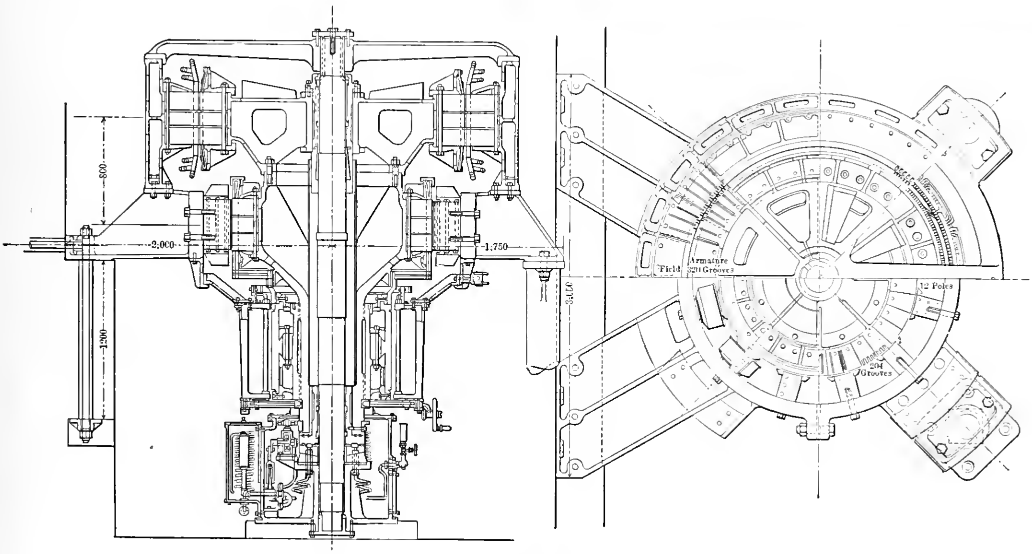

FIG. 1.—DETAILS OF VERTICAL MOTOR-GENERATOR SET.

The motor has sixteen poles. The high-tension winding is laid in 192 slots. Each slot contains eighteen series wires insulated from each other by mica sheets .1 in. thick. The winding is hand-wound, and the wires have a diameter of 4 mm. The rotor of the motor has

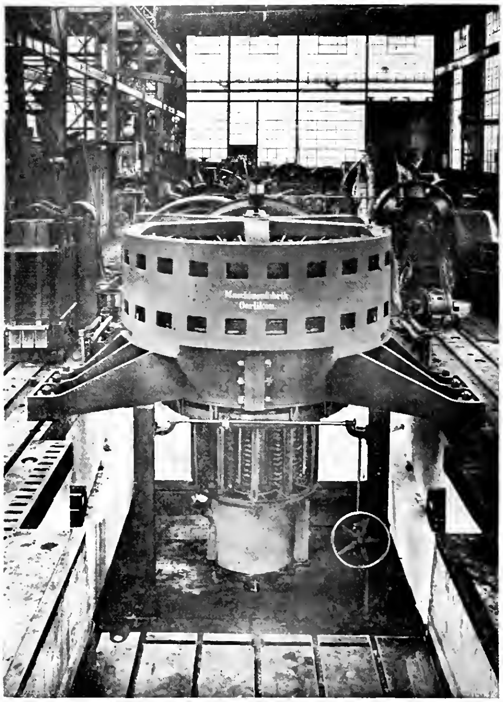

FIG. 3.—GENERAL VIEW OF MACHINE.

a short-circuited winding laid in 320 semi-open slots. Each slot contains two spool halves. Each spool forms a closed winding, and consists of three parallel copper strips 8 x 2.5 mm. cross-section. It is noteworthy that the motors have an air-gap of 2.5 mm., though *cos ϕ* attains a maximum of 0.94.

Drying Out High-Tension Transformers.

To the March issue of the *Electrical Club Journal* Mr. J. S. Peck contributes an article on "Methods of Drying out High-Tension Transformers." Three methods are described, namely, by the use of internal heat, external heat and internal and external heat combined. In applying the first-mentioned method, the transformer should be placed, if possible, in its case, though this is not essential, as it may be left in its shipping case or even placed on the floor of a dry room. If dried out in a case the cover should be removed to give free circulation of air. The low-tension winding should be short-circuited, and a sufficient voltage impressed on the high-tension winding to circulate the desired current through the coils. For large transformers (250 to 500 kw), approximately one-fifth normal full-load current will be sufficient to raise and maintain the coils at the desired temperature, viz.: approximately 90° C. (194° F.). For small transformers a somewhat larger current will be required. For circulating this current through the windings, from 1 per cent. to 2 per cent. of the normal high-tension voltage at normal frequency will be required; thus, for a 10,000-volt transformer from 100 to 200 volts is necessary. For controlling the current a rheostat may be placed in series with the high-tension winding.

In applying the external heat method, the transformer should be placed in a wooden box, the packing case answering the purpose very well. An opening should be made near the bottom and another at the top of the box to permit a circulation of air and also to serve as a means of controlling the temperature of the air inside the box. The heat may be applied by circulating current through resistances, the iron grid form is frequently most suitable, placed at the bottom of the box. It should be applied at such a rate that the transformer coils will be maintained at approximately 90° C. (194° F.). Care should be taken to protect the transformer from direct radiation from the heaters. Care must also be taken to see that there is no inflammable material near the heaters which may catch fire. This method of drying out has an advantage over the method outlined in (*a*) in that direct current may be used for heating.

Instead of placing the heater inside the box containing the transformer, it may be placed outside and the heat carried into the box through a suitable pipe. Where this plan is used the heat may be generated by the direct combustion of gas, coal or wood, but none of the products of combustion should be allowed to enter the box containing the transformer. Heating by direct combustion is not advised except in case where electric current is not available.

In the internal and external heat methods the transformer should be placed in a wooden box as in the above method, and external heat applied, while at the same time a small amount of current is circulated through the transformer windings. The method of circulating the current should be the same as given in the first method discussed, and the method of applying the external heat the same as given in the second method. The current should, of course, be considerably less than when no external heat is used, the value being determined, to a certain extent, by the amount of external heat applied. This method is used occasionally where direct current only is available, a certain amount of current being passed through the high-tension winding only, as the low-tension winding is ordinarily wound for so heavy a current that it cannot be obtained economically from a direct-current circuit.

The length of time the drying-out should be continued will depend largely upon the condition in which the transformer is received, and unless in very bad shape, a week's run should be sufficient to put the transformer in good condition. In certain cases, however, it has been found necessary to continue the run for a somewhat longer time.

It will be found that when the current is first applied and the transformer heats up, the insulation resistance will drop very rapidly, until the desired temperature is reached; then, as this temperature is maintained constant, the resistance will gradually increase. It will also be found that variations from a constant temperature will cause wide changes in resistance. Resistance readings should be made every few hours and the drying continued until the resistance no longer increases, or increases at a very slow rate.

Certain precautions are to be observed in the work. In order to dry out the transformer, it is necessary to maintain it at a temperature which approaches the point where fibrous materials deteriorate. Great care must, therefore, be observed during the whole period of drying out to see that the temperature does not reach a value much in excess of 90° C.

For measuring the temperature of the transformer coils, several thermometers should be used. These should be placed well in between the coils, near the top of the transformer, and screened from air currents, so that they will indicate the maximum temperature of the windings. As the temperature will rise quite rapidly at first, it is necessary to watch the thermometers carefully to see that the maximum allowable temperature is not exceeded.

As the transformer is soaked with oil, on account of the test which it receives in the works, the material is in an inflammable condition, and while hot it may be ignited very easily by a very small arc, or from a blaze of any kind. Before beginning the drying out, it is well to have some chemical extinguisher, or at least a supply of sand, at hand, which may be used in case of necessity. In general, it is not safe to attempt the drying out of transformers unless constant attention can be given to them.

Wireless Telegraphy in the Navy.

The United States Navy Department at Washington has recently made arrangements for the trial of several wireless telegraph systems between the Brooklyn Navy Yard and the station at Navesink Highlands, N. J. The system which produces the best result later will be tested between shore stations and ships and between ship and ship. The Navy Department continues to receive encouraging reports of wireless telegraphic achievements at sea.

New Telephone Patents.

RECEIVER HOLDER.

One has only to see a receiver dangling upon the end of its cord, representing the condition of holding the line while leaving the telephone, to wonder why some auxiliary support for the receiver is not provided. H. L. Goodwin, of Kansas City, has thought that such an auxiliary should be provided and he has put his thoughts into definite form in a receiver holder for which he has obtained a patent. This holder is bent up out of wire having a U-shaped form at one end into which the receiver may be slipped. The other end is given various shapes, according to the type of telephone instrument upon which it is to clamp. Clamping for all types results, however, from the natural spring of the wire. The only objection that can be advanced against such a support is that a receiver left upon it in error, resulting in the "hold-up" of the line, is much more likely to attract attention when swinging about at the end of a cord than when placed upon a support.

ANTISEPTIC MOUTHPIECE.

A new development in the antiseptic mouthpiece line is a joint invention of Messrs. W. M. English and A. H. Ten Broeck, of San Francisco, recently patented. This consists of a metal bell piece from one side of which an antiseptic-containing receptacle projects. The wall of the bell piece contains many fine perforations leading into the receptacle. Access to the receptacle for the insertion of antiseptic may be made in any one of various evident ways, for example, by making the bottom removable.

REPEATING APPARATUS.

S. Kitsee, of Philadelphia, has produced a most odd-looking repeater. It consists essentially of a galvanometer, the motions of whose needle is mechanically transferred to a pair of microphonic contacts. The galvanometer coil is, of course, included in the incoming circuit, and we are told that its resistance must be adjusted to suit the particular line in use. The needle of the galvanometer is compound, consisting of three independent needles upon the same spindle, their magnetic axes varying in direction by approximately 15°. The spindle is mounted in jeweled bearings. It carries not only the needles, but a long, horizontal arm, each end of which is bent downward. These ends carry conducting points which dip into small vessels containing dilute sulphuric acid. The variation of resistance of the primary of the repeating circuit results from the variation of the distance in the acid between the conducting point of the moving arm and a contact point in the bottom of the vessel. It would certainly seem impossible to proportion such an apparatus that the moving system might come anywhere near synchronizing with complex rapidly changing voice currents.

ANTISEPTIC MOUTHPIECES.

Things seem to be running in pairs in this patent issue and it is therefore not surprising to find two patents for antiseptic mouthpieces. One of these describes an apparatus commonplace enough, being merely a special form of perforated metallic mouthpiece lining with a space for antiseptic cotton or similar material between it and the mouthpiece proper. This is the combined invention of W. M. English and A. H. Ten Broeck, of San Francisco.

The second is entirely different, being built on the barbed-wire fence principle in that the ordinary mouthpiece is provided with a crown of round-headed pins so distributed that one cannot get his lips in contact with the transmitter. Its utility is certainly questionable from at least two points of view. In the first place, good transmission demands that the lips approach the mouthpiece closely, and secondly the metal crown should apparently be almost as good a receptacle of infection as such part of the hard rubber mouthpiece as one is liable to bring his lips in contact with. Mr. J. Blum, of Baltimore, has patented this latter device.

Plan to Merge Long-Distance Telephone Lines in Central States.

An important meeting was held at Indianapolis, Ind., on March 19 and attended by a number of the most prominent telephone men in the Central States. The purpose of the meeting was to formulate plans and discuss means of effecting a consolidation of all independent long-distance telephone companies operating in Western Pennsylvania, Ohio, Indiana, Illinois, Kentucky and Missouri, thus forming a chain of lines from Philadelphia, Cleveland, Indianapolis to Louisville and St. Louis. The United States Long-Distance Telephone Company, over whose lines the traffic of numerous independent telephone companies is now carried on, is said to be backing the enterprise, although the idea was originally conceived by S. P. Sheerin, of Indianapolis. In addition to the above named company the following are interested in the merger: The Pittsburg and Allegheny Telephone Company, the Cuyahoga Telephone Company, of Cleveland; the Citizens' Telephone Company, of Columbus, Ohio; the New Long-Distance Telephone Company of Indiana; the newly organized Indianapolis Telephone Company; the United Telephone Company of Bluffton, Ind. (covering the oil belt), and the Kinloch Telephone Company, of St. Louis. It is understood that an arrangement was agreed upon between the various companies represented whereby they will use each other's line for long-distance service in other States, and that where necessary short connecting lines will be built, so that coöperative service may be put into effect. The following prominent telephone men attended the meeting: J. C. Splain, of Pittsburg; Max Reber, J. B. Hoge and F. S. Dickson, of Cleveland; James E. Brailey, Jr., of Toledo; C. M. Foster, C. H. Ledlie, Breckinridge Jones, W. D. Orthwein, W. F. Nolker, Philip Stock, J. I. Drummond, Philip Scanlon, H. L. Reber, W. H. Bassett, E. B. Denison, W. R. McCanne and W. D. Pitman, of St. Louis; J. D. Powers, J. A. Armstrong, M. R. Telu and M. Brailey, of Louisville; Hugh Dougherty, of Bluffton, Ind.; C. S. Ramsey, of Crawfordsville, Ind.; S. P. Sheerin, H. B. Sales and H. B. Gates, of Indianapolis. After the meeting the officials of the New Long-Distance Telephone Company, of Indianapolis, gave an elaborate dinner to the visitors, at the Columbia Club.

Electricity Versus Steam.

A discussion as to the relative merits of steam and electricity took place recently at Public School No. 5, New York City, when it was voted that steam was now in second place. The case for electricity was brilliantly and cogently presented by Master Gainer, whose clinching arguments we quote from the daily papers, as follows:

"Electricity is better than steam, for gas hurts the eyes, and then besides, the coal trust is against steam. Steamships can be propelled by electric motors, without smoke, so can trains, as was showed by the race the other day in the papers, when an electric car beat the Empire State Express. If there was not sich a thing as steam there wouldn't a been that awful cave-in down town, when 25 live men were killed. There's lots of other sich things I could quote if they was time. Electricity cures people that are nervous and sick people, too, and there is electric fans in all theatres in summer. What does steam do but boil?"

CURRENT NEWS AND NOTES.

HIGH-TENSION MEETING IN CHICAGO.—The Chicago branch of the American Institute of Electrical Engineers will hold its meeting for the discussion of high-tension transmission on March 29 at 1741 Monadnock Block at 8 P.M., as usual.

WIRELESS TELEGRAPHY IN THE WAR.—One of the Port Arthur dispatches says: "The wireless telegraph station opposite the light house has failed to work, its instruments having been disturbed by currents sent out by the Japanese ships equipped with the wireless system."

QUICK CABLING.—A remarkable piece of quick cabling was done a few days ago between Melbourne, Australia, and London, England, a distance of some 17,000 miles. The result of a cricket match was transmitted by the British Pacific Cable, Canadian Pacific Telegraphs and the Commercial Atlantic Cable in two and one-half minutes. This is without doubt a record time. The message was relayed nine times.

MAGNETIC CLUB DINNER.—A complimentary dinner will be given by the Magnetic Club, of New York, to the officials of the New York Telephone Company and the New York & New Jersey Telephone Company. The dinner will be held about April 21 and a large attendance of telephone men is expected. The idea of this dinner is to afford an opportunity for telephone and telegraph men to meet and become better acquainted with one another.

IMPROVEMENTS IN DELIVERY OF TELEGRAMS.—The Postal Telegraph-Cable Company has adopted a new form of message blank and delivery envelope. The envelope is of the kind having an opening, technically called a "window," cut out of the front surface, a transparent oiled paper filling the space. The message blank is so folded that the address thereon will come in front of the "window" when the message is enclosed in the envelope. This innovation obviates the liability of error in rewriting the address on the envelope in the old way, and saves much time in handling. The Postal Company has always been quick to adopt new ideas tending to facilitate the handling of its business.

GERMAN TROLLEYS.—Mr. F. H. Mason, United States Consul-General at Berlin, writes: "Most, though not all, of the city lines are the property of one incorporated company, the Grosse Berliner Strassenbahn-Gesellschaft, which carried last year the imposing contingent of 316,000,000 passengers, an increase of 18,000,000 over the traffic of the previous year. For this service it received as fares 28,903,833 marks ($6,879,722), an average—including commutation and all other tickets—of 2.17 cents per fare. Within the city limits of Berlin the uniform fare for any distance is 10 pfennigs (2.5 cents), but there are no transfer tickets and the same fare must be paid on each line traversed by the passenger. Tickets from the central portions of the city to the outlying suburbs cost 2.5, 4 and 5 cents, according to distance, but all these are subject to slight reductions for commutation tickets. The importance of the Grosse Berliner as a factor in the transportation system of the city may be inferred from the fact that out of a total city and suburban population of 2,500,000 souls its lines carry an average of 865,000 passengers per day. The electric elevated and underground railway carried 29,473,355 passengers, for which the company received as fares 3,557,785 marks ($46,752), or an average of 3 cents for each person. The heaviest traffic of the year was during the month of December, when 2,870,653 persons were carried; next came March, with 2,700,000; and last, July, with 2,093,000 passengers."

LETTERS TO THE EDITORS.

What Constitutes Invention.

To the Editors of Electrical World and Engineer:

SIRS:—I am interested in your editorial in the issue of March 19 on invention vs. engineering development. No one regrets more than patent lawyers the issue of unnecessary and trivial letters patent for invention; nevertheless I think your editorial is somewhat severe on the Patent Office, and on those who apply for what they regard as inventions.

The federal judges have always declined to define in advance what is invention, saying that each case must stand upon its own circumstances. You will doubtless pardon my saying that *ex cathedra* definition is no more to be looked for from an editor of a technical journal than from the courts; and I venture to say that it will be no more successful as a test, if made. It should be borne in mind that from 50 to 60 per cent. of the letters patent litigated are declared invalid for one reason or another: this certainly seems "drastic" enough without recommending that the courts go into legislation. They are sufficiently inclined that way now to suit most lawyers.

An intesesting side light is thrown on your editorial by the next but one on "High Tension Insulation," as follows:

"At pressures of 50,000 volts * * * * * * the insulation of the transformer leads becomes a problem even tougher than the insulation of the line * * * * * * . Of insulating compounds having good mechanical properties and able to withstand moderate voltages, there are many; but when it comes to dealing with many thousand volts, the number dwindles to evanescence. * * * * * In the region of pressures where coronal discharge is prominent, the situation is greatly complicated and insulation is a formidable question."

Yet insulation has been applied to conductors for certainly a hundred years, and it seems that current engineering development has not been sufficient. Just here some of us feel that invention is necessary, in this old and well-ploughed field; and that when Mr. Moody or some other transformer engineer devises a solution which proves in practice a thoroughly good one, good enough to become the best practice in the art, and to stand the test of time, he would be entitled to letters patent.

The editorial seems to me to fail to distinguish scientific investigation and invention; and to omit the qualification of the statute which grants letters patent for what is "new and useful."

If it simply confined its criticism to the granting of letters patent for so-called inventions which are not useful; or to the leniency shown to those who make random sketches subsequently swelled out by the arts of the patent solicitor to dominate the ideas of those who apply the underlying physical conception to some useful work, perhaps we could all agree with it.

NEW YORK CITY. T. J. JOHNSTON.

The Foucault Pendulum Experiments.

To the Editors of Electrical World and Engineer:

SIRS:—I have read with much interest the editorial in your issue of January 30 on the Foucault pendulum, and Mr. E. K. Adams' article suggesting means for reinforcing its action. These means, though very ingenious, do not appear to be entirely practicable. For purposes of instruction and for most any purpose to which this interesting pendulum can be put, a bob of soft iron would seem to do as well as any other metal and answer the same purpose as the inside coil which is suggested. It would also be easily possible to design a mechanism magnetically sensitive to the presence of the iron bob over the central coil, whereby the switching on and off of the electric current would be done automatically.

But it is also possible to restore the pendulum energy by mechanical means without thereby disturbing its plane of vibration. Force may be applied vertically at the point of suspension by gently and regularly lowering that point a short distance during the inward and correspondingly raising it during the outward motion of the pendulum, in which case the amplitude of vibration will be preserved. A suitable clockwork might regulate this operation. To regulate it by the pendulum itself I can think of no other means than the one above referred to, unless it be through the closing of an electric circuit by the point of the pendulum dipping into mercury when passing the center.

May I presume to make a suggestion? Would it not be a good idea to have a Foucault pendulum, equipped for continuous motion, at the St. Louis World's Fair? Such an exhibition undoubtedly would be an attractive feature of the Exposition.

CHICAGO, ILL. S. TIDEMAN.

Individual Motor Drive.

To the Editors of Electrical World and Engineer:

SIRS:—In your issue of March 12 there appears a letter from Mr. H. H. Cutler, of Milwaukee, criticizing my article on "Individual Motor Drive" in the February number of *Cassier's Magazine* and abstracted in your issue of February 20. Mr. Cutler takes exception to the rules that I have laid down for the determination of the size of motors for any given application, and, according to different methods of speed control used. He attempts to elucidate in a few words the causes that produce sparking in a motor with a weakened field. The elucidation is more or less lucid, depending upon the point of view, but any engineer who has had any considerable experience in the design of direct-current motors would probably consider that he has left a good deal unsaid, and has said a good deal that perhaps bears on the subject, but to a very insignificant degree. However, it is not important to the subject in hand to know just exactly what the innermost workings are that produce the result. It is sufficient to know that the results of operating a direct-current motor with its magnetic field considerably weakened, tend to make it spark; and it is a fact that motors operated under this condition do spark to a greater or less degree, depending upon the comparative load put upon them.

Mr. Cutler has substituted for the rules that I have laid down another set of rules. I quote the third rule as follows: "The horse-power capacity under variable field strength will remain constant." It would seem that it needs no argument to prove that this rule is not a rule at all. We have only to refer to another part of Mr. Cutler's letter to see that he does not believe it himself. He says: "It is certainly true of a great many makes of motors now on the market that they will actually develop the same horse-power at double their normal speed with weakened field, but most of them will spark badly at the commutator on the higher speeds when transmitting their rated horse-power, simply because they were designed to run at a constant speed." This quotation proves that a great many motors of the best makes have, as they should have, a certain margin under normal operation.

He states that it is only necessary to order motors specially wound in order to produce these phenomenal results. He lays considerable stress on a quotation which he received for a motor that would develop 5 hp at 300 r.p.m. with full field, and 5 hp at 1,200 r.p.m. with weakened field, without undue sparking at the commutator. This motor as normally considered was a 15-hp motor at 900 r.p.m. I have no doubt at all that he received such a quotation, as there are numerous instances in which such quotations have been made and in which such motors have been furnished; but in every case the result has been the same.

A great many designers of direct-current motors have attempted to hypnotize the motors in order to cause them to produce these results. It is not a question of who builds the motor, as Mr. Cutler suggests, because all motors will perform exactly the same if they are built with the same margins. Mr. Cutler seems to lay great stress on what he says the builders will guarantee to do, but he does not state any instances in which these guarantees have been fulfilled, nor does he state how a motor shall be designed, especially in order to meet these requirements. He does not make this statement, for the simple reason that it is not possible.

The writer knows from a long and bitter experience in the individual application of motors that these rules as given by Mr. Cutler cannot be maintained in practice. If rule three, as laid down by Mr. Cutler, could only be proven true, it would be a great boom in the individual application of motors, and not only in the individual application of motors to machinery, but to motors in general, as it would be perfectly possible to construct a motor for general purposes at a considerably less expense than is ordinarily involved; for this rule simply states that the amount of magnetic flux in the field of a motor is unimportant, and can be made anything, as it is only necessary to have some flux and as many conductors on the armature as will give the desired speed.

It does not seem necessary to criticize the other rules laid down by Mr. Cutler, as they are all based on this assumption, with the exception of the ones which refer exclusively to variable voltage.

CINCINNATI, OHIO. W. COOPER.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

DYNAMOS, MOTORS AND TRANSFORMERS.

Pulsations of the Direct Current of Synchronous Converters.—ELSAESSER.—An article illustrated by diagrams in which the author investigates by analytical methods why the direct current taken from a rotary converter is pulsating. He endeavors to show that the main reason of the pulsations is the superposition of the ohmic voltage drop for direct current and alternating current in the armature conductors. His main conclusions are as follows: Every single-armature converter with only one armature winding for direct current and alternating current produces a pulsating e.m.f. on the direct-current side, the cause being the superposition of the ohmic voltage drops of the direct-current and alternating-current sides. Compared with this, other reasons of the pulsations are of secondary importance only. The frequency of the alternating voltage which is superposed to the direct-current voltage is twice, three times, six times the frequency of the supplied alternating current for single-phase, three-phase and six-phase converters, respectively. The amplitude of the pulsations depends upon the load and upon the pole shape of the converter. With an open direct-current circuit (that is, with no load), there is always a pulsating increase of voltage. The period of pulsation is equal to that of the loaded converter. For the single-phase converter this increase of voltage varies between zero and a value approximately equal to the voltage drop of the direct-current machine. With polyphase converters this increase of voltage is always greater than zero, but smaller than the voltage drop of a direct-current machine. It is, therefore, incorrect to determine the e.m.f. of the converter from the voltage at the terminals with open direct-current circuit. The superposition of the ohmic voltage drop of the direct and alternating-current sides also manifests itself on the alternating-current side and produces not only a distortion of the voltage curve, but also a considerable decrease of the ohmic drop of voltage. The distortion is small in the single-phase converter, but becomes greater with the increase of the number of phases. A phase difference between current and e.m.f. on the alternating-current side is generally of no great influence upon the phenomena upon the direct-current side, but manifests itself considerably on the alternating-current side.—*Elek. Zeit.*, March 3.

REFERENCES.

Circular Diagram of Induction Motors Above Synchronism.—MÜLLER.—A mathematical article illustrated by diagrams. If the rotor of an induction motor is operated above synchronism, it returns current to the supply mains. The author shows that the well-known (Heyland-Behrend) circular diagram, if applied to the operation above synchronism, gives wrong results. His calculations are made by Steinmetz's symbolic method and show, for instance, that in the non-synchronous motor the current is always lagging in phase behind the e.m.f., while in the generator it may be leading under certain circumstances. The short-circuit current for a slip + 100 per cent. (i. e., with the motor at rest) is generally much smaller than at the slip—100 per cent.—*Elek. Zeit.*, March 3.

Alternators in Parallel.—BOHLE.—The first part of what seems to be a very long paper giving a summary of the whole subject. While in the parallel connection of direct-current machines it is only necessary to have equal e.m.f., in alternators it is necessary to have equal e.m.f's, equal periodicity and phase equality. These different requirements are discussed with the aid of diagrams and the action of the "synchronous force" is dealt with. The paper is to be continued.—Lond. *Elec.*, March 4.

High-Voltage, Direct-Current Dynamo.—A note on a direct-current machine built by the Company of Electrical Industry in Geneva (Thury) for experimental work in a technical college. It gives one ampere at 2,000 volts when running at 600 to 700 r.p.m. The commutator has 96 segments, condensers being connected in parallel to the armature coils, in order to avoid sparks. The exciting current is furnished by a small 110-volt exciter.—*Zeit. f. Elek.* (Vienna), March 6.

LIGHTS AND LIGHTING.

Mercury Vapor Lamp.—An article in which it is claimed that on account of the peculiar light of the mercury vapor lamp it is suitable only for purposes in which the distinction of colors is not important; it is, therefore, especially suitable for photography without colors, etc. The old Arons lamp is distinguished from the Cooper Hewitt lamp since the former had no automatic lighting arrangement and had to be started in a somewhat complicated way. Arons stated in a recent lecture that if in his lamp the arc has a length of 750 mm., the lamp consumes a voltage of 15, and that if the length of the arc is increased, the voltage also increases by 6 to 7 volts for each 100 mm. He mentions the peculiar fact that in his lamp, consisting of a reverse U tube, with mercury in both vertical tubes, the mercury evaporates from the anode over to the cathode, until the one vertical arm of the tube is filled with mercury, which is thus made to flow over. This produces a stationary condition without disturbing the light.—*Elek. Neu. Anz.*, February 15.

REFERENCE.

Long Life of Carbon Incandescent Lamps.—A note on some carbon incandescent lamps which had a life of 14,000, 21,800 and 17,000 active hours. In the second lamp the candle-power had, however, decreased from 32 to 9 and in the third from 25 to 5. While this long life of carbon filaments may be remarkable, it is not economical to use lamps for such a long while.—*Elek. Neu. Anz.*, February 15.

Power.

Swiss Water Power Plant.—Collischonn.—The conclusion of the long illustrated description of the Kubel water power plant. The power house contains four turbine-driven generators, each of 500 hp, two turbo-driven generators, each of 1,000 hp, and one steam dynamo of 1,000 hp. The generators have a stationary armature and a revolving field system and produce directly a voltage of 10,100. To protect the switchboard attendants against any accidents from the high voltage, the following method is made use of. All instruments, phase indicators, etc., are connected to a few coils separated from the other windings of the machine, and the voltage, thereby lost, is regained by a transformer which is primarily connected to the measuring coils and secondarily to the armature winding. If the ratio of transformation of this transformer is one to one, the primary and secondary currents are equal, so that the current measured by the instruments is equal to that of the machine. The e.m.f. measured at the instruments is to be multiplied with the ratio of the number of coils of the armature to that of the separated coils; the voltmeters are, of course, calibrated so that they give at once the voltage of the machine. A map is added which shows the distribution of power from the station. There are two main lines from which go off several branches; the most distant point is at a distance of about 23 km. from the plant. There are about 900 consumers of lighting current with a consumption equivalent to 17,000 lamps of 56 watts. There are connected to the plant 47 motors with 1,602 hp capacity, while 126 kw are used for 242 heating apparatus. In order to encourage consumers to use current for power purposes, four different tariffs have been devised to suit every possible customer.—*Elek. Zeit.*, March 3.

Electric Power in Ship Yards.—Brown.—An illustrated article on electric power in British ship yards, with special references to the northeast coast. From figures supplied by a shipbuilding firm which adopted electric driving in its early stages, he gives a comparison of the cost of power per "pound of wages paid" in the years 1894 and 1901; that is to say, before and after the use of electricity. In 1894 the cost for coal, gas and labor for driving the engines scattered around the yard was 8.66 pence per "pound of wages paid," and in 1901 the cost of coal, labor and other incidentals for producing the power electrically, was 4.88 pence per "pound of wages paid," or, in other words, the wages paid in 1901 were practically double those paid in 1894, and the cost for power was the same, and this in spite of a very great increase in the number and size of the machine tools employed, which, in the year in question, practically amounted in 1901 to six times what were in use in 1894. There are three systems in use; in the older ones 125 volts direct current is employed, in later ones 220 or 250 volts direct current, and some of the very latest installations employ three-phase currents at 400 to 440 volts. There is some advantage in the use of three-phase currents over the direct-current system, especially if a higher pressure than 250 volts be required, in view of the difficulty of lighting the offices from a two-wire, direct-current system at a higher pressure than 250 volts; but on the score of simplicity there does not seem to be any advantage on one side or the other, and though the question of maintenance naturally arises, as far as could be gathered from works with direct-current systems in use from 8 to 9 years, only a small amount of attention is required to the commutators and brushes. The principal repairs in both direct and alternating-current systems are in connection with the starting systems and regulating apparatus. The author describes several installations and the equipment of various machine tools.—*Cassier's Mag.*, March.

Engine Tests and the Effect of Superheating.—Morcom.—A paper on the equipment of an engine test house, as used by manufacturers for their own purposes, as well as to demonstrate guarantees, so as to avoid the inconvenience to a station engineer of having his station turned into an experimental apartment. A plant for testing combined sets for electricity stations is described, the general routine of such tests is given and special notes are added on temperature tests, exhaust, brake tests, the instruments and apparatus used, switchboards, and the benefit due to superheating. Concerning the latter point he says that on an engine properly designed to run under superheated steam conditions full advantage is taken of the improved economy with but little extra trouble in running. It is only in using superheat on an engine quite unsuited for the purpose that troubles are experienced. The point has sometimes been raised, that as clearance for expansion must be allowed in the pistons and valves on an engine designed for superheat, so if the superheat fall the engine will be very extravagant of fuel. Experiments have been made which prove that this is a mistaken notion. An engine designed to run with 250° superheat has been tested with dry steam at saturation temperature and the result shows that with these valves and pistons the engine is only 2.1 per cent. less economical than when fitted with valves as pistons designed for ordinary conditions. With a three-cylinder triple engine of 200-kw capacity, the steam consumption in pounds per hp-hour was determined as function of the degrees of superheat, and it was found that the percentage of improvement for any given rise in temperature is approximately the same at full and half loads. The gain due to 200° of superheat was found to be 41 per cent. The actual gain due to superheat is, of course, less than this, as extra lubrication and increased fuel consumption are required. The increased cost of oil for cylinder lubrication amounts to about 0.08 cent per 100 hp-hour, and is, therefore, a very small item. Fuel consumption trials run on a 522-hp triple-expansion engine with 160 pounds pressure and 26-in. vacuum gave the following figures: Fuel per hour with saturated steam, 1,193 pounds; in boilers with superheat, 833 pounds; in superheater to give a temperature of 600°, 173 pounds. Accordingly, the gain in fuel is 19 per cent. The fuel was slack of poor evaporative value. The superheater was very lightly loaded, and the lagging of the steam pipe was not so good as it might have been. Allowing for these points, it seems that a saving of, say, 25 per cent. might be expected by superheating to 600°. Another interesting trial taken on a 120-hp compound engine at 450 r.p.m. was on the influence of forced lubrication on the indicated horse-power at light loads. The engine was run free, and friction cards taken with oil pressure of 30 pounds, 5 pounds and 0 pound. The horse-powers in each case were 2.128, 2.409 and 3.333, respectively. This is interesting as showing that a great increase in oil pressure will not bring a correspondingly big advantage.—Lond. *Elec.*, March 4.

Earth Return in Direct-Current, High-Tension Transmission Systems.—An illustrated note stating that Thury made some years ago experiments in order to use the earth as return in his well-known direct-current series system. If in such a system the earth is used as return, 15 per cent. of copper weight is saved for the same percentage loss, or, if the same copper is used, the losses are reduced to one-quarter of their original value. The resistance of the earth is negligibly small for industrial currents. Only the contact resistances are to be taken into consideration; by proper arrangements they may be reduced at will (for instance, to one ohm). Recently Thury has suggested an arrangement in which the earth is used as the neutral wire in a high-tension, direct-current, three-wire system. —*Zeit. f. Elek.* (Vienna), March 6.

Labor Saving by Power Applications.—The whole number contains profusely-illustrated articles on this subject. Hunt writes on the world's great labor-savers and labor-servers from James Watt to George Westinghouse; Rose on the rise of labor through labor-saving machinery; Sweet on the prime-mover and its influence on the world's progress; Waitt on labor-saving devices as the basis of the railway's growth; Baxter on hydraulic appliances in the engineering industries; Moldenke on labor-saving machinery in foundry operations; Robertson on the development of power-driven machinery in mines; Bolton on mechanical auxiliaries to the economy of the fire room, and L. Bell on the relation of electrical inventions to human activity.—*Eng. Mag.*, March.

Steam Turbine.—Porte.—An illustrated paper read before the Dublin Section of the Brit. Inst. Elec. Eng. describes the construction and operation of the De Laval steam turbine.—Lond. *Elec.*, March 4.

Traction.

Swiss Railway.—The conclusion of the long and well-illustrated article on the electric railway between Freiburg, Morat and Anet. The third rail is used along the line, except at street crossings and in railroad stations. The third rail is placed alternately at the left side and at the right side of the track. There are, of course, two sliding contacts on the train, one on each side. The two sub-stations supply the third rail by an underground cable, the road being divided into three sections which may be supplied with current or disconnected at will from one or the other station. The equipment of the cars is described in detail.—*L'Eclairage Elec.*, March 5.

Single-Phase Traction.—EICHBERG.—The conclusion of his paper on single-phase railroads. The author gives several diagrams in comparing the behavior of two 600-volt, direct-current motors with that to two 6,000-volt, single-phase motors, based on the experimental runs with the Winter-Eichberg motor near Berlin. He concludes that the single-phase motor is able to fulfill the most rigid requirements of traction.—*Zeit. f. Elek.* (Vienna), March 6.

INSTALLATIONS, SYSTEMS AND APPLIANCES.

Voltage Regulation in Alternating-Current Systems.—MEYER.—The conclusion of his paper, the first parts of which have already been abstracted in the Digest. He discusses automatic voltage regulation and compounding. The first method dealt with is by means of mechanical influence on an exciter rheostat, which is shown in

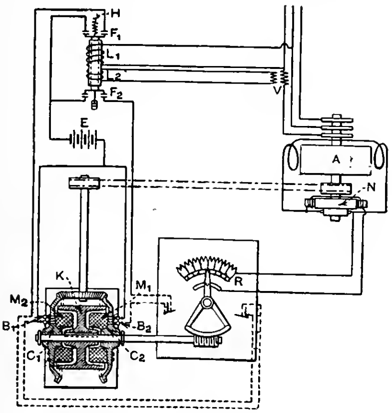

FIG. 1.—VOLTAGE REGULATION.

Fig. 1. *A* represents the alternator, *N* the exciter, *R* is the rheostat in the exciter field. Its handle is worked by means of a worm gearing from a magnetic clutch, *K*, which is controlled by the relay, *L*. The latter device is shown as a solenoid acting against a spring. In accordance with a lower or higher supply voltage either the spring or the solenoid will be more powerful, thereby closing the energizing circuit of M_1 or M_2, thus increasing or reducing the resistance, *R*. By adding a second coil, L_2, wound in opposition to L_1, and controlled from the secondary of a current transformer, *V*, the primary of which is in series with one of the main lines, over-compounding with increasing current can be obtained. This scheme has been successfully used in a number of plants where the nature of the load introduces only very gradual changes in load. For all other purposes it is not recommended, since the time lag between action and reaction is too much to allow a satisfactory regulation of the voltage. A second method is the use of a pulsating excitation in the exciter field. The device of Tirril, of the General Electric Company in America, belongs to this class. In the same the control of voltage is obtained by rapidly opening and closing a shunt circuit across the exciter field rheostat, thus giving the exciting current of the exciter a more or less pulsating character. The frequency of the make and break of this circuit is controlled by the voltage and, if desired, also by the current of the generator, and varies from about 1 to 20 per second. The apparatus is described in detail. It is well known in this country since more than 100 of these regulators have been installed here within the last 18 months. A third class of regulation is by means of influence on the armature reaction of the exciter. The compensated generator of the General Electric Company, of this country, of which about 3,000 kw are in successful use in sizes from 50 to 500 kw, belongs to this class, as also does the compound generator with special exciter of Le Blanc, which was exhibited at the Paris Exposition. However, the complications inherent to the arrangement of the latter have apparently prevented its commercial introduction. The fourth method discussed by the author is compounding by means of rectified or low periodicity alternating currents. Older arrangements of the General Electric Company and the Westinghouse Company and Ganz & Co. belong to this class. These alternators are provided with a commutator and a series winding on the field in a manner similar to compound-wound, direct-current generators. The new arrangements of Latour and Heyland also belong to this class.—Lond. *Elec.*, March 4.

Water Resistance.—MORCON.—In a paper on the equipment of an engine test house the author says that after considerable trouble and expense in connection with wire resistances both in wooden and iron frames, the following form of water resistance for taking up the load was devised: The poles are of iron, arranged in wooden tanks. Water from a neighboring canal is passed continually through the tanks by a bye-pass on the condenser circulating pump, and flows out over a weir. The poles are connected to a load-adjusting switchboard, and can be coupled into the load in many combinations. Three tanks are used for different ranges of voltages, and these ranges are further divided by adjustments of the outflow from the tank. Specially subdivided tanks are used for polyphase work. The first experience when using a water resistance was not very satisfactory. The apparatus consisted of an iron tank about 3 ft. wide and 6 ft. long, with two large iron plates for the electrodes. This tank did not last very long, for the current, as well as passing from plate to plate, found a shorter passage by way of the sides and bottom of the tank. An improvement of this arrangement was a large wooden tank 4 ft. wide by 10 ft. long and about 4 ft. deep. Into this were fitted four hollow cone-shaped castings, large and upwards. Inside each of these cones was a smaller one, suspended from above on a screwed spindle and hand wheel. The outer cone was coupled to one terminal of the dynamo on test, and the inner through a flexible lead to the other terminal. Load could then be varied by raising or lowering the inner cone on the screwed spindle. It was necessary to keep the water level a little higher than the top edge of the outer cone, so that the heated water in the space between the cones might rise naturally and flow away. This arrangement gave very satisfactory results; in fact, some cones are still in use which were fitted about 18 months ago. For higher voltages it was proposed to use a metal rod dipping into the water at the center of the cone, but the conducting area of water to the outer cone was too large and the length of water resistance too small for many machines. Accordingly, a wooden trough of small cross-section and great length was designed for high-voltage work. The use of wooden troughs did away with the need for conical poles, and it is now found more useful to substitute iron plates fixed at the top to flexible terminals and movable on insulated rollers along wooden runners. The load can thus be varied by sliding the plates along so that the cross-section between them is varied. By using a considerable number of smallish plates a very flexible load is obtained, and if care be taken with the circulating arrangements a very steady load results.—Lond. *Elec.*, March 4.

ELECTRO-PHYSICS AND MAGNETISM.

Thermoelectricity of Iron and Steel.—BELLOC.—A paper presented to the French Association for the Advancement of Science. Concerning the temperature coefficient of the thermo e.m.f. of steel-platinum couples (comprising the Peltier and Thomson effects) he arrives at the following conclusions: The curves representing the same show a minimum common to all couples near 380°, the minimum being 8.75 microvolts. All curves reach a maximum at a higher temperature, but the position of this maximum depends upon the contents of carbon in the steel; the temperature at which the maximum occurs varies between 680 and 820° and the maximum itself between 16 and 20 microvolts. Each curve shows afterwards another minimum at a temperature about 120° above the temperature at which the maximum takes place, and the second minimum differs from the maximum of about 4 microvolts.—*L'Eclairage Elec.*, March 5.

Selenium Cells.—BERNDT.—An account of experiments in which the author reaches the conclusion that the decrease of resistance of a selenium cell, when lighted, cannot be explained by a chemical action. He offers the hypothesis that crystalline selenium exists in two modifications which are in dynamic equilibrium with one another. When the cell is lighted this equilibrium is changed, but in the dark the original condition is gradually brought back. If, however, the cell is roughly handled, then so much is formed of the one modification that a part of it assumes a stable state of equilibrium and does not return to the former condition in the dark.—*Phys. Zeit.*, March 1.

Energy of Röntgen Rays.—Wien.—Of all hypotheses on the nature of Rontgen rays the author considers as the most plausible one that of Wiechert that they represent electromagnetic oscillations of short duration, caused by the quick retardation of the negative electrons hitting the surface with great speed. On this basis the author calculates the energy of Rontgen rays, making special assumptions. If in a discharge tube 0.001 amp. electricity is transported in the cathode rays, this makes 4.1×10^{15} electrons per second, and the total energy changed into Rontgen rays is 0.000125 watt. Since the radiation of a theoretically black body of 100° C. to one of 0° with 1 sq. cm. surface is 0.073 watt, the energy of the Röntgen rays is about 500 times more.—*Phys. Zeit.*, March 1.

Polarization of Röntgen Rays.—Lieben.—The author had formerly investigated the effect of Rontgen rays upon heavy metals in the vacuum. Since Blondlot has found that every Röntgen ray tube emits polarized N-rays, Lieben has now investigated whether these N-rays have any influence on the effect found in his former work and attributed to Röntgen rays. For this purpose he eliminated the N-rays by interposing a layer of water of 3 mm. thickness. This acts as a filter, absorbing the N-rays, but allowing the X-rays to pass through. He obtained the same results as before, so that his former results were not influenced by the N-rays. He found, however, that his former observation of the polarization of Röntgen rays was wrong, being due to improper arrangement of his former experiments.—*Phys. Zeit.*, February 1.

Electrodeless Ring Currents.—Hærden.—An account of experiments in which he used an evacuated electrodeless tube, filled with mercury vapor, the pressure of the vapor having such a density that about 5,000 volts were necessary to obtain a light effect in the tube. Some windings of a cable were placed around the tube and the oscillating discharges of a condenser of about 0.004 microfarad were conducted through them. On the other side of the condenser, which was charged with an alternating current of about 35,000 volts, there was a mercury air-gap, the other connections being as usual. When set into operation the tube showed a strong light effect and the glass became heated. In other words, the lamp behaved as though 5 to 6 amp. direct current were passing through it. He shows, however, that any currents directly induced in the mercury vapor are of very little importance for the phenomenon which is rather an electrostatic one, the high e.m.f. due to the impedance of the primary windings charging the glass tube on the outside and influencing a charge on the inside of the tube. These inside charges afterwards discharge through the vapor and cause the lighting. In another article he describes an arrangement in which a pure induction effect is produced and no static phenomena take place.—*Phys. Zeit.*, February 1.

REFERENCE.

N-Rays.—Charpentier.—An account of experiments in which he found that the transmission of N-rays can be accomplished not only by conducting substances, but also by bad conductors such as glass and wood, although to a somewhat smaller extent. He has, in conjunction with Blondlot, even succeeded in transmitting the fluorescence across an air-gap between two condenser plates.—*Comptes Rendus*, February 5; abstracted in Lond. *Elec.*, March 4.

Electro-Chemistry and Batteries.

Dielectric Constants.—Schlundt.—In former investigations of a great number of inorganic solvents he had tested the Nernst-Thomson rule, according to which a close parallelism exists between the dissociating power of solvents and their dielectric constants. He found a number of exceptions to the rule and a number of new examples which followed the rule. The solvents studied at that time, however, follow the rule in a general way, although the parallelism between the ionizing power and the dielectric constant was far from close in several instances. The author has now investigated the dielectric constants of some halogen compounds of phosphorous, arsenic and antimony. The value for the dielectric constant for the compound in the solid state is less than the value for the liquid and the structure has a great influence on this difference. Most of the compounds studied follow the Nernst-Thomson rule.—*Jour. Phys. Chem.*, February.

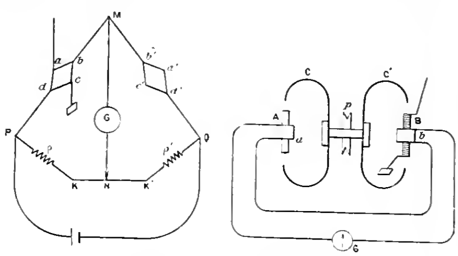
Storage Battery.—A note on the Lacroix storage battery, made by a French company. The wire of the very fine webbed network from which the plates are made consists of a special alloy, called pontinium and consisting of a thousand parts of lead, 15 parts of tin and 1 part of sodium. In spite of the very thin but nevertheless very resistant network of the plate, the active mass is claimed to be kept very firmly in it, so that it can drop out.—*Elek. Neu. Anz.*, February 15.

Units, Measurements and Instruments.

Electrical Methods of Measuring Temperature.—Callendar.—An abstract of a lecture in which he said that the electrical methods for measuring temperatures are more accurate, speedy and generally convenient than the other methods yet known, and are at the present time used almost exclusively in research work. There are two kinds of electrical methods, one based on measuring the resistance due to the change of temperature and the other on measuring the potential difference at the junction of two different metals when it is heated. The first method is more accurate, as a rule, than the second, especially for low temperatures, and has the further advantage of giving readings almost instantaneously. It is also very convenient for measuring mean temperatures. The second method, using a thermo-couple, is valuable for determining the temperature at a particular point. He discussed briefly the methods for determining resistances, pointing out the great accuracy of the zero methods, and drew special attention to the proper way of connecting up the very fine platinum resistance wire of the thermometer to the resistance box. The proper way to do is to make the connections so that the current passing through the resistance wire of the thermometer also passes through the resistance in the third arm of the bridge. The current passing through the wire is thus small, and the error due to its heating the wire is reduced to a minimum. He described an electrical temperature recorder which may be used for various purposes; for instance, for recording the duration and intensity of sunshine. It is much more sensitive than the burning-glass method, which is generally used for this purpose.—Lond. *Elec.*, March 4.

Telegraphy, Telephony and Signals.

Electric Wave Detector.—Tissot.—A paper presented to the French Association for the Advancement of Science. The author has found that the bolometer may be used as a detector of waves over a distance of several kilometers. His arrangement, shown in Fig. 2, consists essentially of two identical systems of thin platinum wires, *a, b, c, d* and *a', b', c', d'*, arranged on the branches of the Wheatstone bridge, *M, N, P, Q*. The bridge is brought into equilibrium by means of the two coils, *S* and *S'*, immersed in the same bath of petroleum, and connected together by the sliding contact, *K, K'*. The vertical wire is connected to *a*, and *c* is connected to earth. A sensible galvanometer is used in *G.* The author uses one of the Thomson (Broca-Carpentier) type, the coil of which has a resistance equal to that of the other branches of the bridge. The quantity measured is the total energy received by the vertical wire. For other purposes the author has employed a modification of the Rutherford-Marconi magnetic detector. Observations are made by a gal-



FIGS. 2 AND 3.—ELECTRIC WAVE DETECTOR.

vanometer, instead of a telephone. The instrument, shown in Fig. 3, consists essentially of a double detector, each consisting of a magnet, *C* and *C'*, a primary coil (*A* and *B*) with steel wires and a secondary coil (*a* and *b*). The magnetic, *C* and *C'*, are mounted on the same axle. The coils, *a* and *b*, are connected in opposition to a sensible ballistic galvanometer, *G*, or to an electrodynamometer of the Bellati type. The arrangements are so made that there exists perfect equilibrium of *G* during the rotation of the system. This equilibrium is destroyed by the arrival of an electric wave if the coil, *B*, is connected at one end to the vertical wire, and with the other end to earth.—*L'Eclairage Elec.*, March 5.

MISCELLANEOUS.

Cure of Cancer by Radium.—WALSH.—An article in which the author states that while it is not yet possible to speak with certainty as to the exact therapeutic value of radium, yet he is confident that by its means it is possible to modify profoundly and in some cases apparently to cure surface rodent ulcers and epitheliomata. The method of application is to enclose the radium in a small India rubber capsule with a mica window or in a small glass tube. The radium is used most conveniently in the form of the bromide and should be of good quality. The small tube containing the salt must be placed directly in contact with the ulcerating surface. It apparently is of no use if applied to the unbroken skin surface. The action of the radium is strongest at the immediate point of contact and lessens in power according to the distance from that point of contact. The radium may be applied for a quarter of an hour or more up to 30 or 40 minutes, but the length of application should be most carefully regulated by individual results. A reaction occurs usually on the eighth day of treatment and may be due to the formation of an antitoxin. The radium cure has even been applied to a rapid malignant invasion of the upper throat. Four small sealed tubes with radium bromide were fastened at the end of a curved holder and enclosed in a covering of India rubber extemporized from a finger stall. The throat was then cocainized and a gag inserted between the teeth. A light thrown into the mouth by a mirror enabled the physician to pass in the radium and press it with decision on the desired part. By this treatment the ordinary process of the disease has been profoundly modified, if not, as is hoped, even been arrested.—Lond. *Elec.*, March 4.

New Books.

MY AIR SHIPS. By A. Santos-Dumont. New York: The Century Company. 400 pages, 75 illustrations. Price, $1.40.

This is not exactly a scientific treatise on aerial navigation, nor does it profess to be. It is rather a chronicle of successive attempts to solve some of the many problems connected with the subject, including more particularly those of dirigibility, and incidentally one picks up a lot of practical information from the narrative unfolded in these simple and direct pages. Mr. Santos-Dumont has, indeed, achieved no small measure of success from his courageous and persistent efforts, and one wonders that the young Brazilian is really alive to tell the tale. The probability is that had he been a few pounds heavier he might not have traveled so fast and so far in the air, modern flying, like modern fighting, being distinctively in favor of the small man. In these later attempts at airship steering, electricity does not play so much of a part as it did, for example, in some of the earlier work of Krebs and Renard, and the Tissandier Brothers, who employed motors and accumulators; but in real hard work the turn of electricity may come again. Mr. Dumont makes incidental reference to his conference with Mr. Edison on the subject.

LA TECNICA DELLE CORRENTI ALTERNATE. 2 volumes. By Guiseppe Sartori. Milan: Ulrico Hoepli. Vol. I, 336 pages, 260 illustrations; price, 8 lire. Vol. II, 495 pages, 293 illustrations; price, 12 lire.

These two volumes taken together form the best text-book on alternating-current theory and practice that we have yet seen in the Italian language. The writer has a clear and descriptive style. There are abundant illustrations, diagrams and numerical examples.

Volume I is written on the practical side of the subject, with curves, diagrams and illustrations of machinery, but with scarcely a single algebraic equation. The subjects treated are single-phase and polyphase currents, induction coils, transformers, alternators, synchronous and asynchronous motors, both single-phase and polyphase, converters and transmission lines. The information given is simple, definite and reliable.

Volume II is devoted to the engineering mathematics or technical algebra and arithmetic of the same subject. In this direction vector methods and diagrams are plentifully introduced. The treatment is excellent and clear. A number of numerical examples are scattered throughout the work.

The first volume is well adapted for study by those who are not interested in the quantitative relations of the subject. The second volume is an excellent text-book for students of alternating-current engineering. To all interested in this subject and to whom the Italian language is familiar, the work is to be strongly recommended.

THE UNIVERSAL ELECTRICAL DIRECTORY. By J. A. Berly. London: H. Alabaster, Gatehouse & Co. 1,446 pages. Price, 10s.; U. S. A., duty free, $3.75.

This valuable publication has now reached its twenty-third year of annual issuance, and has again been thoroughly revised and brought up to date. The sections are as usual: Continental, United States, Colonial and General, British, and Geographical, each alphabetical list of names being accompanied also by a classified list as to manufacturers, engineers, etc., so that the finding can be easily accomplished in connection with any name wanted. The American list is very full and complete and is valuable also by giving telephone calls or cable addresses. In fact, one feature of value of the book is the number of cable addresses given in connection with all the lists of names. The book has now reached a total of nearly 1,500 pages, large octavo, a simple fact which will convey an idea of the immense amount of work put upon the compilation. The preface discussing the outlook does not speak very cheerfully with regard to the past year in England, but is a little more hopeful with regard to the outlook during the present year. It points significantly to the fact that electric traction is beginning to boom, not merely with regard to street railway enterprises, but those of larger range and scope. England is indeed an ideal country for the conversion of short trunk railroads from steam to electricity, and although the conservatism of the country is notorious and is a good factor in a great many instances, it is hard to believe that it can stand much longer in the way of this needed change of motive power. England is a country where steam locomotion has been of inestimable value, but has brought in its train a great many evils, some of which electricity can certainly cure or ameliorate, to say nothing of its own inherent advantages not possessed by its elder competitor.

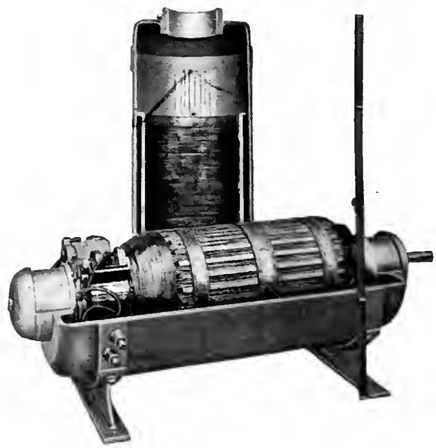
The Dialt Motor.

By N. H. Edgerton.

Now while public attention is turned to alternating motors for single-phase circuits, and especially for street cars, interurban and very long-distance work, the following description of a motor that embodies a rather novel departure from the ordinary lines of modern construction may not be without interest. This motor, which is now just appearing commercially under the name "Dialt," did not in its early stages have the advantages of great mechanical skill, nor has it had the admirable engineering touch of Mr. Lamme, yet I am convinced that it is laid upon lines that will add materially to the perfecting of the electric motor for nearly all practical purposes.

The distinctive features are that it employs a wireless field; that each field is completely isolated magnetically from every other field, and that with a given potential it will operate on any current, with little regard to quality or condition.

The construction is exceedingly simple. A preferred form is to have the cylindrical frame of diamagnetic metal, divided into two halves, longitudinally through the axis, hinged together at the back, and suitably locked in front. In each one of these semi-cylinders is fastened half of the field equipment, whether it be bipolar or multipolar. At each end of this frame a suitable bearing is arranged so that the center of the armature shaft shall be the central line of the structure. This allows of the easy withdrawal and replacement of the armature, as the bearings also divide on line; the cups being carried in the upper half of the shell, thus exposing the shaft journals when the top is thrown back. The fields themselves are formed of circular laminations of soft steel or charcoal iron of suitable gauge insulated from each other in the usual manner or by tinning. When this latter method is employed, the laminæ of each field may be assembled together and sweated into one piece; laminated as to its magnetic function, but solid as to its mechanical structure. The question as to whether this tinned construction of the field gives rise to eddy currents therein, will have to be answered at a later day, but as the whole surface is subjected at all times to the same magnetic stress, it would seem from a theoretical standpoint that the inequality of magnetization necessary to produce such currents is wanting. Should it be found, however, that eddy currents are developed, the ordinary method of insulating the laminæ can readily be adopted. When the lid is closed down about the armature, it will be observed that with all the fields of the same dimensions and the armature wound symmetrically, there will be contiguous to, and operative upon, each field, exactly the same number of armature turns. Consequently, with any given current flowing through the armature the ampere-turns will



DIALT MOTOR.

likewise be the same and the resulting magnetization of each field the same and likewise the reaction of each field upon the armature the same.

Observing it first as a direct-current motor, we find that this construction frees us at once from two very important conditions. The first is that, having no windings, the fields are capable of being used on any voltage without change; that is to say, if it becomes desirable to change from a higher potential, say, of 550 volts to 220 or 110, or even 50 volts, or visa-versa, it is only necessary to rewind or obtain an armature of that voltage, leaving the frame fields without change. The second is that there can be no short-circuiting or burning out of the field coils or any complications between the field and armature circuits, which will happen even in the best equipments as at present installed. This feature will undoubtedly interest all those having motors under heavy service on rough roads and in all conditions of weather.

As the windings of the armature are parallel with the shaft and the laminations of the fields are at right angles thereto, it is also obvious that the armature coils are in the best position for making an electromagnet out of each separate laminæ and consequently a compound electromagnet of great power out of the assembled laminæ.

As a corollary, this machine will act as a generator for direct current, building up and energizing itself from the residual magnetism of the fields, without making any change except to swing the brushes to the opposite point of commutation or else (letting the brushes stand in the same place) drive the machine in the opposite direction. The reason for this is that by isolating the fields, so arranged, the action of the armature coils on the fields is localized, or, so to speak, concentrated in the fields themselves and not dissipated and lost in the yoke; in fact so sensitive are the fields to the armature current that I have seen an armature weighing 100 pounds wound for 88 volts and 30 amp. start up under the application of 4.5 amp. at 10 volts, or 45 watts, and run at 250 turns on 25 watts, equal to an expenditure of one watt for every 10 revolutions. It will be noted that as the armature circuit is the exciting circuit of the fields also, and that any increase of the armature current and magnetization, will be followed by equal increase in field magnetization, the motor has the chief characteristics of a series motor, namely, variable speed with variable load, but of course without the wire losses of the field windings due to resistance counter e.m.f., etc.

The armature may be any one of the usual forms, either ring, drum or barrel, either toothed or plain, providing the windings of the armature are parallel with the shaft as mentioned above. A preferred form is to have the teeth cut in the form of an acute equilateral triangle, with the apex of the angle in the circumference of the armature and even with the outer layer of wire. The reasons for this are, first, to present to the field the greatest number of ampere-turns so as to realize the maximum magnetization of the fields; and, secondly, to minimize the iron loss in the armature due to the bunching of magnetic lines on the edges of the teeth, especially when using alternating current.

It will be seen from the foregoing description that this construction supplies a motor for direct current having series characteristics and especially well adapted to varying loads, because the current increases automatically with the load, the magnetization with the current, and the torque as the square of the current.

It is not, however, till we take up the motor to apply it to the alternating current that the full significance of its peculiarities dawn upon us. We have seen above that the field construction is such that it is independent of the armature windings so far as potential of current utilized by the armature is concerned; that is to say, if you take two armatures of equally good mechanical construction, one of which is wound for ten volts potential and the other for ten hundred or any intervening potential, and supply the required current to them, replacing one by the other alternately within the fields, the operation of the one will equal that of the other per watt energy employed. This discloses the fact that the armature is the controlling member of the combination and that the field adapts itself to, and responds automatically to, the conditions for the instant existing in the armature.

Take now an armature that has been running on the 110-volt direct current with its proper fields and supply it with 110 volts single-phase, alternating-current within the same fields; without having even changed the plane of commutation the motor will rotate as smoothly and evenly as with the direct current and the torque will be in the same direction, but will change by changing the position of the brushes. Now, supply two-phase currents to the same potential and the same result is obtained, and so also with other polyphase currents and for the reason stated, that the field responds instantly and automatically to every change of current condition in the armature. The value of this proposition in electrokinetics cannot well be overestimated. Especially is this the case in electric traction. For example, the instance narrated in a late number of the *Street Railway Journal* (and there are many such) where an aggregation of trolley companies combined their interests for the completion and operation of a long-distance line, using their individual plants over their individual roads and compelling their passengers to change cars at their termini. This transfer nuisance would be entirely done away with by such a motor, as the cars could then be run from section to section over the whole road.

As the question of the weight of the single-phase alternating motor is receiving considerable attention, it might be well to state that the Dialt motor is lighter in construction per unit of horsepower developed, for the following reasons: First and principally, because the large annular laminated ring-yoke uniting all the pole pieces is omitted entirely, while the radial depth of the poles themselves is limited to about that used for the field winding in the single-phase motor. There is, therefore, a saving in weight of the entire laminated annulus from which the pole pieces project, and this in large machines is a matter of considerable moment. In the armature there is probably no saving in weight, for the armature of the Dialt motor being relied upon to fully magnetize the field, is allowed a third more ampere-turns than in the ordinary field-wound, direct-current machine, it having been found that this increase is sufficient to insure saturation of the fields at 40 per cent. overload. There is also an elimination of the entire weight of the field windings, whatever that may be, which still further lightens the construction of the Dialt motor.

Both these motors then have reached the same result, namely, satisfactory operation on the single-phase current, but by different ways. They are also in many respects similar. We find in both the same extra-sized powerful armature, the same disposition of the poles about the periphery of the armature, and the same careful lamination of the pole pieces; each one is designed in its own way to produce the same result; that is, the concentration of magnetic energy on the faces of the pole pieces, the one doing it by means of toothed or grooved fields wound with their appropriate field coils and energized by current through those coils; the other, the Dialt, accomplishing the same result by smooth-faced unwound fields, each one isolated from all the others and energized by the current flowing through the armature coils. The one is based upon carefully observed facts and the most accurate calculations; the other on the careful disposition of the iron of the pole pieces to receive a maximum of magnetization from a minimum of current.

Electrically Equipped Parlor Car.

The accompanying illustrations show the electrical arrangements of a handsome parlor car recently supplied by the Barney & Smith Car Company, of Dayton, Ohio, to the Erie Railroad for its Tuxedo service. In addition to an unusually complete installation of lamps, the circuits are so arranged that the illumination can be graduated over a very considerable range, and the car is supplied with electric fans and a ladies' hair-curling outfit.

The car is wired throughout with No. 12 wire for 1 per cent. loss at 25 volts. The dynamo and battery wiring to the switchboard is of No. 1 cable run through heavy canvas hose and strapped to the bottom of the car. From the switchboard a double-circuit, two-wire system is used, by means of which each side from the center line of the car is supplied with a complete system. There are 15 circuits, all told, as follows: Eight to the center fixtures, four on the two deck sills, two for the three fans and one for the curling-iron heater at a ladies' dresser.

FIG. 1.—VIEW OF INTERIOR OF CAR.

One side of each circuit unites in a common return or negative main at the switchboard. The other, or positive sides of the lighting circuits, are connected single-pole in pairs through double-pole Bryant switches and double-pole plug cut-outs, thereby keeping the circuits separated, and at the same time enabling the two sides (right and left) of the car to be operated simultaneously.

The fans and curling-iron heater are on independent circuits. Each fan has in the wall near it a Hart flush electrolier switch which is so connected with the fan resistance as to enable three speeds of the fan to be obtained. By the above system of wiring it is possible to get in the main part of the car on the four auxiliary or day circuits any number of lights from one to ten, and by bringing into service the other eight circuits almost any number of lights from one to forty-six may be put in service.

The main switchboard connections are on the front and made up

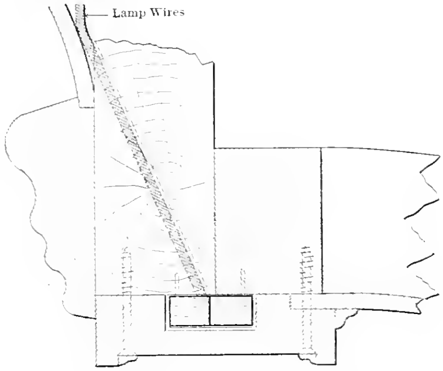


FIG. 2.—DIAGRAM OF WIRE CLEAT.

of bar copper, formed in shape and taped, and then several taped together; thus in case of disconnecting each section will remain intact. The wires are run in metallic cleats and taping in grooves in

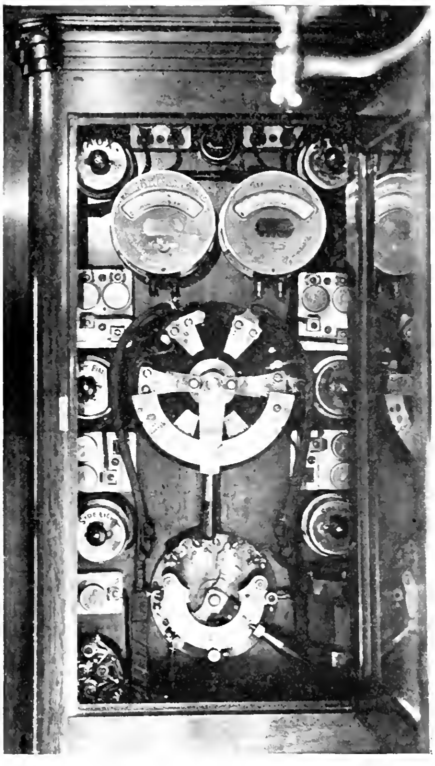

FIG. 3.—SWITCHBOARD ON CAR.

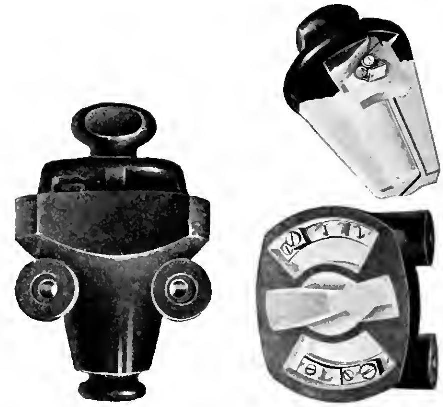
the soft mould, which is screwed to the deck sill, as shown in Fig. 2. All leads in branching therefrom pass up through a mullion over the deck openings to the center fixtures. Six hundred feet of No. 1 cable with over 3,000 ft. of branch and lamp conductor make up the wiring, and 68 8-cp. 25-volt clear, spherical globe lamps are installed. Three 12-in. Diehl fans and one curling-iron heater complete the electrical equipment. The generating and storage battery equipment is of the Gould type. Mr. D. D. Tate designed and installed the switchboard and circuits.

Transformer Primary Cut-Out.

An improved form of a transformer primary cut-out designed to protect the high-tension side of transformers is being introduced by the Westinghouse Electric & Manufacturing Company. It is made entirely of porcelain, and its form is such that it has high insulating and arc-breaking qualities. The plug to which the fuse is attached projects between the terminals, the upper end of it rising well into the top of the block and interposing an effective barrier, and thus making it impossible to maintain an arc. The fuse is eleven inches in length, making a long break, and is so placed that the vapors of a discharge are blown down and out of the device and away from the terminals.

The line wire is carried directly to the top of the device and attached to it as to an ordinary insulator, which it thus displaces. To reach the terminal the wire must be bent around the edge of the block and is so supported in an angle between the terminal post and



FIGS. 1 AND 2.—TRANSFORMER PRIMARY CUT-OUT.

the porcelain case that it cannot be loosened by any swaying of the wire in the wind.

The plug enters from the bottom. When it is raised into place a partial turn draws the knife blades on the plug into the jaws on the block, preventing the plug from dropping out or being blown out.

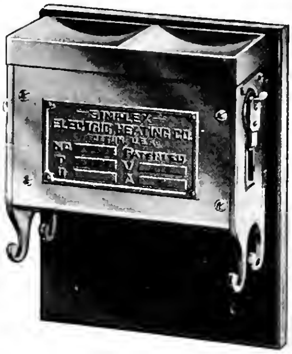
All live parts are protected from the weather by the projecting edges of the block, and by placing the terminals well above its lower surface, with no apertures in the side or top. A bend in the fuse wire brings it into plain view at all times, and it is thus possible to observe its condition without removing the plug, guarding against any liability of opening the circuit when there is a current upon the line.

It is fastened to the cross arm or other support by two screws, passing through porcelain tubes which form a portion of the block. It has a rated capacity of 2,500 volts, 30 amp., and is small, light, easy to install and to re-fuse.

Electric Heat in Theatres.

The effort to reduce theatre hazards to the minimum on the part of owners, managers and insurance companies has made a demand for electric curling iron and grease paint heaters so as to enable gas to be eliminated from stage dressing-rooms. In addition to its previous product in this line, the Simplex Electric Heating Company has recently brought out a new type of combined grease paint and curling iron heater. While it is a combination device, the heating of the grease paint is independently controlled.

The grease paint heater is divided in two sections and forms the top of the device and is controlled by a quick opening switch on the left side of the device. The curling iron is inserted at the right side and the current is automatically turned on or off by the action of putting in and removing the curling iron. Hooks are provided for hanging the curling iron when out of use. The device is polished nickel finish, mounted on enamel slate and arranged to fasten to standard outlet box or on wall as ordered. This product is the result of the co-operation of an expert theatre electrician, George A. Mc-



STAGE DRESSING-ROOM ELECTRIC HEATER.

Curdy, of New York, and the company's engineers, and has been installed in several new theatres.

The company's combination curling iron and grease paint heater, known as No. 1280, is in extended use, and the two types are calculated to meet all requirements.

High-Voltage Oil Fuse.

OIL FUSE.

The accompanying illustration shows a high-voltage oil fuse made by the Anyun Lamp & Electric Company, of Buffalo, N. Y. The fuse is connected to brass rods as shown, and brass terminals are screwed to the latter at the end caps. At the top are air tubes, which also serve for the introduction of the oil.

The glass tube is partly filled with a high grade of transformer oil, which is poured in through one of the air pipes, just enough oil being used to completely submerge the fuse wire. When a short-circuit occurs, the oil enters the space between the two ends of the broken fuse wire, and effectually smothers any arc. The oil becomes darkened after a short-circuit, the discoloration being caused by gases, but resumes its natural color after standing some time. Rubber discs and washers allow expansion and contraction of the glass, and prevent the oil from leaking out. The air space between the surface of the oil and the upper cap allows the oil to rise in the case of a very severe short-circuit, and reduces the amount of pressure against the glass, which is very thick and tough, the air pipes allowing the gases to escape. The fuse is self-indicating, the fuse wire being visible until a short-circuit occurs, which, as stated above, is manifested by the discoloration of the oil. A fuse can be refilled at the power house as often as it blows out, thus practically eliminating any further expense after the fuse has once been installed.

Electricity in a Modern Hospital.

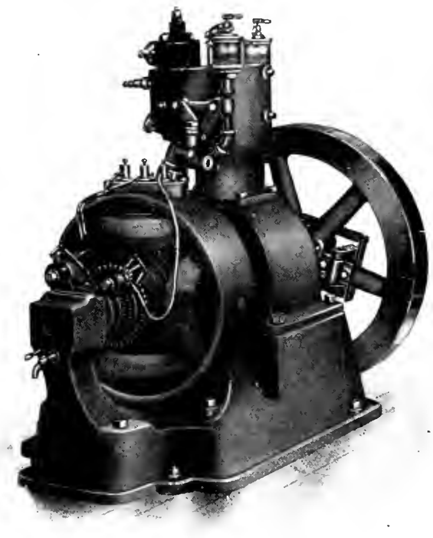
One of the largest hospitals in the country has just been opened in New York City, namely, the Mount Sinai, occupying an entire square block, between Madison and Fourth Avenues and One Hundred and One Hundred and First Streets. There are ten buildings within this space and provision has been made for 456 beds. The equipment is of the most modern and up-to-date character possible.

The electrical service includes 6,000 lamps and 200 hp in motors. There are five General Electric direct-current generators directly connected to five Ball & Wood engines. Three of the units are of 100 kw each and two of 50 kw each. The marble switchboard in the dynamo room is 28 ft. long, 8 ft. high, with bronzed frame and with a grille. A very interesting feature is the use in all the rooms in the private hospital and in all the wards of the Sayles regulators for turning the electric lights up and down. This feature of convenience is very highly appreciated and is now becoming quite common in hospital work. The laundry is operated entirely by electric power and heat, all the ironing being done with electrical irons. There is also a complete interior telephone system of 125 stations and an intercommunicating system of 50 stations. All the clocks, 88 in number, are operated electrically, and there is a storage battery equipment operating telephones, clocks, watchman's detectors, bells, etc., a motor-generator being installed for use in the day time and the battery being a reserve in case of break-down. Everything is in duplicate. There are all told about 100 miles of wire in the building for various purposes. The Charles L. Eidlitz Company was the contractors for all of the electrical equipment.

Lighting Set for Small Yachts.

The compact electric generating set illustrated below has been designed for use on gasoline launches, yachts and sailing vessels, where there is no means of driving a steam engine. The engine of this generating set is a gasoline engine of 2½ hp. The dynamo is of 1-kw capacity and furnishes 10 amp. at 110 volts. The speed of the dynamo is 750 r.p.m. Flexible couplings, etc., are avoided and the armature is mounted on a sleeve which slips over the crank shaft and is held securely in place by means of a long key.

In order to make the set complete, the circulating pump is attached directly to the engine and is driven by means of an eccentric from the cam shaft. The governor is contained in the fly-wheel and is of such sensitiveness that the speed is maintained within 2 per cent. from no load to full load. As weight is to be considered on shipboard all parts are made as light as possible consistent with strength.



GENERATING SET FOR YACHTS.

The dynamo frame is a steel casting of highest permeability. Bedplate and engine frame are made light, but strong enough for the purpose.

The weight of the complete plant is 475 pounds, including fly-wheel and all accessories. The floor space occupied is 20 in. by 34 in. and height is 30 in. The space occupied is so small that this little plant can be placed in an out-of-the-way corner where it will do its work faithfully and conscientiously with not much more noise than a sewing machine. It will furnish sufficient current for lighting 20 incandescent lamps of 16 cp. or a 1,500-cp searchlight and eight or ten incandescent lamps. The manufacturer is the Carlisle & Finch Company, of Cincinnati, Ohio.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—There was marked improvement in prices of stocks and general activity in speculation, largely on short covering following the announcement of the adverse decision in the Northern Securities case. The market, although professional, was more cheerful in tone at the ending of the suspense, and the favorable crop reports and reported better demand for iron were factors in the improvement. London showed an increaseed disposition to bull American stocks. The Steel shares were the strong features on the better trade outlook, though the general list is higher throughout. The money market continued easy, although there was a slightly increased inquiry for time loans. Metropolitan Street Railway attracted much attention by reason of a break to 104¾ on unfavorable rumors regarding the local traction situation, but it afterwards rallied and closed at 111¾, being a net gain on the week's trading of 4⅞ points. The sales aggregated 65,200 shares. Brooklyn Rapid Transit, after receding to 39⅛, closed at 43⅞, which was the highest quotation of the week, and a net gain of 4⅜. All of the electric securities were also favorably affected by the better feeling in the market. General Electric was quite active, 3,000 shares having been sold. The range of prices was between 160, the lowest, and 167, the highest, the closing figure being 166—a net gain of 6½ points. Westinghouse also made a gain of 6 points, closing at 163, the number of shares changing hands being 5,100. Western Union remained practically steady as to prices, closing at 89⅜, thus netting ⅞-point increase. There was little done in the outside market. Fluctuations were irregular, Interborough Rapid Transit and Electric Boat being firm. Following are the closing quotations of March 22:

*Asked

THE MACKAY-BENNETT PROPERTIES:—An interesting analysis of the financial condition of the Mackay-Bennett telegraphic and cable properties is made as follows by the *Wall Street Journal:* "Applying the earnings of the Commercial Cable Company for the year 1903 to the securities of the proposed Mackay companies, the $1,708,526 surplus after charges equals 4 per cent. on the $30,000,000 cumulative preferred stock, and 1.6 per cent. on the $30,000,000 common. The stock of the Mackay companies, if the plan is successful, will be exchanged for the $15,000,000 stock of the Commercial Cable Company now outstanding at the rate of two shares of new preferred and two shares of new common for one share of Commercial Cable. As the latter is now paying 8 per cent. dividends, the full 4 per cent. required on the new preferred stock could be paid without increasing the present dividend requirements. The new common stock would represent the present individual earnings of Commercial Cable. It is possible that a larger earning capacity might be figured for the new common stock. In addition to the $500,000 reserve charged off from the surplus after dividends, Commercial Cable charged another reserve sum to operating expenses, under the item "land line repairs and reserve for reconstruction and extensions." This item last year amounted to $2,025,383, compared with $1,806,015 the previous year. The great growth in the business of the Commercial Cable Company in the last few years suggests possibilities for the common stock of the proposed company. In the last six years gross earnings have increased 65 per cent.

UNITED STATES TELEPHONE.—The financial report of the United States Telephone Company, of Cleveland, Ohio, made last week was exceedingly gratifying to the stockholders. One year ago the company had a deficit of $21,138, but the report last week shows the deficit entirely wiped out and a net balance of $15,972 on hand at the end of business for 1903. Plainly speaking, the company made $37,706.17 for the year 1903, instead of losing $21,138.32, as it did in 1902, and President Dickson says the profits for 1904 will be very much larger. It was the best report the stockholders had ever received from the company and the meeting had the flavor of a love feast. The company's balance sheet is as follows:

ASSETS.

	1903.	1902.
Property and plant	$4,054,887.30	$3,925,016.04
Material and supplies	30,651.93	53,073.47
Treasury stock	390,000.00	....
Treasury bonds	105,000.00	....
Current assets	99,926.83	86,202.27
Deferred assets	4,582.16	1,133.85
Total assets	$4,685,048.22	$4,065,425.73

LIABILITIES.

	1903.	1902.
Capital stock, common	$2,000,000.00	$2,000,000.00
Capital stock, preferred	500,000.00	....
Mortgage bonds	1,970,000.00	1,865,000.00
Current liabilities	187,817.16	215,201.00
Deferred liabilities	11,258.88	6,363.05
Total liabilities	$4,669,076.04	$4,086,564.05
Surplus	15,972.18	21,138.32
Total liabilities	$4,685,048.22	$4,065,425.73

The company's gross earnings for the year were $379,235.10, a gain of $76,838.85 over preceding year. Its net increase was $140,275.69, a gain of $17,165.48. The surplus was $37,706.17, a gain of $14,470.52. Deducting the $21,733.99 deficit, leaves a surplus of $15,972.18. The directors elected are H. A. Everett, F. S. Dickson, E. W. Moore, J. R. Sprankle, J. B. Hoge, J. W. Marsh, C. W. Wason, J. B. Hanna, R. Mahler. The officers are: F. S. Dickson, president; E. W Moore, vice-president; James B. Hoge, secretary; R. W. Judd, treasurer.

DIVIDENDS.—The American Telegraph & Telephone Company has declared the regular quarterly dividend of 1½ per cent. The dividend is payable April 15. Detroit United Railway directors have declared the regular quarterly dividend of 1 per cent., payable May 2. The Union Switch & Signal directors have declared the regular quarterly dividends of 2½ per cent. on the preferred and 2 per cent. on the common, payable April 10. United Gas Improvement, Philadelphia, has declared the regular quarterly dividend of 2 per cent., payable April 15. Bell Telephone, of Philadelphia, directors have declared a regular quarterly dividend of 1½ per cent., payable April 15. The General Electric Company has declared a dividend of 2 per cent. payable April 15, on the common stock. The Metropolitan Street Railway Company, New York City, has declared a regular quarterly dividend of 1¾ per cent. on the capital stock, payable April 15.

NEW BULLOCK COMPANY.—The incorporation papers of the Bullock Electric Manufacturing Company, of Norwood, Ohio, have been filed at Columbus, Ohio. The new company is incorporated with a capital stock of $500,000, the incorporators being Richard P. Ernst, Alfred C. Cassatt, Frank F. Cattle, James C. Marshall and John E. Shepard. It will be the leasing company of the present Bullock Company, which is now, through this leasing company, controlled by the Allis-Chalmers Company. The president of the new company is George Bullock and the vice-president Joseph S. Neave. Other details of this contemplated action were given in our issue of March 12.

CONNECTICUT MORTGAGE.—The Connecticut Railway & Lighting Company has filed a mortgage for $1,000,000 in favor of the Central Trust Company, of New York, to secure an equal amount of bonds.

NEW YORK-PHILADELPHIA TROLLEY.—The Middlesex & Somerset Traction Company, which has fifty miles of track in Middlesex and Somerset Counties, New Jersey, has been sold to the Public Service Corporation of New Jersey for $2,250,000. The Middlesex & Somerset Traction was owned by ex-Judge Gotfried Kreuger, of Newark; Andrew Radel, of Bridgeport, the heirs of the late John Radel and Edward H. Radel. The buying of the local trolley system completes the Public Service's through line from New York to Philadelphia. The corporation added very recently to its through line by purchasing the line from Camden to Trenton, and is now building a road from the terminus of the Camden road at Trenton to connect with the end of the Trenton fast line at the fair grounds. The Public Service closed the deal a short time ago for the right of way over the Trenton fast line, and, it is understood, will take over this road probably within the next thirty days.

FIGURES OF FRANCHISE TRUSTS.—In his recent work on the trusts, Mr. John Moody shows that there are 318 important industrial trusts in this country, controlling 5,288 plants, and having a total capitalization outstanding of $7,246,342,533. The eight leading franchise trusts are the American Bell Telephone, the Western Union Telegraph Company, the Commercial Cable Company, the Federal Telephone Company, the Consolidated Telephone Company, the International Telephone Company, the Interstate Telephone Company and the United Telephone & Telegraph Company. These control 136 plants and have a total capitalization of $629,700,500. There are also 103 leading gas, electric light and street railway consolidations, making a total of 111 important franchise trusts, controlling 1,336 plants, and having a total outstanding capitalization of $3,735,456,075.

Commercial Intelligence.

THE WEEK IN TRADE.—Reports from distributive centers still complain more or less of the backwardness of spring trade, which is generally attributed to the bad weather, yet there have been several favorable developments. Chief among these is the arrival of much-needed moisture in the southwestern wheat belt; the continued improvement in the iron and steel trade, and the decision of the bituminous coal miners not to strike against the proposed reduction of wages. The railway situation shows improvement, in that February made a slightly better comparison than January, an increase in gross receipts being indicated for the former month. Money continues easy, but collections are still classed as unsatisfactory at several points. The agricultural situation, though marred by the irregular condition in winter wheat, is on the whole very promising. An immense acreage will undoubtedly be planted in cotton in the South. In cotton liquidation has been a feature, induced by poor trade reports and slightly heavier receipts, the suspension of a large speculator resulting on Friday. A net loss of over 1½ cents per pound is shown on the week. In iron and steel large buying by leading interests has induced free purchasing by smaller concerns, hence advances are noted of 25 to 50 cents per ton on all grades of pig iron. Agricultural implement manufacturers are doing the best business in years. *Bradstreet's* reports 193 business failures during the week ending March 17, against 200 the week previous and 194 the corresponding week last year.

GOULDS PUMP CONTRACTS.—The Goulds Manufacturing Company, of Seneca Falls, N. Y., reports the following large recent contracts: Baltimore and Ohio Railroad Company, for its plant at Glenwood, Pa., three 13-inch x 12-inch Triplex power pumps with Westinghouse motors; Proctor & Gamble Co., Kansas City, Mo., 22 power pumps of various sizes for its new plant; E. J. DuPont Co., Penns Grove, N. J., 6 power pumps for the general water supply and distribution system; Indestructible Fibre Company, for Massena, N. Y., one 14-inch x 12-inch power pump, and one other of smaller size; Hurtig & Seamon's Music Hall, New York, a 500-gallon fire pump; Princess Theatre, New York, a 500-gallon fire pump; American Machinery and Export Company, one double-acting 14-inch x 16-inch Triplex power pump, for the water works at Vera Cruz; Brooklyn *Daily Eagle*, Brooklyn, N. Y., a 500-gallon fire pump, one Triplex deep open well pump, and also one house pump; Muller, MacLean & Co., New York, one Triplex power pump for water works plant, at Manila, P. I.; George A. Fuller Co., for the New York *Times* Building, New York, all Triplex power pumps on the specifications, with Crocker-Wheeler motors.

CUBAN LIGHTING AND TRACTION EQUIPMENT.—Contracts will be let very shortly for the construction and equipment of a large water power plant in Cuba, intended to develop current for lighting and traction in Cienfuegos and the towns of Caonao, Palmira, Harmiguera and Cruces, and for operating large sugar mills in the vicinity. The Cienfuegos, Palmira & Cruces Railroad & Electric Power Company will undertake the work. Mr. Bruno Diaz, a large Cuban cigar manufacturer, is president of the company. Mr. Cornelius C. Vermeule, 203 Broadway, is consulting engineer. The plant will be built at the Falls of Hababinalla, located about 30 miles from Cienfuegos. The available head is 480 ft. The initial capacity of the plant will be 6,000 hp. Four units of 1,500 hp will be put in. There will be about 40 miles of electric traction system constructed. About five miles of line will be built in Cienfuegos, which is without tramways of any description. The track will be standard gauge and 4,400 tons of T rails (70 pounds) will be ordered, with 4,100 trolley poles. Construction will be begun early in April and the entire system is expected to be in active operation inside of twelve months.

A 35,000-H.P. MEXICAN WATERPOWER PROJECT.—The construction of a hydraulic plant whose capacity is expected to be about 35,000 h.p. is contemplated in the State of Puebla by Mexican capitalists, who propose to supply light and power to various towns and industrial establishments in that part of the world. The necessary concession has been obtained from the Mexican Government authorities. The Falls of Flatlahuqui, on the Apulco River, will be utilized for furnishing the energy. These falls are reputed to be about 400 feet in height. Luis Fernandez Castillo, of Mexico City, is the concessionaire.

MEXICAN SUGAR FACTORY.—The Mexican Tropical Planters' Company, in which Boston and Kansas City capitalists are primarily interested, is about to let contracts for the construction of a large sugar factory on its 50,000-acre property known as the Columbia plantation, on the Coatzacoalcos River, Isthmus of Tehuantepec. It has not been fully determined yet whether or not the plant will be electrically operated. A large lighting equipment will, however, be installed. Mr. Louis Kunz is general manager at the plantation.

BULLOCK ORDERS.—The Bullock Electric Manufacturing Company of Cincinnati, Ohio, has just received an order from the Denver Gas and Electric Company, Denver, Colo., for one 1,500 kw 2,400 volt, 3-phase, 100 r.p.m., 60 cycle, fly wheel type generator. This machine is a duplicate of one they installed for this company about a year ago. The Denver Gas and Electric Company has also installed four 600 kw 3-phase, 2,400-volt alternators which makes a total of 6,000 kw in Bullock alternators installed.

THE AUTOMATIC ELECTRIC COMPANY announces that the Citizens' Telephone Company, of Columbus, Ohio, has increased the order placed with it some time ago. The original order called for complete Automatic equipment for 7,000 stations initial installation. The new order makes the number of stations to be installed in the beginning, 8,000. The Citizens' Company will build a new house for the Automatic Exchange, which will be designed specially for this type of equipment.

THE INDIANA RUBBER AND INSULATED WIRE COMPANY, Marion, Ind., has just finished sending out four orders to foreign countries. The first order was for 200,000 ft. of telephone wire or cable, which was shipped to Yokohama, Japan; the second for one ton of rubber tape, shipped to Alexandria, Egypt; the third one ton of tape to Berlin, Germany, and the fourth one ton of tape to Paris, France. Other foreign orders have been received and will be shipped soon.

BELL TELEPHONE OUTPUT.—The American Telephone & Telegraph makes the following instrument statement for the month ended February 29:

	1903.	1902.	1901.
Gross output	84,402	91,844	95,584
Returned	37,093	35,188	36,855
Net output	47,309	56,656	58,729
Total outstanding	3,880,616	3,296,527	2,637,355

BALL ENGINE CONTRACT.—On March 11 the Ball Engine Company, of Erie, Pa., made a shipment, composed of four cars, carrying a large 20 x 38 x 30 horizontal cross-compound side-crank engine, of their Corliss type, direct-connected to 400-kw alternator; alternator and wheels placed between the frames. This shipment went to the National Tube Company, Pittsburg, Pa.

EQUIPMENT WANTED IN ARGENTINA.—A large preserved meat factory is about to be built in the Argentine Republic, which will be lighted and largely operated by electricity. Alberto de Permentier, of Buenos Ayres, will be in charge of the construction. Interested parties writing him would do well if they used either the French or Spanish language.

STREET CAR CONSOLIDATION.—The J. G. Brill Company, the great street car builder, of Philadelphia, has secured control of the G. C. Kuhlman Street Car Manufacturing Company, of Cleveland, and will reorganize it.

THE EASTMAN KODAK COMPANY, of Rochester, N. Y., the well-known manufacturer of cameras, has purchased two 16 x 28 x 18 vertical cross compound engines of the Ball Engine Company, Erie, Pa.

General News.

THE TELEPHONE.

DENVER, COL.—The Wray Telephone Company has secured franchises in the eastern portion of the state for the extension of its system.

WASHINGTON, D. C.—The Kurtz International Telephone Company has been incorporated with a capital stock of $10,000,000. The incorporators are: J. W. Kurtz, J. A. Thompson, Harvey T. Winfield, Joseph A. Rath and Charles Fitts.

ALBION, ILL.—The Edwards County Mutual Telephone Company has been incorporated with a capital stock of $8000. Directors: W. J. Reid, T. B. Mitchell and others.

SALEM, ILL.—The Maron County Co-operative Telephone Company has been incorporated with a capital stock of $1000. The directors are: J. Herchberger, W. J. Martin and others.

HERMON, ILL.—The Hermon & St. Augustine Telephone Company has been incorporated with a capital stock of $1000. The directors are: W. A. Bogan, G. M. Brown and others.

DANVILLE, IND.—The Farmers' Co-operative Telephone Company has filed articles of incorporation. John F. Hardwick is president, and A. C. Underwood, secretary.

SOUTH BEND, IND.—The South Bend Home Telephone Company has purchased the property of the Electric Investment Company, of Mishawaka, paying therefor $14,000.

DANA, IND.—The Citizens' Mutual Telephone Company has incorporated. The capital stock is $6000. De Witt C. Keruse, Harry Bales and S. E. Scott are the incorporators.

TERHUNE, IND.—The Terhune Co-operative Telephone Company has filed articles of incorporation. Capital stock, $2000. Louis A. King, Albert Robison and Simon Cox are the directors.

ELBERFELD, IND.—The Elberfeld & Millersburg Telephone Company has filed articles of incorporation with the Secretary of State. The capital stock is $4500. Dr. L. Brown, Fred Kampe and Henry Menke are the directors.

SELMA, IND.—The members of the Selma Co-operative Telephone Company held a meeting last week and decided to purchase an exchange building and install a new switchboard, and otherwise improve and extend the plant.

TANGLEWOOD, IND.—The Tanglewood Telephone Association will construct a line to the corporation line of Versailles, where it will connect with the Spencer telephone system. This line will start with a large number of subscribers. Chas. Braley is president, and J. E. Waters, secretary.

WARREN, IND.—The Warren Home Telephone Company's plant has been sold to the Warren Telephone Company, recently incorporated with a capital stock of $25,000 for the purpose of taking over the old company's property. The plant will be improved and the lines extended throughout Huntington and Grant counties. W. Griffith heads the new company.

JONESBORO, IND.—A war has been declared on the Bell Telephone Company by the merchants of this city. Two companies have franchises to operate—the Bell and the Independent. The merchants grew tired of the dual systems, and adopted the Independent. The Bell Company's telephones have all been ordered out of places of business and a rule passed that any merchant in the future who uses a Bell telephone in his business or at home will be expelled from the association. The Bell Company now proposes to enter the mercantile business by establishing a large department store and low prices in Jonesboro.

INDIANAPOLIS, IND.—At a meeting of the stockholders of the New Telephone Company, on March 10, the following directors were elected: L. C. Walker, B. E. Parrott, J. W. Bowles, F. L. Holweg and I. D. Wiest. L. C. Walker was elected president to succeed S. P. Sheerin, who retired to become president of the Indianapolis Telephone Company. The lease of the properties of the New Telephone Company to the Indianapolis Telephone Company was authorized. The rapid growth of the business of the New Telephone Company made it necessary to raise additional capital in order to meet all the demands made for service. The report made to the stockholders showed that the gross earnings of the New Telephone Company during the year ending with February were $227,196, an increase over the previous year, after deducting operating expenses, depreciation, fixed charges and dividends, amounting to $177,410. The company now has a total surplus of $130,223. By the extensions to be made to the property by the Indianapolis Telephone Company, the earning capacity of the company will be increased nearly $250,000 a year, or nearly 20 per cent. gross on the $1,200,000 capitalization.

DURANT, I. T.—The Chickasaw Choctaw Telephone Company will erect an exchange here and extend its line to Bennington.

RICE, KAN.—The Hillsdale Telephone Company has been incorporated with a capital stock of $2500.

CLARENCE, MO.—A new telephone company is being organized here by farmers, to be known as the Independent Telephone Company. Frank Dorrell was elected president.

RALEIGH, N. C.—The Raleigh Telephone Company recently re-elected the present board of directors. The rumor of the sale of the company is stoutly denied. There are three companies in Raleigh.

ASHEVILLE, N. C.—At Asheville recently a number of citizens signed an agreement to use only the service of the Asheville Telephone Company, now sold out, and the question has arisen as to who is responsible for the low rates. The attorney of the new merger holds that the stockholders of the old company are responsible.

GREENSBORO, N. C.—An interesting fight is now on here over the attempt of the Southern Bell Telephone Company to raise its rates to "standard" rates, which the company claims is allowed it by the state corporation commission.

PAINESVILLE, OHIO.—A new telephone company has been organized here to install an exchange at Le Roy. W. M. Baker was elected president.

NORTH BENTON, OHIO.—The North Benton-Deersfield Telephone Company has increased its capital stock from $1000 to $15,000.

BRYAN, OHIO.—The Bryan Telephone Company has increased its capital stock from $40,000 to $75,000. W. W. Morrison is president.

LAKE, OHIO.—The Tri-County Telephone Company has been incorporated with a capital stock of $10,000. The directors are: N. B. Biddleman, M. M. Bauer and others.

NEWARK, OHIO.—The Newark Independent Telephone Company has now over 1400 connections. It has recently installed 70 new telephones and has orders for 25 more.

CALDWELL, OHIO.—The Farmers' Telephone Exchange Company has been incorporated with a capital stock of $10,000. The directors are: J. M. Harding, L. W. Wheeler and others.

FORT SUPPLY, OKLA.—The Fort Supply Telephone Company has been incorporated to construct a telephone from Beaver City to Gaery.

HARRISON, OKLA.—The Gotebo Telephone Company has been incorporated with a capital stock of $10,000. The directors are: H. Dalke, W. H. Kuda and others.

WILKESBARRE, PA.—A new telephone company is being organized here, with C. H. Randall as president.

PITTSBURG, PA.—The Pittsburg & Allegheny Telephone Company will extend its system to the south and west.

COLUMBIA, S. C.—The new telephone law in South Carolina, just passed by the state legislature, places all telephone companies under the supervision of the corporation commission. On account of alleged conflicting clauses, it is said that the bill will scarcely be effective. The commission has already applied to the attorney-general for an interpretation of the measure.

VOLGA, S. D.—The Dakota Central Telephone Company will extend its lines to Wentworth.

BROOKINGS, S. D.—The Thompson, Caldwell & Wilson Rural Telephone Company has been formed here. Materials have been ordered for the building of 60 miles of line.

DEADWOOD, S. D.—The Harrison Telephone Company has been succeeded in eastern South Dakota by the Home Telephone Company, recently organized to take over the system and business.

KNOXVILLE, TENN.—The People's Telephone & Telegraph Company has asked for a right to lay about one mile of underground conduit.

RIVES, TENN.—A new telephone company has been organized here by T. J. Bonner, B. J. Wade and others.

HUNTINGDON, TENN.—The Western Dixie Telephone Company has been organized at Vale, this county, with E. B. Simmons, president; Dr. Florence, vice-president, and A. N. Presson, secretary and treasurer. The company has lines in operation between Camden and Huntingdon and several subscribers at both places. It is the intention of the company to extend its service.

SAN ANTONIO, TEX.—The Southwestern Telegraph & Telephone Company will expend about $80,000 in extending and improving its system in this city.

NEW BRAUNFELS, TEX.—The Independent Commercial Telephone Company has applied to the City Council of New Braunfels for a franchise to install a telephone exchange here.

SAN ANTONIO, TEX.—Frank C. Smith, of San Antonio, president of the Commercial Telephone Company, announces that he has just purchased for his company the independent telephone exchanges at Austin, Taylor, Temple and Belton, and that he has leased from the Beaumont Northwestern Telephone Company the long distance lines and local exchanges belonging to that corporation. Mr. Smith denies the published report that he was acting for H. E. Huntington, of California, in making these purchases. He says that extensive improvements will be made to the acquired properties.

SALT LAKE CITY, UTAH.—It is stated by the management of the Independent Telephone Company that by May 1 its system will be in operation in Salt Lake and Ogden and that by that time the company will have expended $1,000,000 on construction work. Buildings in both cities are now almost ready for occupancy. A switchboard which will accommodate 12,000 connections is being installed here. The plans of the company include the invasion of Idaho and Montana within the next year.

LYNCHBURG, VA.—The Southern Bell Telephone Company has applied for a new franchise at Lynchburg, and a warm fight is expected. A minority report of the Council committees has been made asking for lower rates.

LENA, WIS.—A telephone company with a capital stock of $4000 has been organized here. It was promoted by A. W. Larson, of Wausaukee, and it will be known as the Farmers' & Merchants' Telephone Company.

MONROE, WIS.—Prominent farmers of Adams and Washington townships are organizing a telephone company for the purpose of building a line out through the towns. E. Holcomb, F. Hefty and others are interested.

VERA CRUZ, MEX.—The Government of the State of Vera Cruz has granted a concession to A. Espinosa, of Vera Cruz, for the establishment of a complete telephone system here.

CITY OF MEXICO, MEX.—The Department of Communications and Public Works of the Mexican Government has ordered the construction of an extensive system of telephone lines in the Yaqui district, State of Sonora. It is proposed to connect every town and hamlet in that district with telephone communication. This action is taken in order that the movement of troops in pursuit of Yaqui Indian outlaws may be expedited and also to help in the settlement and development of that rich region. The Secretary of Communications and Public Works, City of Mexico, can give information in regard to the proposed work.

Electric Light and Power.

CLANTON, ALA.—J. P. Van Derveer has a franchise for an electric light and power plant. The details will be ready in a short time.

MENDOCINO, CAL.—The Mendocino Electric Light & Power Company has been formed by A. Brown, of Mendocino, and others, with a capital of $25,000. They have purchased the electric light plant at Mendocino and will furnish light to the coast towns.

SANTA CRUZ, CAL.—The Big Creek Power Company, of Santa Cruz, contemplates erecting an additional generating station at Chittenden from which it can supply light and power to Watsonville, Gilroy and Hollister, if satisfactory terms can be obtained. A steam plant will also probably be constructed.

GLENWOOD SPRINGS, COL.—The Colorado Power & Irrigation Company is making preparations to begin immediate work on a plant at the Shoshone Falls, on the Grand River, near here, as soon as the weather conditions will permit. It is estimated that the plant will have a capacity of about 20,000 horse-power, which will be a sufficient supply for this city, Leadville and a number of adjacent mining towns.

WOODBURY, CONN.—An electric light plant will probably be erected this spring, at a cost of $15,000, by the local company. E. S. Boyd is secretary.

THOMASTON, CONN.—The Thomaston Electric Light Company has decided to construct a new plant in the spring. The plant was destroyed by fire last fall.

SANDPOINT, IDAHO.—The Sandpoint Water & Light Company has been incorporated, with a capital of $50,000, by J. D. Sherwood, Wm. G. Malloy and B. C. Riblet, of Spokane, Wash., and L. D. Farmen, of Sandpoint.

GEORGETOWN, ILL.—W. C. Dukes and Edw. Cooley have secured a franchise for an electric light plant.

HARMON, ILL.—The citizens and the Village Board are considering the advisability of constructing an electric light plant.

QUINCY, ILL.—The City Council has appointed a committee to investigate the feasibility of constructing conduits and placing all wires underground in the business district of the city, contemplating a general system over the entire city, to be owned and controlled by the city, users to lease the same. Address F. C. Hancock, city engineer.

NORTH VERNON, IND.—The Town Council is taking steps to enlarge and improve the electric light plant.

JASPER, IND.—It is reported that the Town Council is preparing to contract for the construction of an electric lighting and power plant.

HOPE, IND.—The Hope Canning Company has incorporated to install an electric plant to light its factory and also to sell light and power to the citizens of the town of Hope.

NEWHAVEN, IND.—Bids will be received April 5 by the Board of Town Trustees for furnishing material and constructing a complete electric light plant. H. H. Schnelker is chairman.

ANDERSON, IND.—The municipal electric light plant of this city has been enlarged to a capacity for a city of 50,000 inhabitants. The commissioners have announced that on April 1 a 30 per cent. reduction will be made in the rates for electric light service. The maximum rate at this time is 10 cents per kilowatt and the minimum is 6 cents.

ELKHART, IND.—The Elkhart Electric Company and the Home Electric Light & Power Company, of this city, have merged and filed amended articles of incorporation with the Secretary of State. The capital stock of the former company is $100,000 and of the latter company $50,000. The name of the merged or united company is the Elkhart Electric Company, and the capital stock is increased to $250,000. The operation of the new company will be carried on in Elkhart and Elkhart County.

CORNING, IA.—A receiver has been appointed for the Corning Electric Company on the application of the Hanover National Bank, of New York, and the First National Bank, of Corning, who are creditors of the company.

UNIONTOWN, KY.—G. F. Cecil, of Springfield, Ky., has purchased the electric light plant, and will make improvements to the same.

BALTIMORE, MD.—It is stated that the Maryland Telephone & Telegraph Company will enter the electric lighting and electric power field. This move will bring it into direct competition with the United Electric Light & Power Company, which has heretofore had a monopoly in this line. The Electrical Commission has granted a permit to the telephone company to enter the subway conduits with wires for furnishing electric lights and power. President Webb, of the telephone company, states that the company has purchased the plant of Mr. J. H. Purnell for immediate use, and that plans are being prepared for a larger plant, to cost about $1,000,000. The United Electric Light & Power Company has protested against the granting of such conduit privileges to the Maryland Company.

GRAND RAPIDS, MICH.—The question of enlarging and improving the electric light plant, at a cost of about $11,000, is under consideration by the Council.

GRAND RAPIDS, MICH.—The Cascade Electric Company, of Grand Rapids, has been organized to construct a power house on Thornapple River and transmit electricity to this city; capital, $15,000. The company proposes to construct a dam at Cascade, which will raise the river 22 feet, and furnish 1000 horse-power. E. C. Follmer is president and E. A. Stowe secretary.

SOUTH STILLWATER, MINN.—B. L. Hanks, Recorder, writes that the citizens have voted to issue bonds for an electric lighting plant.

HELENA, MONT.—The Bow Power Company, which was recently incorporated in South Dakota, is reported to have in contemplation the construction of a dam across the Missouri River below Helena and the generation of electric power to be conveyed to Helena, Butte, Anaconda and other points. About $750,000 will be expended.

SODUS, N. Y.—The Town Board has granted the Sodus Gas & Electric Company a franchise for an electric light plant.

PENN YAN, N. Y.—N. S. Dailey, Village Clerk, writes that it was voted March 15 to issue $35,000 bonds for the construction of an electric light plant.

ROCHESTER, N. Y.—As a result of negotiations between Mayor Cutler and the Rochester Gas & Electric Company, the poles and wires on Monroe Avenue in this city will be removed and the wires run through underground conduits.

NEW YORK, N. Y.—A bill has been introduced in the Assembly at Albany to confer additional powers upon the Board of Aldermen of New York City. One of the most important of these powers is the permission to establish, build or equip telegraph, telephone or other alarm system or systems of communication for the police and fire departments and for the construction of subways and pipe galleries for the purpose of containing wire tubes, conductors, sewer pipes, gas or water pipes, and for other similar purposes. This would affect the Empire Subway Company, which has a monopoly in its line in New York City now.

ASHEVILLE, N. C.—Bids are wanted April 1 for constructing an electric light plant. B. M. Lee is City Engineer.

OXFORD, N. C.—The Town Commissioners have granted Mr. Ehert, of Watertown, Conn., a franchise for water works and an electric light plant.

KINSTON, N. C.—Bids will be received by N. J. Rouse, Mayor, April 18, for constructing water works, a sewerage system and an electric light system.

HICKORY, N. C.—K. C. Menzies has been appointed temporary receiver of the Thornton Light & Power Company, of Hickory. The liabilities include a complete city lighting plant valued at about $25,000.

MINOT, N. D.—It is stated that an extensive addition may be built to the electric light plant this spring.

BEDFORD, OHIO.—The People's Electric Light Company, of this place, has passed into the hands of E. E. Mandeville and Edwards Robert, of Philadelphia, who will make considerable improvement in the machinery and equipment of the plant.

PITTSBURG, PA.—The Allegheny County Light Company has secured the contract for lighting the city for one year at $96 per 2000-cp arc lamp; and $35 for 50-cp incandescents.

COLUMBIA, TENN.—The Board of Aldermen has authorized the street commssion to investigate the question of constructing an electric light plant.

HEMPSTEAD, TEX.—An electric light plant is to be installed here. W. P. Lipscomb can give information.

SALT LAKE CITY, UTAH.—The Council is investigating charges against the Utah Light & Railway Company, which is accused of using inferior meters, unsatisfactory service, and charging the city and citizens for lighting which was not furnished. A similar investigation was made a short time ago by the Commercial Club, but no definite action was taken.

NEWPORT NEWS, VA.—The Consumers' Light, Heat & Power Company, of Newport News, has been placed in the hands of a receiver, J. A. Willett being appointed as such. T. T. Thompson, one of the largest stockholders, applied for the receivership, claiming that the business was not on a paying basis.

RICHLAND CENTER, WIS.—It is reported that the city will construct an electric light plant, at a cost of $20,000.

NEENAH, WIS.—The City Council has granted the Wisconsin Traction, Light, Heat & Power Company a 10-year franchise for lighting the city.

MARSHFIELD, WIS.—The City Council has come to an agreement with the Marshfield Water, Electric Light & Power Company, whereby the city is to buy the electric light and water plant at $150,400.

KEWAUNEE, WIS.—The question of issuing bonds for a new electric light plant and water works will be submitted to the people at the coming spring election. At the same time the question of municipal or private ownership will also be voted upon.

HAVANA, CUBA.—In consequence of the extension of the plans for the construction of the Cienfuegos, Palmira & Cruces Electric Power & Railway Company's system, bids for the work on the modified plans will be readvertised, to be received about June 15.

WHITBY, ONT.—Bids are wanted April 4 for $15,000 electric light and $50,000 water works bonds. Jos. White is Town Treasurer.

TORONTO, ONT.—The Electric Development Company, of Ontario, has made public some of its plans for transmitting power from Niagara Falls to Toronto. As a start, 50,000 horse-power will be transmitted. The company has a private right of way, and, in place of wooden poles to support the wires, galvanized steel towers will be used. These towers will be 400 feet apart and the west cross arm will be 45 feet high. There will be four circuits, so that in case of any accident to one of the circuits, three others will be available. The voltage on the line will be 60,000 volts. There will be a transformer house at Niagara Falls, at which the voltage will be stepped up, and another at Toronto where it will be stepped down to the voltage commercially in use. The works at Niagara are proceeding very rapidly and about 450 feet of the main tunnel has been excavated. The coffer dam is practically completed and the work on the wheel pit is progressing very rapidly. It is expected that the excavation of the pit will be completed about the first part of August next. The transformer houses will also be erected this season.

OTTAWA, ONT.—It is announced that one of the Canadian Pacific Railway Company's interesting changes, now in progress in the west, is the new stage reached in the work on the $500,000 power improvement to the company's facilities at Fort William, Ont. The motive, light and heating power is all to be changed to electricity. The work of installing the machinery in the new power house has just begun, and is proceeding apace. The power house is now complete with the exception of the machinery. The plant, when finished, will be capable of developing 3000 horse-power, which will be distributed over all the operations of the Canadian Pacific at Fort William, including the lighting systems, operation of the elevators, water works and machine shops.

THE ELECTRIC RAILWAY.

BIRMINGHAM, ALA.—The Birmingham Railway, Light & Power Company has bought a piece of property near its power house, so as to enlarge the plant. Several new boilers, a 60-cycle, three-phase, 2300-volt alternator and a new direct-current, 1600-kw, 575-volt generator will be installed.

OAKLAND, CAL.—The San Francisco, Oakland & San Jose Railroad Company, operating the Key Route, is preparing to erect new shops and enlarge the power station capacity. Eight-car trains are frequently operated on this line.

DENVER, COL.—General Manager C. W. Sells, of the Manitou & Pike's Peak Cog Road, announces that after this year the road will be operated by electricity. The work of changing the motive power from steam to electricity will cost approximately $200,000.

LOVELAND, COL.—It is said that W. A. Riley, who constructed the Loveland-Estes Park road, has under consideration a plan to build an electric railway on the road. Mr. Riley, it seems, built the road for the county at a cost of $18,000, and it is said that they would grant him a franchise over it for a like amount.

GLENWOOD SPRINGS, COL.—Albert C. Johnson, who says he represents considerable southern capital, has been here looking into the feasibility of building an electric railway from Glenwood Springs to Mt. Sopris, 12 miles south, and has incidentally looked into the practicability of building a similar line over the mountains to Trapper's Lake, about 25 miles north.

LEADVILLE, COL.—The Leadville-Denver Mining, Tunnel & Tramway Company has voted to issue $500,000 worth of bonds for the purpose of building an electric railway from Leadville 6 miles to a point where a tunnel will pierce the mountains for half a mile. This new electric road will cost, with its equipments, $260,000, and will be a connecting line for the steam railroads between Denver and Leadville. It will cut down the distance between the two points mentioned 175 miles by the Denver & Rio Grande Railroad and 40 miles by the Colorado & Southern Railroad. The new line will be equipped for carrying both freight and passengers. The officers of the company are: James A. Shinn, president; Alfred C. Phelps, vice-president; Byron Tifft, secretary. The company is incorporated for $2,000,000.

HARTFORD, CONN.—The board of directors of the Danbury & Harlem Traction Company has elected D. E. Leowe, of Danbury, president; Stephen B. Quick, of North Salem, vice-president; J. N. Cronley, of New York, secretary; Phillip Simon, of Danbury, treasurer. Technical difficulties arising from a transfer of control of the corporation resulted in a cessation of construction work, but it is expected that operations will be resumed this spring.

HILLSBORO, ILL.—Application for incorporation has been made to the Secretary of State for the Hillsboro Electric Railway Company.

CHICAGO, ILL.—Fire recently destroyed the Blue Island Avenue barns of the Union Traction Company. Six hundred cars burned and the building was totally destroyed. The loss will be about $300,000.

SPRINGFIELD, ILL.—Articles of incorporation for the Springfield, Lincoln, Bloomington, Pekin & Peoria Electric Railway Company, with a capital stock of $50,000, have been filed. The principal offices will be located at Bloomington. The incorporators are: Lafayette Funk, of Shirley; D. W. Hart, of Lincoln; A. G. Kingman, of Peoria; J. F. Prather, of Williamsville, and Logan Hay, of Springfield. The board of directors is composed of S. E. Prather, Lafayette Funk, F. W. Aldrich, W. H. Evans, A. G. Kingman and J. W. Hoblit.

INDIANAPOLIS, IND.—The French Lick & West Baden Electric Railway Company has increased its capital stock to $50,000.

COVINGTON, IND.—The Fountain & Warren Traction Company, which plans to build an interurban railroad from Covington east to Lafayette and west to Danville, Ill., is stated to have financed its project, to have made all arrangements for building the line and to have awarded equipment contracts.

KOKOMO, IND.—New officers and directors have been chosen at a meeting of the Kokomo, Marion & Western Traction Company. They are as follows: George J. Marott, of Indianapolis, president; L. J. Kirkpatrick, of Kokomo, vice-president; F. C. McReynolds, of Kokomo, secretary and treasurer; Lee Hall, of Marion, superintendent of construction. It has been decided to proceed at once to extend the line as far east as Bluffton and west to Lafayette and Lebanon the coming season.

INDIANAPOLIS, IND.—The Interstate Traction Railway Company, composed of Ohio capitalists, has filed articles of incorporation with the Secretary of State. The company will build between Dayton, Ohio, and Indianapolis. The road will be 120 miles long. The capital stock of the concern is $50,000. The principal offices of the company will be at Liberty, Ind. The incorporators are: John D. Boroff and W. H. Heinz, of Dayton; E. R. Phillips, of New Carlisle, O., and B. A. Landis, of Camden, O.

LANSING, MICH.—The Indiana & Michigan Electric Company is reported to have been organized in Trenton, N. J., with a capital stock of $2,000,000, for the purpose of furnishing light and power and operating electric railway lines in the states named. The incorporators of the company are: G. W. Flaacke, Jr., H. Hobart Porter, Jr., and Francis Blossom, of Jersey City.

GRAND RAPIDS, MICH.—The Grand Rapids & Ionia Railway Company, Ionia & Owosso Railway Company and the Jackson & Lansing Railway Company are all owned and controlled by the same interests. They will build lines from Grand Rapids to Ionia, from Ionia to Owosso and from Jackson to Lansing, 33 miles, 45 miles and 37 miles long, respectively. No contracts for building any of the lines have been let. The office address of the companies is 1114-17 Majestic Building, Detroit.

LANSING, MICH.—The Lansing & Suburban Traction Company has been incorporated under the street railway law of Michigan, with a capital stock of $1,000,000, for the purpose of taking over the property of the Lansing City Electric Railway, the Lansing, St. Johns & St. Louis Railway, and building a proposed extension from Lansing to Pine Lake, a resort about 10 miles from the city of Lansing. The stockholders of the company are: Nelson Miles and Myron W. Mills, of Maysville; George G. Moore, of Port Huron, and James H. Elliott, of Lansing. James H. Elliott, the present manager of the Lansing Street Railway Company, will, it is understood, be the managing director of the new company.

MAGNOLIA, MISS.—S. E. Shilling and associates are having a line surveyed from Magnolia, through Fernwood, McComb City and Summit, 12 miles, with a view of constructing an electric railway.

JACKSON, MISS.—The Senate has passed the House "Jim Crow" street car bill, which provides that street car companies shall provide separate compartments for whites and blacks.

ST. JOSEPH, MO.—Mrs. Anna Butler, of Des Moines, Ia., representing New York and Cleveland capitalists, who are promoting an electric railway between St. Joseph and Kansas City, and also a new line north of St. Joseph toward the Iowa line, is planning to go before the local Council in behalf of the interests she represents with an application for a street railway franchise.

OMAHA, NEB.—The Omaha & Council Bluffs Street Railway Company plans to dispose of $2,000,000 of bonds when market conditions are favorable, so as to pay for improvements to the property last year and to provide for improvements to be made this year. A new power house, to cost about $500,000, is now under construction, and a number of important extensions of the company's lines have recently been made. The plans of this year provide for carrying out the general improvements begun last year and for building a number of important new lines.

MORRISTOWN, N. J.—The Morris County Traction Company plans to begin the construction of its proposed road Aug. 1. All contracts for building the line and furnishing the equipment have been let. The line will run from Dover to Morristown, Summit and Elizabeth. Power will be hired. Robert D. Foote is president; F. H. Alleman, secretary and manager.

NEW YORK, N. Y.—The New York City Railway Company, of Manhattan, and the Brooklyn Rapid Transit Company, have agreed to co-operate in operating cars over the new Williamsburg bridge. The effect of the agreement is that the two companies will each use two of the six tracks on the bridge for the carrying of their passengers to the opposite bridge terminal, while the remaining two tracks will be used for the running of shuttle bridge cars. The power for these shuttle cars will be supplied by the two companies. Terms satisfacotry to the two companies are yet to be fixed by the Bridge Commission.

NEW YORK, N. Y.—In a circular issued by the Municipal Art Society still another plan for the relief of the traffic congestion on the Brooklyn Bridge is suggested. The idea is to make a loop on Manhattan Island for the tracks now running over the bridge. It is suggested that the north or Manhattan tracks be continued by a curve to the north in descending to a subway at Reade and Elm Streets, and thence passed under the present subway and across under Reade Street to West Street, under West to Liberty, under Liberty to Broadway, under the subway in Broadway, and continuing east to Nassau, under Nassau Street and the east side of Park Row back to and over the Brooklyn Bridge as its southern track. New stations are proposed at Reade Street and Broadway, Reade Street and West Broadway, West and Warren, West and Fulton, West and Liberty and Liberty and Nassau Streets.

OKLAHOMA CITY, O. T.—The latest in interurban electric railway projects here is a plan to build a line to connect Oklahoma City, Lawton, Norman, Shawnee, El Reno and Chickasha. Pennsylvania capitalists, among whom are H. E. Ahrens, of Reading, and J. H. McDonald, of Reedsville, are said to be interested.

KANE, PA.—Another effort is being made to organize a company to build an electric railway connecting Kane, Johnsonburg, Ridgway and St. Mary's.

PUNXSUTAWNEY, PA.—The Jefferson Traction Company has completed securing right of way for an extension of the Punxsutawney & Reynoldsville line from the latter place to Sykesville, a distance of about 6 miles. Work on the extension will be begun as soon as the weather permits. The Jefferson Company has an agreement with the DuBois Traction Company to build a line from that place, which will connect with the Reynoldsville & Sykesville line at the latter place. The DuBois Company will also begin the work of constructing this spring. The Sykesville and DuBois division will be about 9 miles in length.

POWNAL, VT.—The Selectmen of Pownal have granted a franchise to the Bennington & North Adams Street Railway Company for the construction of a line through that town. The company desires to build from Williamstown through the town of Pownal to the Bennington line.

RICHMOND, VA.—The Seaboard Traction Company has been chartered, with a capital of $250,000, to build an electric railway from Richmond to Portsmouth. The principal offices will be at Suffolk, Va. The officers are as follows: L. R. Britt, president; W. H. Robinson, of Norfolk, first vice-president; W. D. Southall, treasurer; Geo. H. Lewis, of Norfolk, general manager; Lee Britt, of Suffolk, secretary and auditor. The line will open a quick outlet for the great trucking interests of eastern Virginia. Power houses will be erected, and part of the power may be secured from the new Appomattox River plant at Petersburg. The charter provides that work shall begin at once. The capital stock may be raised to $800,000.

CHIPPEWA FALLS, WIS.—The Chippewa Valley Electric Railway Company has mortgaged its property for $750,000 to the Security Trust Company, Camden, N. J. Of the sum, $250,000 will be used for building new lines.

MONTREAL, QUE.—Notice is given that application will be made to the Parliament of Canada at the next session for an act to incorporate the Canadian Traction & Power Company, with power to construct a railway from a point in or near the city of Montreal to a point in or near the city of Ottawa, with branch lines. Louis Boyer, of Montreal, is solicitor for the applicants.

NEW INDUSTRIAL COMPANIES.

THE CITIZENS' ELECTRIC COMPANY, of Amsterdam, N. Y., has been incorporated; capital, $50,000. Directors: W. W. Dickson, M. G. Walsh and G. C. Stewart, Amsterdam.

THE NEW YORK & PENNSYLVANIA RAILWAY (reorganized) has been incorporated; capital, $570,000. Directors: F. A. Cobb and Howard Cobb, Ithaca, and H. M. Cook, Hornellsville.

THE EDGERTON ELECTRIC MOTOR MANUFACTURING COMPANY, of Philadelphia, has changed its name to Dialt Motor Company and increased its capital stock from $300,000 to $1,250,000.

THE SWITCHBOARD MANUFACTURING COMPANY, of New York, has been incorporated with a capital stock of $15,000. The directors are: August Schraam, Louis Freund and Ernst Ohnell.

THE STUDEBAKER AUTOMOBILE COMPANY, South Bend, Ind., has filed articles of incorporation with the Secretary of State. The capital stock is $100,000. The company will manufacture and sell automobiles.

THE REPUBLIC BUILDING COMPANY has been organized in Cleveland, O., with a capital stock of $500,000. The purpose of the company is to erect a 10-story power building for light manufacturing concerns.

THE ROBBINS ELECTRIC COMPANY has been incorporated at Washington, D. C., with a capital stock of $150,000, the names of the incorporators being H. Clay Campbell, Charles Embrey and Ralph E. Campbell.

THE RIO DE JANEIRO TRAMWAY, LIGHT & POWER COMPANY has been incorporated in Jersey City; capital, $200,000. Incorporators: Horace S. Gould, Otho S. Lee, Edgar E. McWhinnery and Charles A. McCredy.

THE GLOBE ELECTRIC COMPANY has filed incorporation papers at Camden, N. J. Its purpose is to deal in and sell electrical machinery. The capital is $100,000. The incorporators are Henry S. Riebenack, W. C. L. Eglin and James E. Hays.

THE WARREN & JAMESTOWN STREET RAILROAD COMPANY (merger and reorganization) has been formed at Jamestown, N. Y.; capital, $200,000. Directors: David M. Siggins and H. M. Preston, Warren, Pa., and C. H. Clifford, Jamestown.

THE ELECTRIC SUPPLY COMPANY has been chartered at Savannah, Ga., with a capital stock of $25,000, with the privilege of increasing to $100,000. The purpose of the company is to carry on a general electrical supply and repair business with headquarters at Savannah.

THE ELECTRIC BLOCK RAILWAY SIGNAL CORPORATION has filed incorporation papers at Augusta, Me., with a capital stock of $10,000. The officers are: President, F. C. Robinson, Farmington, Me.; treasurer, W. H. Cook, Farmington, Me.; director, E. H. Whitney, Farmington, Me.

THE EASTERN ILLINOIS TRACTION COMPANY has been incorporated at Mattoon, Ill., with $5000 capital. The road will run from Mattoon, Coles County, to Champaign, Champaign County. E. A. Potter, of the American Trust & Savings Bank, Chicago, is one of the incorporators.

THE INDIANA & MICHIGAN ELECTRIC COMPANY has been incorporated in Jersey City; capital, $2,000,000. Incorporators: George W. Flaack, Jr., H. Hobart Porter, Francis Blossom, Herman L. Crawford, Lyman J. Dwyer, Frederick P. Delafield, Frederick W. Longfellow, Henry C. Colwell and Harold S. McKee.

LEGAL.

TO REORGANIZE.—The business of Robert L. McOuat, wholesale dealer in electrical supplies at 125 S. Meridian Street, Indianapolis, Ind., has been turned over to A. F. Potts, as trustee, for reorganization. The trustee will continue the business until the new company takes charge.

LANGE LAMP SOCKET PATENT SUSTAINED.—The Lange patent on the present method of fastening together the cap, shell and insulation of incandescent sockets has been sustained in a decision of the United States Circuit Court of Appeals of the Third Circuit. The present owners of the Lange patent are the Bryant Electric Company.

THE W. H. SMITH COMPANY, Indianapolis, Ind., dealer in electrical supplies and power equipment, has been placed in the hands of a receiver—Mr. George B. Elliott—on the petition of the Gillmore Electric Company, of South Boston, Mass. The prolonged illness of President W. H. Smith is given as the reason for the concern's embarrassment.

COMPETING TELEPHONE LINES.—The Supreme Court of Iowa has held that where neither of two telephone companies had the exclusive right to string its wires along a particular side of a street or highway, it was proper for the court to require that their wires should be constructed a sufficient distance fom each other so that the use of one would not unreasonably interfere with the use of the other.

INDIANAPOLIS, IND.—A suit has been filed here asking for a receiver for the Edwards Railroad & Electric Light Company. The company was incorporated under the laws of Indiana and has its business office in Chicago and its factory in Ohio. The company was organized to manufacture and repair steam engines, electric dynamos, electric arc lights, etc. The complaint charges that the company has violated the corporation laws of the three States; also mismanagement.

ERECTING POLE LINE.—The Supreme Court of Pennsylvania, in the suit of the city of New Castle, Pa., vs. the Central District and Printing Telegraph Company, decided as follows: 1. A city may provide by reasonable regulations for the use of its streets by a telegraph or telephone company. 2. An ordinance that a telephone company may apply to the council to have its poles located, and that the council may designate the location of each pole, or authorize the street committee or the city engineer to make the location, is not invalid, as preventing the company from erecting poles in any street in the city, or impairing its right to so do. 3. A city ordinance required that telephone poles should be located under the approval of the city engineer, and under his supervision. A mere verbal approval by the engineer of a general plan showing the place where the poles were to be erected does not authorize their erection at the points designated without further supervision by the city engineer.

LEBANON, IND.—Judge Artman, of the Boone Circuit Court, has rendered a decision of great importance to the telephone men in Indiana. There are two telephone companies in Thorntown, and one in Lebanon. The cities are 16 miles apart. The Lebanon Telephone Company entered into a contract with the Thorntown Independent Company whereby the latter was to be granted exclusive service between Thorntown and Lebanon. Then the Thorntown Co-operative Company applied for admission to the Lebanon Company's switchboard, but was refused because of the contract with the other company. The Co-operative Company then applied for a writ of mandate to compel the Lebanon Company to admit it to its switchboard, alleging that the Lebanon Company was a common carrier and could not discriminate against companies. In making up the issues of the case two months ago, Judge Artman held that if the allegations in the complaint were true the Lebanon Company was a common carrier, and as such would be bound to grant connection to all companies seeking admission. However, the case went to treat on the question of facts, and after taking the matter under advisement for two months Judge Artman rendered a special finding holding that the allegations in the complaint were not sustained; that it had not been established that the Lebanon Telephone Company was a common carrier, and for these reasons his decision must be for the defendant and the petition dismissed. The case will be appealed to the Supreme Court.

DUTY AS TO BROKEN WIRE. On the appeal in the case of a man who had been killed by contact with a broken wire of an electric light company in a storm, the Supreme Court of Louisiana has ruled as follows: A wire of an electrical company, detached from the poles and lying in the streets of a town, is, of course, out of place, and those having control of it and charged with the legal duty of taking due care of it have the burden of accounting for its being found in that condition and situation (Maus vs. Broderick, 25 South. 977, 51 La. Ann. 1153), and to show that it was not due to its negligence. It is the absolute duty of an electric light company conveying electricity by overhead wires strung through the streets of a city to keep its wires constantly insulated so as to be prepared to guard against the effect of objects coming in contact with them regardless of the facts and causes which may bring about the contact. The fact that a telephone company may have strung its wires above those of the electric light company already in position, and should have taken no steps to guard against the coming in contact of the wires of the two companies at the crossing points, and that in stringing its wires it did so negligently and loosely that one of its wires fell, in a storm, upon an uninsulated wire below, causing it to burn and fall on the street, is no excuse to the electric company in not having performed its own duty of additional and special precautions in the premises. A fault on the part of the telephone company did not relieve it from the consequence of its own fault. The falling of the telephone wire on the wire below would have been attended with no disaster but for the uninsulated condition of the latter, and that condition is to be attributed as the proximate cause of the death of the husband and father of the plaintiffs.

ORDINANCES FOR LIGHTING.—In an action by J. Le Feber, et al, against the Northwestern Heat, Light & Power Company, et al, as to a franchise granted, the Supreme Court of Wisconsin has reversed a judgment for the defendants. The place was West Allis, Wis., and the ordinance was assailed as unreasonable. The Supreme Court's views are: 1. Though the discretion of municipal corporations in the exercise of the powers conferred upon them by the Legislature will be given a broad scope and accorded great deference by the courts, nevertheless that power must be exercisd for public purposes and, if an ordinance be so remote from such purposes that no relation thereto can be discovered, it will be held unauthorized and invalid. 2. A village ordinance granted to a certain company the exclusive right to furnish lights for the city and its inhabitants for a period of 30 years, and if, within a period of four months immediately preceding the expiration of the 30 years, the city should fail to make arrangements to purchase the plant, then for an additional period of 20 years. The village was located within a few miles of a large city, and had come into existence because of the location there of large manufacturing establishments. The electric street car lines from the city had been extended to the village at the time the ordinance was passed. The prices which the ordinance authorized the company to charge for the various kinds of light which it was to furnish were from 30 to 75 per cent. in excess of those paid elsewhere under similar circumstances, the greatest excess being upon the only variety of lights which the company could be compelled to furnish. The contract contained no provisions by which the village could compel the company to extend its gas mains or electric wires or to furnish any other than gasoline lights. It was provided that the company should commence active work within five months from the time the ordinance was accepted, but there was no provision as to when such work should be completed. The village had sufficient inhabitants to make it a city, though the fact could not be established until a State census was taken; and Rev. St. 1898, Sec. 925-52, subd. 34, provides that cities shall not make lighting contracts for a longer period than 10 years. Held, that the ordinance was void for unreasonableness. 3. The grounds of the invalidity of the ordinance so permeated the whole, and were so interdependent, that the unreasonable and illegal features could not be eliminated so as to allow the remainder to stand. 4. The fact that a village ordinance has been submitted to a popular vote and assented to by a majority of the electors of the village does not prevent it from being held void as unreasonable.

PERSONAL.

ARTHUR WARREN.

MR. ARTHUR WARREN.—In enlarging extensively its sphere of operations, the Allis-Chalmers Company has found it desirable to increase the scope of its Publishing Department, and it has been fortunate enough to secure the services of Mr. Arthur Warren, whose work in the field of technical journalism and whose success as what one may perhaps call a "publicity promoter" is too well known to everyone in the electrical field to need dwelling upon. Mr. Warren is a Bostonian with remarkable qualifications for the work to which he has of late devoted himself. Coming of a family of considerable mechanical aptitude and distinction, he prepared himself for the technical side of his work by actual machine shop practice. After this he began to travel, and while traveling wrote about things which he saw. The transition to journalism was easy, and in 1883 Mr. Warren joined the staff of the *Boston Herald*, then as now one of the most influential journals in the country. With this newspaper he remained for 14 years, becoming its leading special article writer and discussing not only economic topics, but venturing into the fields of biography and of dramatic and literary criticism. Meantime Mr. Warren took up other editorial work and was assistant editor of the *Beacon*, a well-known Boston weekly, and from 1886 to 1888 editor of the *Boston Home Journal*. In December, 1888, Mr. Warren was sent abroad by the *Boston Herald* as its London correspondent, in which capacity he served it most efficiently for some nine years, besides writing for a number of other American and British publications. His London home, which he still retains, was thus for many years a charming center of social and literary intercourse, in which many famous Americans and Europeans participated. In November, 1897, Mr. Warren returned to the United States at the invitation of Mr. George Westinghouse, a man quick to recognize the talent suited to carry out important new plans; and he immediately proceeded to organize the Westinghouse Publication Bureau, whose record of solid achievement in the way of publicity of the best kind as to articles, pamphlets, advertising and the diplomatic aspects, has certainly never been surpassed. In February of this year, his work in that connection both in this country and in England being practically completed along the original lines laid down, Mr. Warren resigned. He has been actively engaged since then in this city on literary work of all kinds for the leading magazines and newspapers, and had planned to sail for Europe on March 12, when he was invited by the executive of the Allis-Chalmers Company to become manager of publicity for that corporation under its new regime. The field of available talent had been thoroughly looked over, and it was felt that by training and experience Mr. Warren was the man for the very important post. Mr. Warren has accepted the offer, and has already taken up his new duties. While he may himself entertain regrets at not following up the purely literary work offered him in really embarrassing abundance, it is a matter of congratulation that he will devote his time and energies to the publicity side of one of the greatest and most comprehensive mechanical enterprises in the United States.

MR. M. L. MORA, of the General Electric Company, is in Cuba. He is expected back in a week or ten days.

MR. W. K. PALMER, the well-known consulting mechanical and electrical engineer in Kansas City, has moved his office to 402 Lyceum Building.

MR. JAMES BLAKE CAHOON, electrical and hydraulic engineer, has removed his offices to suite 1725-6, in the new building, 42 Broadway, New York.

MR. W. MURRAY CRANE has been elected a member of the board of the Western Telephone & Telegraph Company, to succeed the late J. Malcolm Forbes.

DR. S. S. WHEELER, president of the Crocker-Wheeler Company of Ampere, N. J., has sailed this week for Europe, and will be gone for some six weeks on the trip.

MR. H. K. WOOD, of the Hartford Time Switch Company, Hartford, Conn., was in New York for a day or two last week. On this occasion he arranged with F. H. Lovell & Co. to represent his switch and his company in New York City.

MR. T. A. EDISON.—The report has been so widely circulated that he was going to London in May, that Mr. Edison, now on his plantation in Florida, has felt compelled to make a flat contradiction of the rumor sent over by cable.

MR. HAROLD D. PATTERSON, formerly superintendent for Mr. Max Osterberg, has become connected with the United States Battery Company of New Rochelle, N. Y., in the capacity of electrical engineer, and has assumed his new duties.

MR. H. C. TUNNELL.—The Lincoln Electric Company, of Cleveland, O., announces that its New York representative is Mr. H. C. Tunnell, 65 Bank Street, Newark, N. J. The Lincoln Company has manufactured dynamos and motors for some years past.

MR. CORNELIUS C. VERMEULE, 203 Broadway, is back from Cuba, where he recently went in connection with the construction of the Cienfuegos, Palmira and Crucas Electric Power and Railway Company, of which concern he is the consulting engineer.

MR. D. J. BURNS, of the Ward Leonard Electric Company, Bronxville, New York, recently arrived in New York after an extensive trip in the West and Southwest. He reports that business conditions in general are good, while they are excellent with respect to the affairs of his company.

MR. G. H. MUNROE.—New York newspaper men and special representatives of the leading newspapers out of the city were entertained at dinner at the Waldorf-Astoria on March 14 by George H. Munroe, of the banking firm of Munroe & Munroe, who managed the underwriting of the Marconi company.

MR. W. S. TURNER, manager and engineer at Auckland, New Zealand, for the British firm of J. G. White & Co., for some time past, has returned to New York after staying also some months in London. While in New Zealand Mr. Turner superintended the construction of a fine street railway system for Auckland.

MR. CHARLES M. SWIFT, of Detroit, Mich., who is president of the Manila Railway, Light and Power Company, has gone on a trip to the Philippines to inspect the progress made in the construction of the company's system, the contract for which is being carried out by J. G. White & Co., of New York City.

MARKS—VAN PRAAG.—The marriage took place on March 15, of Mr. Louis Benedict Marks, of New York City, to Miss Sadie Van Praag, daughter of Mr. and Mrs. Leon A. Van Praag. The happy pair are now on their honeymoon. Since perfecting his work on the enclosed arc, Mr. Marks has been practicing as a consulting electrical engineer.

MR. RAY D. LILLIBRIDGE, who has been making a two months' trip through the West, visiting particularly the power transmission plants of the Pacific coast and Colorado, has just returned home to New York much benefitted by the change. In behalf of the Stanley Company Mr. Lillibridge has prepared and issued some most interesting technical literature as to power transmission plants on the Pacific Slope.

MR. ARVID REUTERDAHL is the author of two recent pamphlets, one of which is entitled "The Radioactive Atom," and the other "Electrolysis According to the Energonic Hypothesis." In the former of these Mr. Reuterdahl develops a new and radical theory of the constitution of matter and the role of energy. The latter presents criticisms against the accepted theory of electrolytic dissociation, and offers a substitute based upon a new bypothesis concerning the ultimate constitution of matter.

MR. J. H. HALLBERG has severed his connection with the Cincinnati Gas & Electric Company. Less than a year ago, he took charge of the Cincinnati system, one of the largest in Ohio and in the country, as general superintendent of the electrical department. He reorganized the station, increased the output of the plant, straightened out the system of feeders, increased the economy of operation and obtained the respect and admiration of all who came in contact with him, for his ability and honesty of purpose. At the last meeting of the Cincinnati chapter of the American Institute of Electrical Engineers, he was elected vice-chairman. Mr. Hallberg, who resigned last week, intends to leave Cincinnati, it is said.

MR. C. O. BAKER, JR., for so many years the popular and efficient master of transportation for the National Electric Light Association, has resigned from that position. Mr. Baker expects to be in Europe at the time of the Boston meeting, to be held May 24-27 next, and feels that he should not continue in the office unless he can personally attend to the duties connected with it. President Edgar has appointed Mr. George F. Porter to succeed Mr. Baker. Mr. Porter had charge of transportation matters before he became secretary of the association, and organized special trains for the Philadelphia convention, February, 1887, the Chicago convention, February, 1889, and the Kansas City meeting, February, 1890. During the ten years that he was secretary, he had more or less to do with transportation arrangements, and being very popular with the railroad people as well as with the delegates to conventions, his appointment is another instance of President Edgar's good judgment in the selection of willing men to work for the welfare of the association.

MR. PHILETUS W. GATES and Mr. Henry W. Hoyt, respectively general superintendent and second vice-president of Allis-Chalmers Company, are about to retire from active participation in the management of that company. Mr. Gates was president and Mr. Hoyt secretary and general manager of Gates Iron Works for fifteen years prior to the incorporation of Allis-Chalmers Company in 1901. They have been prominently connected with the manufacturing interests of Chicago and have taken an active part in all of the manufacturers' associations. The late P. W. Gates (father of Philetus W. Gates) was the pioneer manufacturer of Chicago and the region west of the Alleghenies, having established his business in 1842. From 1861 to 1871, the Eagle Works Manufacturing Company, of which he was president, employed about one thousand men, and in those days was a noteworthy industry. In 1871 the Eagle Works Manufacturing Company went out of existence and from it were organized Gates Iron Works and Fraser & Chalmers, each taking a portion of the business. Both of these companies in turn were taken over by Allis-Chalmers Company in 1901. Messrs. Hoyt and Gates, after a well-earned vacation spent in traveling, will re-engage in business in Chicago.

COMMANDER B. A. FISKE, U. S. N.—In the first edition of the "Text Book of Ordnance and Gunnery," prepared by Lieut. Commander W. F. Fullam and Lieut. T. C. Hart, U. S. N., for the use of midshipmen at the Naval Academy, a very brief reference was made to the history of the telescope sight, and the first of a series of patents, made by Lieut. (now Commander) Bradley A. Fiske, U. S. N., in 1890, was mentioned. Commander Fiske is widely known in electrical circles. It is with a view to giving well deserved credit to Commander Fiske for originating, and for persisting in the advocacy of the telescope sight for naval guns, that the following note (addendum) has now been inserted in the "Text Book of Ordnance and Gunnery:" "Addendum: Par. 7, page 233, Text Book of Ordnance and Gunnery, 1903, 'The Telescope Sight.' It is but just to Lieutenant (now Commander) Fiske to state that to him belongs the credit for first demonstrating the fundamental advantages of this type of sight over all kinds of open sights for naval use. Following the patent of 1890, he obtained four patents between 1891 and 1895 in which he provided for attaching the telescope to the gun sleeve and for making compensation for drift and speed; and he proved the practicability of using this form of sight for naval guns by official tests at sea during the years 1892, 1893 and 1894. The Bureau of Ordnance of the U. S. Navy was the first to recognize the value of this invention; and it is plain that the essential principles of the latest type of naval telescope sight do not differ from those covered by Lieutenant Fiske's patents, which were embodied in his original instruments."

EDUCATIONAL.

DELAWARE COLLEGE, DEL.—The Department of Mechanical and Electrical Engineering has during the past few weeks added to its equipment in the dynamo laboratory some useful apparatus. This has been given through the interest in the electrical work at Delaware College of certain manufacturing companies, principally the Baldwin Locomotive Works, of Philadelphia; the Joseph Bancroft & Sons Company, Rockford, Wilmington, and the E. I. Dupont de Nemours & Company, Wilmington. This apparatus includes one 5 horse-power continuous-current shunt-wound motor from the first of the above companies and two small motors and a voltmeter from the Bancroft works. The larger part, however, comes through the courtesy of Mr. Alfred Du Pont, namely, one 2 horse-power direct-curent motor, two transformers, complete patterns for an alternator of 40-kw capacity, four La Roche meters and one Queen & Company ammeter. The department has also recently received from the Navy Yard, New York, a standardized 32-cp lamp for accurate testing with the photometer, and a hydraulic ram from the Gould's Manufacturing Company, Seneca Falls, N. Y. The apparatus for the dynamo laboratory, while not for the most part of the latest designs, will however enable work under Prof. A. J. Wood to be carried on much more successfully than it could without this additional equipment.

Trade Notes.

THE POLICE TELEPHONE & SIGNAL COMPANY, of Chicago, has changed its name to Chicago Fire Alarm Company.

THE WILLARD STORAGE BATTERY COMPANY, Cleveland, O., will supply the storage batteries for the electric launches at the St. Louis World's Fair.

OIL FILTERS FOR FRANCE.—A cable order from Paris, France, for a large shipment of Cross oil filters has been received by the Burt Manufacturing Company.

THE HERTNER ELECTRIC COMPANY, Cleveland, O., has closed a contract for some special motors for the operation of electric launches at the St. Louis Fair.

THE STERLING ELECTRIC COMPANY, Lafayette, Ind., has just completed the installation of common battery equipments at Gainesville, Tex.; Denton, Tex.; Springfield, Ohio, and Elyria, Ohio. It reports a good demand for this class of work for the coming year.

STORAGE BATTERIES FOR RAILWAY PLANTS.—The Electric Storage Battery Company, Philadelphia, devotes its Bulletin No. 81 to a description of the installation of Chloride accumulators for the San Francisco, Oakland & San Jose Railway Company. The plant is well illustrated.

THE H. O. S. ENGINEERING COMPANY, 88 Warren Street, New York, is sending out to the trade its bulletin No. 41, relating to covers for "H. O. S." panelboard cabinets. Three styles of these covers are illustrated and general data as to cabinets and covers are given. Tabulated price lists and code words are also included.

THE STANDARD ELECTRICAL MANUFACTURING COMPANY, of Niles, O., has opened a New York office at 19 Park Row with Mr. J. Rice, general sales manager in charge. Stock will be carried for quick delivery and partict.. r attention given to pushing the Standard Company's latest additions to its lines—the 3¾-inch frosted bulb reflector lamp.

RAILROAD BONDED INDEBTEDNESS.—Poor's Railroad Manual Company, New York, has issued a supplement to its Manual of Railroads, giving a great deal of information about railway bonded indebtedness. It contains all important facts required by investors, bankers and others relative to the financial status of the leading railway systems in the United States.

"GOOD MOTIVES" is the title of a little double-fold pamphlet of recent issue by the Peerless Electric Company, Warren, O. The subject is Peerless motors, and the illustrations show motors of different sizes, and motors coupled, either by belt or gearing, to machine tools of various kinds. The text matter is an interesting argument in favor of the "Peerless" machines. The company's fan motors, transformers and lamps are also well known to the trade.

PHOSPHOR-BRONZE.—Price list No. 22 of "Elephant Brand" phosphor-bronze has been issued by the Phosphor-Bronze Smelting Company, Ltd., 2200 Washington Avenue, Philadelphia, Pa. It is replete with information regarding phosphor-bronze in rolls and sheets, wire, rods, wire rope, ingots, castings, etc. The company's new rolling mill is now in successful operation. The company carries on hand a well-assorted stock of manufactured goods for prompt supply.

THE EAGER ELECTRIC COMPANY, Watertown, N. Y., has issued a neat catalogue on the subject of its direct-current generators and motors for lighting and power. The generators are of the direct-connected or belted types. The company also makes motor generators, plating dynamos and boosters. These machines are of excellent design and are illustrated. The catalogue gives complete information and data regarding the various types of machines produced by the company.

McLEOD, WARD & COMPANY, 27 Thames Street, New York, in a little pamphlet admonish the readers thereof to save their eyes. While the admonition is quite justifiable these strenuous days, the pamphlet points to a way to put the suggestion into practice, namely, by using the Kinsman type of lamp as manufactured by this firm. The desk lamps of this firm are extensively used and well known. This pamphlet gives complete information regarding these lamps in their different styles.

"BEFORE AND AFTER."—An attractive pamphlet has been issued by the Calculagraph Company entitled "Before and After." This title refers to the use of the Calculagraph for timing telephone toll messages. It tells a little story as to what was done by the old method of figuring and comparing time tickets and the great saving that was effected when the Calculagraph took all of this mechanical work from the operator. The pamphlet is a convincing argument for the use of the Calculagraph.

MINE AND ORE CARS.—The Atlas Car & Manufacturing Company, Cleveland, Ohio, has issued a very completely illustrated catalogue of its products, which consist of dump cars of every description for smelting and roasting plants, furnaces, foundries, cement works and general use, also overhead trolleys, industrial railway equipment, frogs, switches, rails, etc. The illustrations show this varied line of articles, each one being accompanied by a description, data, etc. The catalogue (No. 1018) has over 100 pages and covers the ground very thoroughly.

POWER TRANSMISSION APPLIANCES.—Price list No. 10 of power transmission appliances of the Case Manufacturing Company, Columbus, Ohio, takes up no less than 136 pages. There is a vast number of articles listed, and the final production of this list represents a great amount of time, labor and care. The pages are of a bright yellow paper, which is very pleasing to the eyes. Among the articles included may be mentioned: hangers, bearings, belting, bolts, conveyors, couplings, gears of all kinds, elevators, power shovels, jacks, pulleys, transmission rope, scales, truck, etc., etc.

GAS ENGINES.—The Walrath gas and gasoline engines as manufactured by the Marinette Iron Works Manufacturing Company, Marinette, Wis., have become pretty well known since their introduction to the market. The engine possesses many features that appeal to power users the more they become known. A catalogue issued by the company gives detailed information regarding this well-known type of engine, and several illustrations show the different designs. Engines direct-connected to electric generators are also shown. One of the engines shown, of the 3-cylinder type, is of 150 horse-power.

WIRES AND CABLES.—The Hazard Manufacturing Company, Wilkesbarre, Pa., gives very complete information—much of it in tabular form—of its extensive line of products, in a neatly gotten up pamphlet of recent issue. This company, as is well known, manufactures electric wires and other equipment for electric railways, electric light and power circuits, telephone and telegraph systems. All copper wires used in the manufacture of its insulated wires and cables are drawn in the company's own wire mill. The pamphlet is copiously illustrated, showing sections of cables of many varieties and for all purposes. The pamphlet is replete with tables.

THE WILLARD STORAGE BATTERY COMPANY, of Cleveland, is now fully settled in its new plant at the corner of St. Clair and Water streets. There are two buildings, embracing over 25,000 sq. ft. of floor space. The company has recently installed a large amount of new special machinery, and is now prepared to handle more than double its former output. It is manufacturing batteries for all purposes and just now is doing an unusually large amount of work for railway signal outfits, electric launches and electric automobiles. Improved processes of manufacture and close attention to mechanical details have resulted in a considerable decrease in the weight of the Willard battery and at the same time the efficiency has been increased.

KELLER, PIKE & CO., of Philadelphia, have been awarded the contract for the complete mechanical and electrical equipment of the new Court House for Camden County, N. J. This building, which has been designed by Messrs. Rankin, Kellogg & Crane, will cost about $700,000. The equipment consists of return tubular boilers of 300 hp, two simple high-speed engines, two direct-connected 55-kw. generators, foundations, switchboard, power steam piping, heating and ventilating systems, with Johnson temperature regulation, electric motors for fans, blowers and pumps, electric elevators, and electric light and power wiring. It will be recalled that the same company recently secured the large contract for the new Pennsylvania state capitol.

H. W. JOHNS CONVENTION.—The H. W. Johns-Manville Company held a convention last month at New York and Hartford, Conn., of its branch managers, department managers and salesmen. The company has issued a pamphlet giving a report of the meeting. The programme was a varied and extensive one, the subjects of the papers referring to matters directly or indirectly related to the company's field of work. Representatives to the number of about 35, from all parts of the country, were present. The object of the convention was to bring all branches into closer touch with one another and to afford opportunity for a general discussion of all the greatly varied lines manufactured by the company. The meetings were held at Hartford on February 15, 16 and 17, and at New York on February 18, 19 and 20.

HYDRO-CARBON PAINTS.—The Hydro-Carbon Manufacturing Company, Denver, Col., has just issued a couple of small pamphlets relating to its hydro-carbon paints, their advantages and uses. It is stated that this paint possesses to a high degree the property of withstanding extreme climatic conditions and yet retains its preservative value. The basis of the paint is a hydro-carbon ore, which is stated to be a natural product of petroleum mined in Utah and Colorado. It is claimed that the paint resists the corrosive action of steam, vapor, water and gases. One of the pamphlets is given up entirely to a dissertation on iron corrosion and its prevention. The information given on the general subject is valuable to those concerned. The Hydro-Carbon Manufacturing Company will be glad to send copies of these pamphlets on application.

STURTEVANT CATALOGUE.—The second edition of catalogue No. 115, the general condensed catalogue of the B. F. Sturtevant Company, Boston, Mass., is now ready for distribution. This catalogue describes and illustrates a number of new apparatus manufactured by this enterprising company, among which are a new type of hand-blower, several new types and sizes of forges, new sizes of vertical single and double engines, a new type of enclosed vertical compound engines, new type of semi-enclosed bi-polar and 4-pole motors, new sizes of generating sets with vertical compound engines, factory equipments, such as bench-legs, pattern storage shelf brackets, electric hoists, cast iron sinks, trench cover-plates, etc.; industrial railway equipments, such as cars, truck ladles, turntables, T-rails, etc. It also contains a description of the various Sturtevant systems, such as heating and ventilating, special ventilating, drying, conveying and mechanical draft systems.

THE NATIONAL ELECTRIC COMPANY, successor to the Christensen Engineering Company, Milwaukee, will exhibit its electrical and air brake apparatus at the St. Louis Fair. Part of its electrical exhibit will include a 1500-kw alternating-current generator. This unit will be in operation at the central power station, furnishing power for various purposes. In addition, a number of smaller alternating and direct-current machines will be exhibited at its space, including a very complete exhibit of the Christensen air brake equipment, so well known in the street railway field.

THE WELLMAN-SEAVER-MORGAN COMPANY and the Electric Controller and Supply Company, of Cleveland, are now occupying a handsome and spacious office building erected exclusively for their use adjoining the plant on the Pennsylvania tracks and Central Avenue, Cleveland. The Electric Controller & Supply Company occupies practically one entire floor, including general office room, six private offices and large drafting room. All rooms in the building are illuminated with Nernst lamps and over each table in the drafting rooms are single glower Nernst lamps suspended from cords. The drafting rooms are connected by dumb waiter with the blue-print room in the basement, which is provided with electric blue-print machines. In the basement there are dining rooms for officials and office employes. On each floor there are two toilet rooms, and there is a private bath room and barber shop for officials. There is a private telephone exchange connecting all offices and departments in the building, as well as throughout the plant, and there is a Postal telegraph office in the main entrance. The various offices are equipped with every convenience and are tastefully and handsomely furnished.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED MARCH 15, 1904.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., New York.]

754,406. ELECTRICALLY OPERATED STOPPING MEANS AT RAILWAY DANGER SIGNALS; William L. Adamson, Philadelphia, Pa. App. filed June 12, 1903. When the signal at the roadside is thrown to danger from a tower, a contact is at the same time thrown into position to be struck by a train to close a circuit which shuts off the steam on the locomotive and prevents the train from running past the signal.

754,414. OUTLET FOR INTERIOR CONDUITS; William F. Bossert, Utica, N. Y. App. filed Dec. 19, 1903. A sheet metal sleeve is adjustable in position in the front opening of the box to be made flush with the plaster.

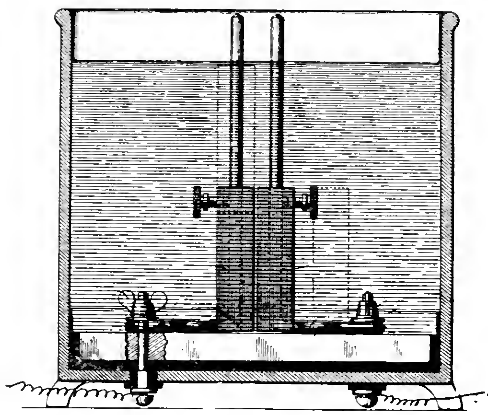
754,429. MEANS FOR ELECTRICAL DISTRIBUTION; John L. Creveling, New York, N. Y. App. filed May 10, 1901. A centrifugally operated circuit controller and rheostat for train lighting systems.

754,451. ELECTRICAL WATER HEATER; Harry M. Hill, St. Louis, Mo. App. filed June 1, 1903. Two carbon electrodes adjustably mounted in a tank; the water circulating between them becomes heated by the passage of current.

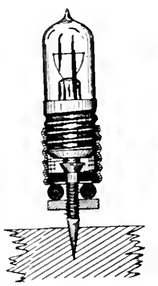
754,465. AUTOMATIC ELECTRIC HEAT REGULATOR; Daniel N. Leib, Elkhart, Ind. App. filed April 10, 1902. Details.

754,473. GUIDE WHEEL; Alexander H. Mathesius, Brooklyn, N. Y. App. filed Feb. 14, 1901. The shape of the tread of a trolley wheel and the cross section of the conductor are so related as to reduce slipping and abrasion of the contact surfaces.

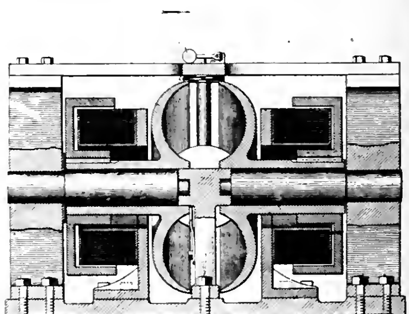
754,496. LIMITING DEVICE FOR ELECTRIC CIRCUITS; Charles W. Potter, Denver, Col. App. filed Feb. 10, 1902. A device applied in the meter loop which is adjusted so that upon an increase of the load above the amount contracted for, the device will automatically cut off the current.



754,451.—Electrical Water Heater.



754,762.—Electric Socket Support.



754,804.—Speed Regulating Magnetic Clutch.

754,505. AUTOMATIC CIRCUIT BREAKER; William M. Scott, Philadelphia, Pa. App. filed June 18, 1903. Various improvements in the details of construction.

754,534. THERMOSTATIC GAS DETECTING MEANS; James E. Baldwin, East Williston, N. Y. App. filed Sept. 10, 1902. Details.

754,555. AUTOMATIC FIRE ALARM; Mason K. Fred, Pleasanton, Tex. App. filed March 9, 1903. A protective fusible wire is connected in parallel with an alarm and a resistance and in series with a battery; the resistance normally prevents the alarms from ringing, but the destruction of the fuse wire sends the entire current through the alarm.

754,565. ELECTRIC RAILWAY; Rudolf Alfred Emil Haber and Hans Hugo Carl Behn-Eschenburg, Zurich, Switzerland. App. filed Dec. 23, 1901. An application of the Ward Leonard railway system relating to the use of alternating current line sections of different voltages; for example, a high voltage for the open country and a low voltage for large railway stations.

754,596. GAS DETECTOR; George A. Nelson, Providence, R. I. App. filed Feb. 10, 1903. A balloon which floats in a normal atmosphere will lower in the presence of a gas and close an alarm circuit.

754,622. ELECTRIC CLOCK; David W. Thompson, Chicago, Ill. App. filed Dec. 5, 1895. Details.

754,631. LAMP FOR CANES, UMBRELLA STICKS OR THE LIKE; James W. Allen, St. Louis, Mo. App. filed Nov. 2, 1903. A bull's-eye electric lamp and battery all located in the head of the cane.

754,656. ELECTRIC FURNACE; Charles Albert Keller, Paris, France. App. filed Jan. 17, 1902. (See page 608.)

754,660. RHEOSTAT; Lamar Lyndon, New York, N. Y. App. filed Aug. 8, 1902. A rheostat which by being properly connected with a translating device and the line, will permit the total current to flow through the device when it is desired, and with which it will be possible to vary at will the potential of the current in the device from zero to maximum.

754,666. INDUCTION COIL; Reuben Miller, Jr., Pittsburg, Pa. App. filed Jan. 7, 1904. A magnet operating an interrupter is in circuit with all of the primaries of a number of induction coils, supplying the spark respectively to the cylinders of a multiple-cylinder engine.

754,681. ELECTROMAGNETIC DEVICE; Eugen K. Muller, Zurich, Switzerland. App. filed Sept. 20, 1902. Details of an alternating-current magnet adapted for massage purposes.

754,689. ELECTRIC SELECTIVE APPARATUS; Frank D. Pearne and Charles L. Krum, Chicago, Ill. App. filed Feb. 3, 1902. A sensitive relay by which one or two or three branch circuits may be closed in combination with a magnetic lock arranged to hold the selected branch in a closed condition.

754,692. RHEOSTAT; Claude R. Pitrat, Amsterdam, N. Y. App. filed Aug. 8, 1903. Details.

754,694. ELECTRIC POCKET LAMP; Angelica E. Post, Boston, Mass. App. filed Dec. 30, 1903. A flat battery case for the vest pocket, the cover having a lamp which can be thrown into circuit at will.

754,756. PROCESS OF SEPARATING ORES FROM MAGNETIC GANGUE; Thomas A. Edison, Llewellyn Park, N. J. App. filed May 29, 1903. App. filed March 15, 1903. The small proportion of non-magnetic material in a body of ore is recovered by first grinding to a fineness to free the non-magnetic particles, then adding a larger bulk of the coarser non-magnetic material, then passing the mixture through a magnetic separator to separate the entire body of non-magnetic material and finally separating the coarser material from the original non-magnetic material.

754,762. ELECTRIC SOCKET SUPPORT; Edwin R. Gill, New York, N. Y. App. filed March 14, 1902. A lamp socket having brads in its base to puncture the insulation of conductors and a central screw by which the socket can be supported on any structure.

754,778. TROLLEY WHEEL RETAINER; James A. Kelpatrick, Niles, Ohio. App. filed Dec. 19, 1903. Details.

754,804. SPEED REGULATING MAGNETIC CLUTCH; Charles A. Pratt, Oakpark, Ill. App. filed Dec. 7, 1903. Two transmission disks mounted to rotate independently and having opposed spherical faces in which friction pulleys are located. By shifting the position of the pulleys, the difference in speed of rotation is obtained.

754,832. ELECTRIC RAILWAY PLOW; John H. Akers, Washington, D. C. App. filed Aug. 8, 1903. Details.

754,858. STORAGE-BATTERY TRAY; Thomas A. Edison, Llewellyn Park, N. J. App. filed Nov. 28, 1902. (See page 608.)

754,859. REVERSIBLE GALVANIC BATTERY; Thomas A. Edison, Llewellyn Park, N. J. App. filed Nov. 28, 1902. (See page 608.)

754,863. ELECTRICAL PLUG AND RECEPTACLE; Gilbert W. Goodridge, Bridgeport, Conn. App. filed Oct. 9, 1903. Details.

754,868. FIRE AND WATER-PROOF INSULATING COVERING FOR METALLIC SURFACES; John A. Heany, Philadelphia, Pa. App. filed May 10, 1902. An agglomeration of a gluey substance and asbestos.

754,884. CABLE CLIP; James McFarlane, Allegheny, Pa. App. filed June 3, 1903. A strap having a hook at each end which passes over the wire in opposite directions.

754,885. AUTOMATIC FIRING DEVICE FOR ORDNANCE; Ludwig Obry, Triest, Austria-Hungary. App. filed Sept. 12, 1903. Details.

754,894. SELF-ADJUSTING WHEEL; Edgar A. Root and Charles M. Wallace, Huntington, W. Va. App. filed May 23, 1903. Details.

754,904. WIRELESS SIGNALING SYSTEM; Harry Shoemaker, Philadelphia, Pa. App. filed June 11, 1902. A freely oscillating circuit, an inductance winding included therewith and a radiating surface connected to the terminals of the winding.

754,935. RINGING AND LISTENING KEY; Charles H. North, Cleveland, O. App. filed Sept. 14, 1901. Details.

Electrical World and Engineer

THE CONSOLIDATION OF "THE ELECTRICAL WORLD" AND "ELECTRICAL ENGINEER."

VOL. XLIII. NEW YORK, SATURDAY, APRIL 2, 1904. No. 14.

ELECTRICAL WORLD AND ENGINEER.

Published weekly by the

McGRAW PUBLISHING CO.

114 LIBERTY STREET, NEW YORK.

TELEPHONE CALL: 7605 CORTLANDT. CABLE ADDRESS: ELECTRICAL, NEW YORK.

EDITED BY T. C. MARTIN AND W. D. WEAVER.

CHICAGO OFFICE - - - - - - 1139 Monadnock Block.
PHILADELPHIA OFFICE - - - - - - 929 Chestnut Street.
EUROPEAN OFFICE, Hastings House, Norfolk St., Strand, London, Eng.

TERMS OF SUBSCRIPTION.

United States, Canada or Mexico	Per year, $3.00
Foreign Countries, within the Postal Union	6.00
Great Britain and Ireland	25 shillings
Germany	25 marks
France	31 francs
Single copies	.10

Remittances for foreign subscriptions may be made through our European office.
In requesting your address changed give OLD as well as new address.

Entered as second-class mail matter at the New York Post Office.

NEW YORK, SATURDAY, APRIL 2, 1904.

CONTENTS.

KIND WORDS.

The recent issuance of our Thirtieth Anniversary Number has been the subject of a great many kind letters and messages from readers and advertisers in this country, while we are now beginning to receive such congratulations in equal volume from abroad. Up to the present time, considerably over 500 such communications have reached us, and we feel that we can do no less than extend here our sincere thanks for these heartily appreciated expressions of esteem and good will.

UNDIGESTED EXPORTS.

While the country may have been suffering from the amount of "undigested securities" on hand, it would appear that the effect of financial dullness on foreign trade has not been serious, but that our exports of raw material, or "undigested exports," have continued heavy, and that the quantity of manufactures sent abroad, or "digested exports," has shown a notable gain during the past year. What is needed in this foreign trade is to lessen the "undigested" part of it by converting it into "digested," just as Europe does in her trade with us. She does not send us stuff in crude form and big bulk, but ships her goods in neat little packages; so that while the steamers may appear to come in light, a few pounds represent in value several tons of the raw material, in food, cotton, etc., that we may be sending across the Atlantic.

Meantime it is worthy of note that for the eight months including February the total exports from the United States were valued at one billion forty-eight million dollars against nine hundred and eighty-two millions, in 1903, while the imports fell off, representing six hundred and fifty-four millions against six hundred and eighty-one millions. A large proportion of this export is manufactures, being fully two hundred and eighty-eight millions as against two hundred and sixty millions in the previous period. The month of February alone showed thirty-eight millions against thirty-four millions in 1903. All this is very satisfactory in view of the depressed or agitated condition of more than one part of the globe. The electrical portion of this trade is holding its own very well.

SIMULTANEOUS TELEGRAPHY AND TELEPHONY.

In 1882, Van Rysselberghe—an ill-rewarded Belgian—first proposed the conjoint use of telephone circuits for both telegraphy and telephony simultaneously, and initiated ingeniously the use of composite circuits for such purposes. At the present time, a large number of long-distance telephone circuits are used for telegraphic purposes over and above their regular telephonic duty. The general and striking facts concerning composite circuits are fully set forth in the very interesting article by Mr. L. W. Stanton, on page 635. Broadly speaking, such a circuit passes both low-frequency telegraph impulses and higher-frequency telephone currents, receiving these in respectively selective branch circuits. It is curious to note that the signaling, or calling, telephone currents ordinarily belong to the low-frequency class, and that consequently special precautions are sometimes necessary to keep these telephone currents from interfering with the telegraph. Yet another kind of composite circuit not coming within the scope of the article, is the conjoint use of telephone receivers with telegraph apparatus under the name of the phonoplex system, which is in fairly extensive use. In this arrangement high-frequency impulses are used to actuate the telephone receivers for telegraphic instead of telephonic purposes.

These technical aspects and considerations have their value and importance, but they seem to us minimized, comparatively, by the commercial possibilities, outlined briefly by Mr. Stanton at the conclusion of his very suggestive article. The details given by him as to the amount of work already done in the application of the system will astonish most people, including not a few familiar with the twin telegraphic and telephonic arts. It is true that the figures quoted deal with what is going on in one section of the independent telephone field, but there could be a good deal said from the Bell side also, although the management have so far preferred to maintain an exuberant reticence as to what they are doing in that respect.

And this brings out the "political" aspects, as noted by Mr. Stanton as follows: "We cannot but expect to see two great telephone companies competing for both telegraph and telephone business, which will eventually bring about a consolidation between one of the telephone companies and one of the telegraph companies. This may compel an alliance between the two remaining companies, for the telephone and telegraph companies combined can reduce operating expenses very materially. The same official staff, the same buildings, the same conduit system, pole lines, etc., can be used by the two; and many other decided economies could be effected." There is food for thought here, especially as the idea is predicated upon such facts as those which Mr. Stanton sets forth.

Bell Telephone Figures

Very impressive are the statistics furnished by Mr. Fish as to the workings of the Bell telephone system last year, in his annual presidential report to the stockholders printed elsewhere. The financial condition is reflected in the ledger balances of $13,319,533 cash and deposits, and $22,397,407 bills receivable; offset by but $8,931,804 bills payable, nearly $3,000,000 of which was the dividend payable in January. The company earned $16,545,632, paid $8,619,150 in dividends and carried to reserve and surplus, $1,945,514. That looks like a pretty stable and comfortable business, whatever the "independents" may be doing—and they are doing a good deal. Indeed it is remarkable that the growth is so well kept up, and it is evident that whatever losses from competition are sustained in rural territories, the growth in the cities has fully offset them. The growth is also shown by the fact that new construction and real estate last year required a sum of $35,368,700. The increase in stations was 247,184 up to a total of 1,525,167, and the mileage of circuit increased 677,229 miles up to the splendid total of 3,958,891.

The Reciprocating vs. Turbine Types of Steam Engines.

During the past year or more the steam turbine has almost entirely monopolized attention in the field of steam engineering, and its advocates have not been sparing in setting forth invidious comparisons with the reciprocating type of engine which, indeed, by some of these has been treated as already an anachronism. Perhaps this aggressive spirit has been fostered by the silence of those with whom lay the defense of the type attacked, but on another page we print an article in which at last the challenge is accepted and the issue most vigorously met. The case which Mr. Seymour makes out is a strong one, fortified as it is by data drawn, not from shop tests, but from the results of trials conducted by disinterested engineers. The remarkable efficiency of the engines tested, and particularly the efficiency at light load, shows that the reciprocating engine has had a margin of undeveloped economy which even in the recent past has been overlooked. The showing, in fact, is such that the steam turbine is put on the defensive as regards economy, and the issue presented can only be met by reports of tests under trial conditions and disinterested supervision similar to what obtained in the cases cited. Finally, all, we believe, will concur with Mr. Seymour that in general comparisons of performance of the reciprocating and turbine types of engines, the new-comer should select the latest development of the older type and not evolve for its purposes an "average" type—in other words, should squarely meet its real competitor.

Legal Aspects of Electric Affairs.

Mr. Ball's paper on this topic, printed elsewhere, gives an instructive view of some English precedents in decisions involving particularly the rights of operating companies. Although English and American decisions rest in general upon the same organic body of common law, yet the statutory provisions in the two countries are not always parallel and the general tendency of decisions is not precisely in the same direction. Mr. Ball deals with the liabilities of supply companies under the heads of negligence and nuisance. Now, from the general trend of recent opinions it is quite safe to assert that these two divisions as made here and in England would differ greatly in relative importance. The point of view here and there differs more than the statutes differ, and it is often the point of view that determines the final result. Broadly, the law regarding nuisances is far more rigorously applied in England than it is here. An operating company for electric supply, or in fact an industrial establishment of any kind, can seldom be successfully attacked here under the general principle of nuisances. Enjoining an electric light company on account of excessive vibration produced by its machinery, as was done in England the other day, would be difficult if not impossible in any American city. It has proved to be next to impossible here to really abate a smoke nuisance effectively. In general, the rights of the private citizen or private householder as against the acts of his neighbors are upheld very ineffectively, under American decisions. The idea of individual liberty is carried so far here that in practice a man may infringe the natural rights of his neighbors to a very objectionable extent without serious hindrance. Electric supply companies as a whole get the benefit of this sentiment in comparative immunity from a very annoying class of suits.

In another important particular the American plant has an advantage. In England there is a group of Acts dealing with the liability of employers and the rights of workmen in a fashion far more severe than any American statutes. On their faces English and American laws on these subjects are to about the same purport, but the former are backed up by a far more drastic series of decisions than the latter. We referred not long ago to a decision holding an employer responsible because a workman on the roof of a small building under construction was struck by lightning. Very likely the decision may be reversed on appeal, but it would have been practically impossible to get such a decision here, even in a jury trial much less from the Court. Juries are as a rule very liberal to employees who are injured, but they draw the line somewhere. On the other hand, so far as liability in case of injury to persons not employees is concerned, the American jury goes to considerable lengths. It will hold a company up in a matter of alleged negligence on very small provocation. Were it not for this tendency, fraudulent suits against street railway companies in particular would be far less frequent than experience has shown that they actually are. Sometimes claims of the most absurdly unjust character are successfully pushed, and the result is that operating companies have time and time again settled unjust claims out of court, knowing from bitter experience the treatment that they are likely to get at the hands of a jury. The "ambulance lawyer," so called, is a product of the easy jury, and much just complaint has been made of the practice of bringing suits ostensibly in the interest of the injured plaintiff, but really in the interest of the attorney. In such instances it seems to us that the fault lies largely with the forms of procedure that have gradually grown up.

We do not believe that the ordinary jury is hopelessly incompetent and prejudiced. On the other hand, it could by proper selection unquestionably be made very much better than it is. The ordinary jury is scarcely up to the level of the panel from which it is drawn, owing to the kind of selection which the respective attorneys have fallen into the vicious habit of making. Too many challenges and far too trivial causes are often allowed, and it seems to us that the firm exercise of a wise discretion by the Court could be and should be made to remedy the evil. The rules of evidence now in use are hardly suited to put the facts clearly before the jury that is obtained, and when there is, as not infrequently happens, an obvious effort on the part of the attorneys to keep pertinent facts from the ears of the jury, one can hardly expect to escape from questionable verdicts. But perhaps the most serious obstacle in the path of strict justice is the secrecy that often involves the real parties to the suit. As procedure now is, it is likely enough that while the ostensible parties are a grievously injured citizen and a wealthy and negligent corporation, the real parties may be an "ambulance lawyer" and a casualty insurance company. If the jury knew this they would be far less likely to be misled by unreasoning sympathy than is now the case. It is perfectly true that the jury trial has come to be looked at askance and held in some contempt, but the fault is not so much the fault of the system as of the way, cumbersome and indirect, in which it is worked. We are not aware that it works any better in England than here, perhaps not quite so well to judge from the large number of mistrials, but the fault is not inherent in the system. By and large, American electrical companies and interests are pretty well looked after by the laws, but the system is far from perfect, and we may as well keep our eyes frankly open to its defects with a hope of an ultimate remedy.

Shielded Balances.

On page 647 we print this week an interesting article by Mr. G. A. Campbell, which has many practical applications. When we measure the resistance of any conductor, say a coil of insulated copper wire, by the ordinary continuous-current Wheatstone bridge, we obtain a perfectly definite result, at any one temperature, if all the conductive connections are good, and if there are no appreciable leakages, or defects in insulation. If, however, we use an alternating-current Wheatstone bridge, the balance involves the magnitudes of both resistance and reactance. Unless both these quantities are balanced a perfect balance in the bridge is impossible. Moreover, if the telephone be employed as the measuring instrument in place of the galvanometer, it is most difficult to secure a complete zero of sound. This difficulty increases with the frequency, and at a frequency of 1,000 cycles per second, which is not high from a telephonic standpoint, Mr. Campbell shows that the dielectric susceptance of the air all round the apparatus plays a very appreciable part. In fact, air, while a perfect insulator for direct currents, is no insulator in this sense, for alternating currents. The alternating-current circuit is subject to all-pervading electrostatic susceptance, resembling leakage through the air; just as the magnetic circuit is subject to all-pervading magnetic leakage through the air. Air ceases, in fact, to be an insulator for the alternating-current circuit, just as in the magnetic circuit. The air acts in the same manner in both the alternating current and the magnetic circuits, that at all telephonic frequencies the energy is stored in the air elastically—electrostatically in the one case, and magnetically in the other—without any necessary waste in the process.

It is not merely the disturbance of the position of balance by the presence of the susceptance currents in the air, but also, as pointed out in the article, the liability to variation in the balance by such extraneous changes in the air currents as by the movements of the body of the operator. In such upper-frequency alternating-current bridge measurements, the operator may be said to have a personal equation that is not only mental, but also physical. The solution of the difficulty proposed by Mr. Campbell consists in making all the air susceptance currents definite and invariable, by enclosing the essential parts of the apparatus in metal boxes, or condenser shields. The various elements of the bridge are provided, as explained, with connected shields, and the entire apparatus is placed in a floating shield. This arrangement has the effect of adding certain definite susceptances to each of the conductances in the bridge; but these susceptances are at least invariable, and are capable of elimination in deducing the results of observations.

The plan somewhat resembles the expedient adopted in electrometers of the attracted-disc type. The force attracting two opposed parallel plane surfaces or discs at a definite distance apart in air, for any given difference of potential between them, is known to be $e^2/8\pi$ dynes per square centimeter, where e is the electric intensity in abstatvolts per centimeter. Near the edges of the discs, however, the electric intensity is weakened, and bent out of the perpendicular, in a complicated manner. In order to restore definiteness and simplicity to the arrangement, a guard ring is arranged so as virtually to extend the plane surface of the disc, and keep the electrostatic flux density sensibly uniform all over the surface of the disc, where the attractive force is measured. In a certain sense the expedient given in the article for restoring definiteness and simplicity to the alternating Wheatstone bridge, consists in supplying virtual guard rings to all the apparatus capable of being affected by the alternating electrostatic flux. In wireless telegraphy and in researches on Hertzian waves, the detecting apparatus has frequently to be included in metallic boxes to keep electrostatic waves *out*. In the case here considered Mr. Campbell places his apparatus in metal boxes to keep electrostatic waves *in*.

We shall hope to receive a subsequent article from Mr. Campbell giving the results of the practical use of the apparatus. We regard this article as of importance, not merely from its technical value, but also as marking what is in our judgment a decided advance in the policy of the long-established telephone industry. We have long been aware that telephone engineers have carried on valuable and important technical researches in connection with their work, which researches the telephone administration always decided to withhold from publication, as a matter of policy. This policy we have always protested against as short-sighted, imprudent and immoral. None will deny that an industry has a perfect right to withhold trade secrets and manufacturing data that may have cost time and industry to acquire. We offer no criticism against the policy of withholding trade secrets, and none would be likely to be influenced by such criticisms if offered. But when the matters relate merely to technology, or applied science, as distinguished from business or manufacturing details, we think everyone will agree that there is no use in withholding from publication matters which the general progress of science will inevitably make known within a few years at most, and which if made known only redound to the credit of the industry disclosing, while adding to the world's general stock of knowledge in applied science. When the knowledge is arrived at by outsiders, in the regular subsequent course, the original work done earlier by the industry has lost credit, and has lost the evidence of progress. The time has gone by, let us hope, forever, when a chemical formula, like that of Greek fire, could be kept a secret in the arsenal of Constantinople for nearly six hundred years. For the above reasons we welcome Mr. Campbell's article as a contribution of telephone engineering to technology, which is a good augury for future policy.

Tesla Split-Phase Motor Patent Decision.

Judge Kohlsaat on Saturday of last week handed down a decision in a case involving the Tesla split-phase motor patent brought before the U. S. Circuit Court for the Northern District of Illinois, which decision upholds the Tesla patent and grants an injunction against the use of the split-phase principle in a wattmeter made by the defendants in the action. The opinion cites the opinions of Judges Archbold, Hazel, Townsend and Lacombe sustaining the patent, and the opinion of the Court of Appeals reversing the Lacombe decision, which latter ruling was followed by Judge Colt in another case. All of the above cases have been reported in these columns.

Judge Kohlsaat says that the decision of Judge Lacombe was reversed largely upon the ground that it did not appear from the record that Tesla's invention was not anticipated or described in a paper read by the late Prof. Ferraris before the Royal Acadmy of Sciences, of Turin, Italy, on March 18, 1888, and published, in part, in an electrical journal issued at Milan on April 22, 1888. He holds, however, that in the later cases—those decided by Judges Archbold and Hazel—the records, together with certain original proofs offered in the present case, establish that Tesla's invention in suit antedated the Ferraris article, was original with Tesla, and that his patents are valid.

Discussion of Institute Papers.

The regular monthly meeting of the American Institute of Electrical Engineers last Friday was devoted to the discussions of papers of Messrs. Blackwell, Stillwell, Hewlett and Moody, full abstracts of which were printed in our issue of March 19. The following council nominee ticket for the coming election was announced: President, Mr. John W. Lieb, Jr.; vice-presidents, Messrs. W. E. Goldsborough, J. J. Carty and Samuel Reber; managers, Messrs. L. A. Ferguson, H. G. Stott, J. G. White and S. S. Wheeler; secretary, Mr. R. W. Pope; treasurer, Mr. G. A. Hamilton.

The discussion of the papers of the evening was very extensive, as may be judged from the fact that a transcript in full would cover about 12 of these pages. Consequently, it is only practicable to give here a mere summary, the reader being referred to the report in full, which in due course will be published by the Institute.

Those taking part in the discussion were Messrs. Chesney, Perrine, Dow, Peck, Townley, Mershon, Skinner, Arnold, Stott, Scott, Nunn, Lincoln, de Muralt, Lyford and Stillwell. Written contributions to the discussion were submitted by Messrs. Tobey, Hazard, Roberts, Bayne, Walters, I. A. Taylor, D. C. Jackson, Wright, J. B. Taylor and N. M. Snyder.

The greater part of the discussion of the evening was on the relative safety with respect to fire risk, of oil and air-cooled transformers, and provisions that should be made to reduce the fire hazard in the case of the former. The opinion was almost unanimous that the oil transformer, if proper precautions are taken, is safer than the air transformer. In support of this view, Dr. Perrine mentioned that the fire underwriters, and particularly the instructions of the Mutual Fire Insurance Company, favor the oil over the air-cooled transformer. Mr. Peck stated the case against the air-blast transformer, which he said is more susceptible to damage by fire from static discharges, arcs, bad contacts, etc., than the oil-insulated transformer; though, he added, on the other hand, owing to the small amount of combustible material in the former, it is possible to have such material entirely destroyed with comparatively little fire risk to neighboring apparatus or buildings. As to precautions to be observed in installating oil transformers, all concurred that the case should, where possible, be made of riveted boiler iron which will withstand a pressure of 100 pounds per square inch, and that it should be properly vented. Mr. Peck said that where sheet iron construction is necessary the case should be made practically air-tight and provided with a very large safety valve, so that an internal explosion cannot burst the case. It was generally agreed that transformer units should be located in fire-proof compartments and some advocated locating them in vaults. In any case the transformer case should be so constructed as not to be broken in the case of the floor or walls of a burning building or heavy weights falling upon it.

Mr. Mershon disapproved of a bottom drain, owing to the fact that as oil went out air would enter the transformer case, and might cause an explosion. He described an arrangement which he had used which provides for pumping water into the bottom of a transformer, which forced the oil out at the top. He dwelt upon the necessity of so arranging the draining system that in case of falling floors or walls the pipes would not be broken. One suggestion was that the transformers should be placed in vaults that could be closed and to which steam could be admitted to smother flames in case of the oil taking fire. Several of those taking part in the discussion drew attention to the fact that the oil-cooled transformer was not an extreme fire hazard, if proper precautions were observed, and that this should be made plain in order that the discussion would not cause alarm.

The matter of transformer terminals was considered in the discussion. Mr. Skinner pointed out the difficulty of bringing out such terminals from transformers of 20,000 volts or more. This trouble was increased when there were requirements for combinations of transformer voltages and where high-tension windings were to be tapped for regulating purposes. The terminals should be brought through porcelain insulators with the lower ends located beneath the level of the oil in the transformer. In the installation to which Mr. Mershon referred the terminals were brought through stuffing boxes in order to make the case air-tight. Mr. de Muralt said that in Europe the air-blast transformer is considered a greater fire risk than the oil-cooled transformer. The desirability of fire-proofing the buildings of electrical plants was illustrated by Mr. Lyford, who cited the fact that the only two buildings left intact in the Baltimore burned district were the new power house and sub-station of the electric company. Mr. Hazard suggested sealing the space above the oil in the transformer with an inert gas such as carbon dioxide supplied by a gas generator. One suggestion was that the oil used in transformers should have a fire test of approximately 400° F., and another that it should have a flash test not below 175° C., as in that case there would practically be no evaporation at 100° C. Mr. I. A. Taylor said that in the case of transformer terminals he had used a porcelain tube filled with sulphur, and he advocated that transformer cases should be adequately grounded to prevent fire and for personal safety. Marble terminal boards were generally criticised.

In the discussion on high-tension switches, Mr. Chesney, after classifying such switches into four types, concluded that the oil switch in the present state of the art is the only one to be used in high-tension work, and he laid down a number of requirements in connection with such switches. Dr. Perrine described some experiments with oil switches on the 40,000-volt line of the Standard Electric Company in California. The full load of four 2,000-kw machines was broken a number of times by such switches, in every case satisfactorily opening the circuits. Mr. Alex Dow favored oil over air switches. As to switching, he considered that while in some cases the conditions permit the running of everything on the same set of mains in multiple, the general condition, however, indicated their separation into groups. Mr. Mershon expressed the opinion that the oil switch is at least as reliable as the apparatus which it controls up to 10,000 volts, but he does not consider it necessarily a final development, since it is not yet entirely adapted to high-voltage work. Mr. Stott said he looked upon group switches in the light of an insurance against interruptions of service, which insurance had to be paid for in complication and first cost. Mr. Scott considered that the air switch still has a large field where the voltages are large and where the oil switch is expensive to install. Mr. P. N. Nunn said he could not defend the air switch as in the 40,000-volt Provo plant such switches are being displaced as rapidly as possible by oil switches. Mr. de Muralt favored the oil type switch, but considered the horn type of switch as applicable in special cases.

In the discussion on group switches, Mr. Stillwell said that if in a plant there should be three shut-downs in the course of a year from using single switches, it would be better to install group switches and eliminate the shut-downs entirely. Prof. D. C. Jackson criticised the arrangement of group switches described by Mr. Stillwell as being of limited usefulness, and said that an arrangement whereby individual circuits are brought directly to the main bus-bars is usually to be preferred. Mr. I. A. Taylor considered that the advantages enumerated for group switches might be more simply and cheaply obtained by the use of multi-point control switches used in parallel with the ordinary ones. Mr. Gilbert Wright was of the opinion that group switches and duplicate buses involve a cost much too large in proportion to the results obtained. Mr. John B. Taylor commented in detail upon the various considerations put forward by Mr. Stillwell concerning the use of group switches, his comment in general being adverse to use of the system except where the conditions specifically indicate its advantages. He advocated an arrangement which is essentially a single main bus-bar and a series of group buses, which may be interconnected to form a reserve main bus in case of trouble or to facilitate work upon the main bus.

Simultaneous Telephone and Telegraph Equipment.

By Le Roy W. Stanton.

The apparatus entering into the equipment of a modern long-distance telephone line includes not only special telephone apparatus, but also apparatus for making practical the use of the telegraph in connection with the telephone, so that simultaneous telegraphy and telephony may be accomplished.

The revenue derived from telegraph leases on long-distance telephone lines, in many cases equals, and quite often exceeds that derived from the long-distance telephone service. While this practice is not new, its application has not been extensive, owing to the meagre knowledge of the principles, and the limited number of

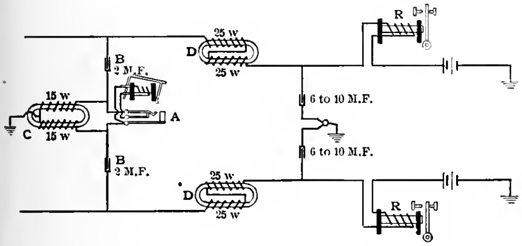


FIG. 1.—DIAGRAM OF COMBINATION CIRCUIT.

long-distance telephone lines. The successful operation of the system depends upon the proper proportion and arrangement of inductance and capacity. The effect of high and low-frequency currents upon impedance coils and condensers being directly opposite. The comparatively slow vibrations of the impulses in a telegraph circuit pass readily through the impedance coils, but are almost totally obstructed by the condensers, while on the other hand, the vibrations set up by the voice in the telephone transmitter, produce in the line a current of very high frequency, which has a directly opposite effect upon the condenser and impedance coils arranged in the circuit.

Fig. 1 shows diagrammatically the arrangement of the circuit where each side of the line is used as a separate telegraph circuit, and the two circuits or sides of the line form a metallic circuit for telephone purposes. *A* represents a telephone set, *B* a two-M.F.

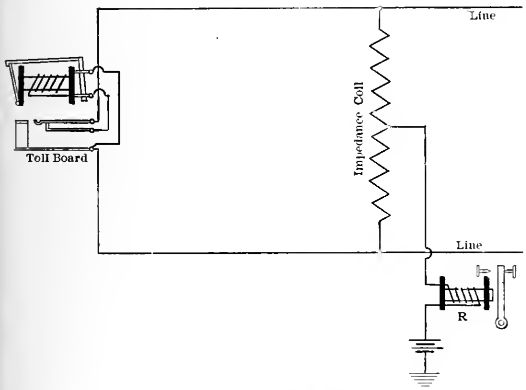

FIG. 2.—CIRCUIT WITH IMPEDANCE COIL.

condenser, *C* an impedance coil wound to 30 ohms. The coil is large and massive so as to have a high inductance. The core is composed of a complete iron circuit, and the windings are wound on two spools and so connected as to give the greatest impedance to voice currents, this being necessary, as the coil is bridged in parallel with the telephone set across the line; the function of the coil is to reduce the click from the telegraph circuit, caused by the opening and closing of the telegraph key, which produces a rise and fall of potential on the line, and tends to charge and discharge the condensers, which are in series with the telephone set across the line. This coil being grounded in the center allows the condensers to discharge to ground through one-half of the coil instead of through the telephone set to ground on the other side of the line.

If r represents the resistance of one-half of the coil, *C* and *L*, its inductance then to the slow discharge current from the condenser to the ground, due to the making and breaking of the telegraph circuit, its total impedance to ground will not much exceed its resistance, r, which in this case is 15 ohms. But the telephone current has a very high frequency, and owing to the high inductance of coil *C* almost the total telephone current passes through the telephone set. The total impedance to the voice currents through coil

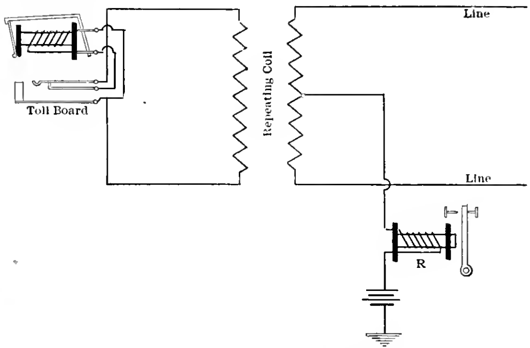

FIG. 3.—CIRCUIT WITH REPEATING COIL.

C may be expressed by the formula: Impedance $= \sqrt{R^2 + (2\pi\, n\, L)^2}$ in which n is the frequency and L the inductance. The average value of n is about 1,000. Taking the value of L at 10 henrys, the impedance $= \sqrt{30^2 + (2 \times 3.1416 \times 1{,}000 \times 10)^2} = 62{,}832$ ohms. In this case r (30 ohms) is so small compared to the reactance that it does not appreciably affect the result, 62,832 ohms, at all and could just as well be neglected. Coil *D* is similar to coil *C*, but is wound to 50 ohms. The two windings on this coil are connected so that the inductive reactance of the two coils oppose each other. This is very important, for it has been determined by trial that otherwise the self-induction from this coil in making and breaking the telegraph circuit causes a very perceptible click in the telephone.

Fig. 5 represents diagrammatically the form of the current wave when the telegraph current passes through a coil having a very high coefficient of self-induction. Upon the breaking of the telegraph circuit by the key, the potential instantly rises, which causes the high

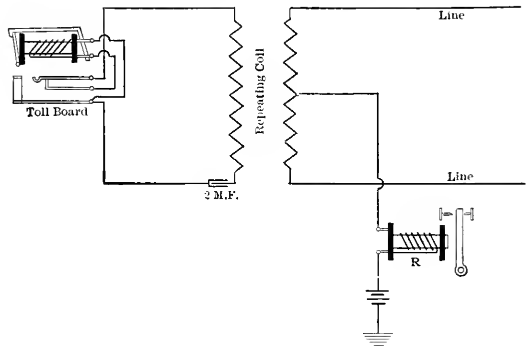

FIG. 4.—CIRCUIT WITH REPEATING COIL AND CONDENSER.

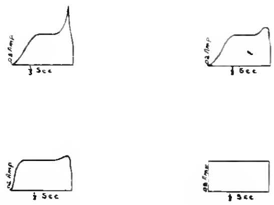
peak. This high instantaneous voltage is what produces the very severe click in the telephone set and very materially interferes with the use of the telephone. If the two windings of this coil are connected so that the inductive reactance of the coils neutralize each other, there is a very slight click in the telephone set and the lag in the telegraph circuit is very materially reduced. The sluggish working of telegraph instruments is very noticeable when there is a high inductance in the circuit of the telegraph sets. Fig. 6 represents the form of current wave when the coils are connected so as to neutralize each other. Fig. 7 illustrates diagrammatically the form of the current wave in an ordinary telegraph circuit in which the current rises almost instantly from zero to its maximum strength when the key is closed, and then remains constant or continuous about the duration of the signal and then falls suddenly to zero when the key is opened. Fig. 8 represents the form of current wave in a telegraph circuit in which there is no inductance or capacity.

While the inductive reactance of the two windings of coil D to the comparatively slow oscillation in the telegraph circuit tends to neutralize each other, owing to the neutralizing effect of the windings, it is not so with the high-frequency voice currents; for here the rate of oscillation is very high, and as a matter of fact the effect is comparatively the same, whether the coils are connected to neutralize each other or to give what would be expected to be the greatest inductive reactance.

The impedance of the coil to the telegraph current would not much, if at all, exceed its resistance. For the impedance =



FIGS. 5, 6, 7 AND 8.—FORMS OF CURRENT WAVES.

$\sqrt{R^2 + (2\pi n L)^2} = R$; since the current circulates in opposite directions through the two coils around the same iron core. If the windings were not exactly balanced, the impedance would be a little greater than R, but not much even then, because n is comparatively low, not over about 15 per second.

While the above is true of slowly changing currents, it does not apply to extreme high-frequency currents. The core of coil D forms a complete magnetic iron circuit, and is large and massive, which makes it sluggish. This prevents a complete reversal of its magnetism throughout the whole core when the very high-frequency telephone currents tend to reverse it; therefore, instead of one complete magentic circuit we have two. The lines of force set up in each coil find a return path through the air rather than through the iron; moreover, the two coils oppose each other inductively, which further tends to make each coil and its core act as an independent impedance coil. Such being the case, we have two similar impedance coils in series to oppose the telephone current. The impedance of the two coils in series is given by the formula:

$$\sqrt{(2R + 2R)^2 + (2\pi n L - 2\pi n L)^2} = \sqrt{(R)^2 + (4\pi n L)^2}.$$

The proper arrangement of condensers and their capacity is also

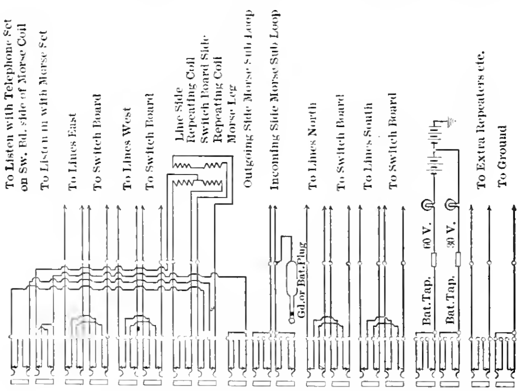


FIG. 9.—TEST PANEL USING REPEATING COIL FOR MORSE WORK.

quite important. The greater the capacity of a condenser within certain limits, the more efficient it becomes for transmitting speech. For this reason, a large capacity condenser would naturally suggest itself for use in series with the telephone set, which is bridged across the line. Experience has proven that if a large condenser is used in this connection, that it causes quite a perceptible disturbance from the telegraph in the telephone set, due to the fact that the greater the capacity of the condenser the larger the charge and discharge as the potential on the telegraph line rises and falls when the key is closed and opened. The larger charge and discharge currents flowing between the condenser and ground, produce, of course, a greater variation of potential in the circuit in which the receiver is connected. Thus the telephone receiver is interfered with if the capacities of the condensers B and B' are too large.

The condensers which are bridged to ground, between the im-

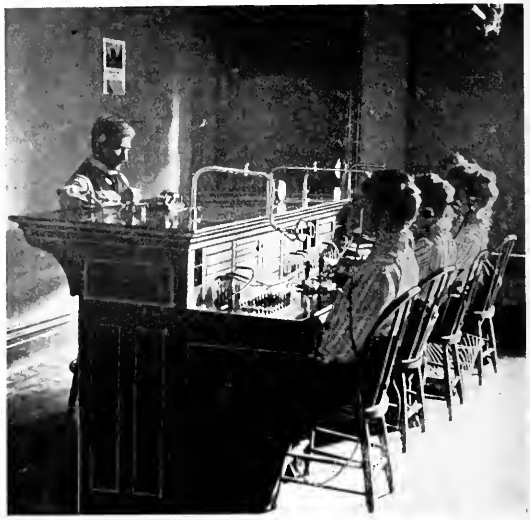

FIG. 11.—TICKET WIRE OPERATOR AND LONG-DISTANCE TELEPHONE OPERATORS.

pedance coils and telegraph instruments, should be from six (6) to ten (10) microfarads. The greater the capacity of these condensers, the less the disturbance in the telephone circuit from the telegraph.

It is sometimes advisable to bridge the telegraph key with a two (2)-microfarad condenser, which absorbs the sudden rise of potential due to the self-inductance of the line and coils when the circuit is broken by the key, thus preventing a sharp fluctuation on the line tending to cause a disturbance in the telephone set.

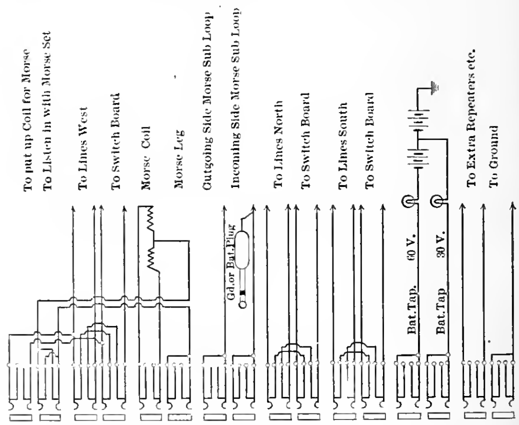

FIG. 10.—TEST PANEL USING IMPEDANCE COIL FOR MORSE WORK.

The above arrangements of circuits and apparatus gives a very satisfactory service, both from a telegraph and telephone standpoint, and admits of the use of a pair of wires for carrying on intelligence between three pairs of parties at the same time, without interference, which very materially increases the earning powers of a long-distance line. The principle disadvantage of the system is the difficulty of securing suitable signalling apparatus between the telephone operators. Signalling over a composited long-distance line in the ordinary way with telephone generator seriously interferes with the telegraph service and does not signal the distant telephone operator, owing to the comparatively low frequency of the regular generator, and the arrangement of the apparatus in the circuit.

60-cycle current is used, there is no interference to the telegraph service, and the signalling between telephone operators is positive if a properly designed line drop is used.

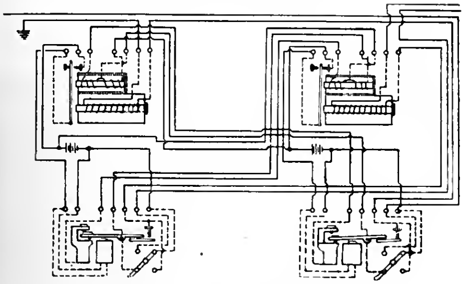

Fig. 12.—Wiring of Weiny-Phillips Repeater.

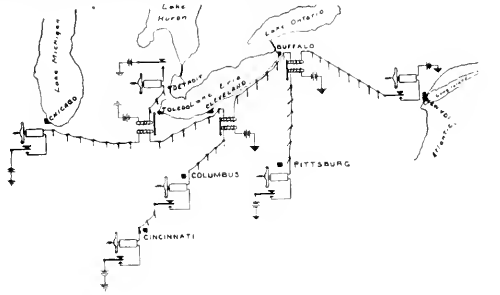

Fig. 13.—Diagram of Through Lines and Branches.

The slow alterations of the signalling generators are somewhat impeded by condensers B and B', and shunted from the line drop in the telephone set by coil C, which does not offer a very high impedance to a 16-cycle ringing current, but if a 133-cycle or even a

Within the past few months there has been installed on some of the long-distance lines apparatus that enables the ordinary ringing currents to be used; the ringing currents being passed through a vibrator, which in turn passes through a small transformer, the secondary of

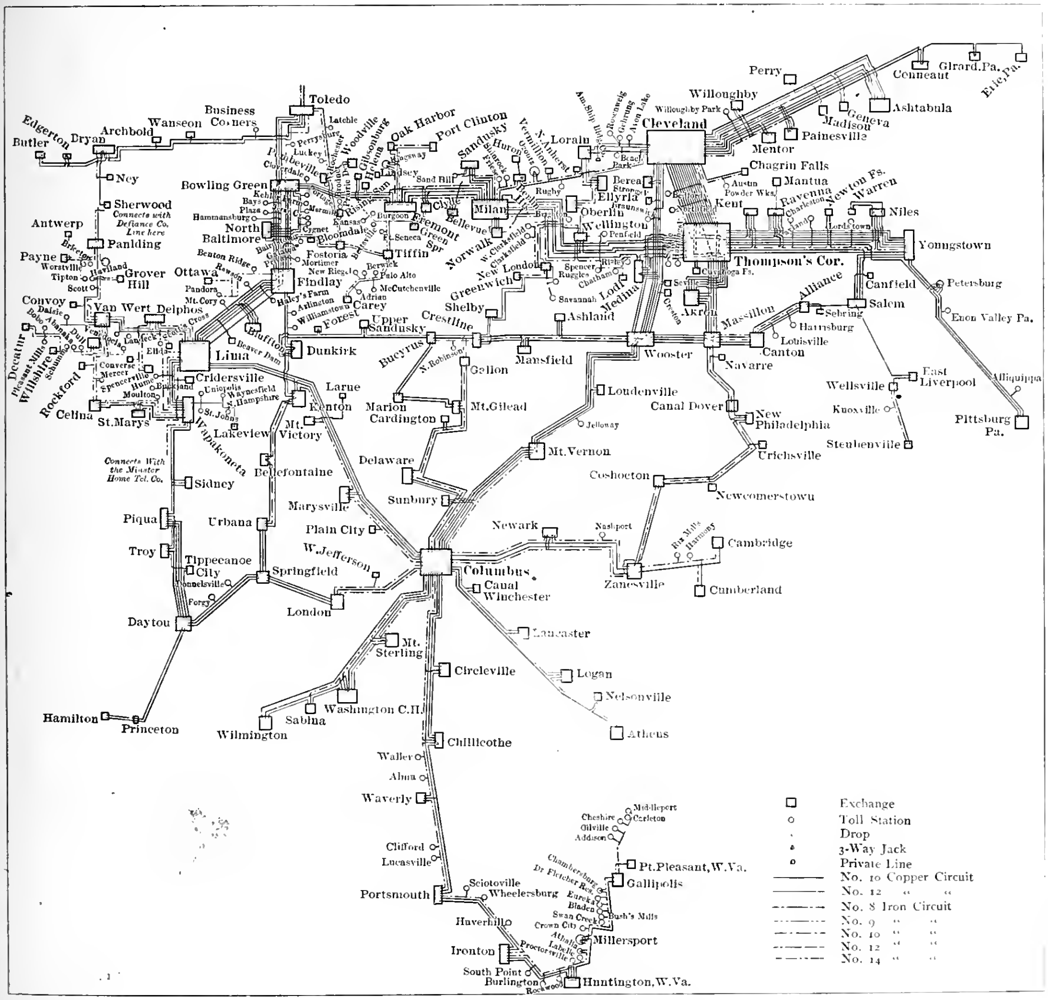

Fig. 14.—Circuit Map, United States Telephone Company.

which delivers to the line a comparatively high-frequency current, which operates a specially-designed relay, which in turn operates the line drop, thus signalling the operator at the distant station.

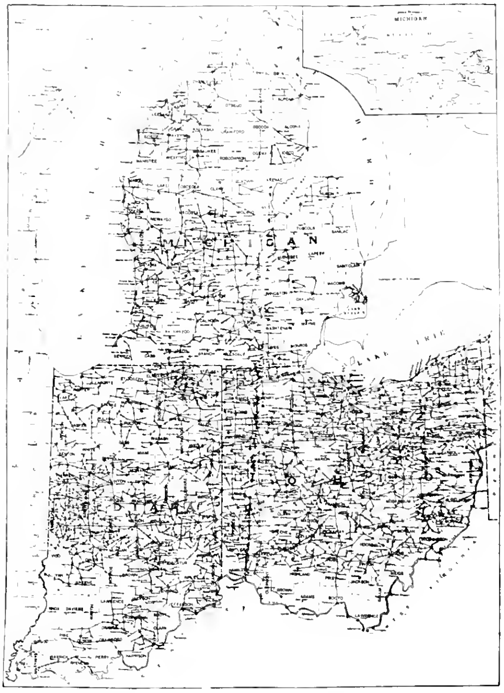

FIG. 15.—MAP OF TOLL LINES IN MICHIGAN, INDIANA AND OHIO.

The disadvantage of the high-frequency currents is that they tend to produce noise on the lines. When lines are composited, the telephone connections are usually ordered up by telegraph or order

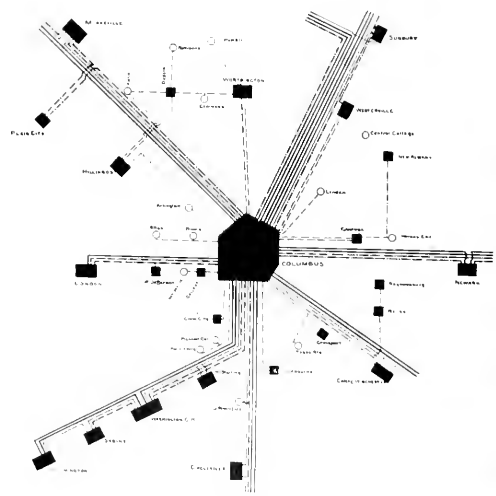

FIG. 16.—TROUBLE DISTRICT.

wire, most generally by the telegraph. Fig. 11 shows view of a ticket wire operator sitting at the rear of tollboard, making appointments and ordering up telephone connections by telegraph.

Fig. 2 shows another method of using a telephone line for telegraph purposes. This system possesses advantages as well as disadvantages over the one so far described. It is much cheaper to install, but it requires both sides of the line to make one telegraph circuit. It possesses, however, the advantage of the telephone operator being able to signal in the regular way without the use of special apparatus. The impedance coil, which is bridged across the line, has very low resistance, but high inductance, which prevents the voice currents from being short-circuited. The telegraph circuit being tapped in the center of the winding of the impedance coil, there is no inductance to oppose the telegraph current and to produce

FIG. 18.—REPEATER AND SWITCHING STATION, TOLEDO, OHIO.

a lag in the telegraph circuit, which tends to make the telegraph instruments act sluggish. The principal disadvantages of this system are: First, there can be but one telegraph circuit derived from each telephone circuit; second, the interference to the telegraph service by telephone operators signalling with ringing generators, which become accidentally grounded or which are permanently grounded. This trouble could be remedied by using a special generator at the terminus of the Morse lines, if it was not for the fact that the same circuit is often connected to other long-distance telephone lines, which extend to scores of other offices, any one of which, by ringing with a grounded generator, interferes with the telegraph service. A third objection is that unless condensers are used between the impedance coil and the terminus of the line on the tollboard, the Morse circuit is liable to become grounded, and interfere with the telegraph service by a telephone operator connecting this circuit with another long-distance line, which is accidentally grounded. The last two conditions can be eliminated by terminating the telephone lines, which are also used for Morse work on smaller size jacks on the tollboard, and using connecting cords, which have repeating coils in circuit, and which terminate on large

FIG. 17.—REPEATER AND SWITCHING STATION, THOMPSON'S CORNERS, O.

and small-sized plugs. This slightly interferes with the rapid handling of telephone traffic and cuts down the talking efficiency of the line, to some extent, but effectually prevents interference to the telegraph service.

Fig. 3 shows the use of a repeating coil for deriving a telegraph circuit from a telephone circuit. This system possesses the advantage of operators being able to signal each other with an ordinary generator, providing it has sufficient voltage and output, and there is no interference to the telegraph service in case the derived line is connected with a line which is grounded. The telephone service

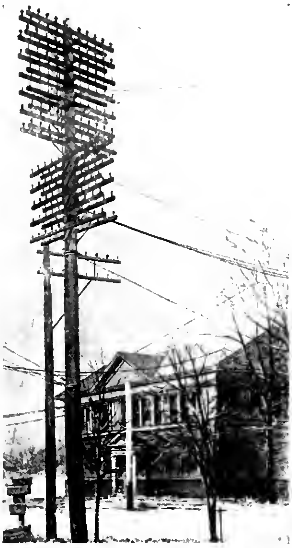

FIG. 19.—TERMINAL POLE SHOWING LEADS.

over this system is very inferior owing to the number of repeating coils which are liable to be used if the telephone circuit is of any great length and built up at a number of stations.

The repeating coils used in this system have to be specially designed so that they will transmit the ringing current, otherwise the telephone operators would not be able to signal each other. Such coils, while efficient for ringing purposes, are quite inferior for transmitting the voice currents, with their high frequencies.

The system also has the disadvantage of the telegraph service interfering with the telephone service. This is caused in three ways: First, if there is an escape caused by a slight ground on one side of the line, it causes a greater flow of the telegraph current through the winding of the repeating coil that is connected to the side of the line from which there is an escape. This allows the click of the telegraph to be heard in the telephone. Second, if one side of the line is of higher resistance than the other, which is always the case

FIG. 21.—TEMPORARY TEST PANEL, TOLEDO, OHIO.

to a greater or less extent, it causes an unequal division of the current which produces a disturbance, as above mentioned. The same disturbance is noticeable if the windings of the coils are not perfectly balanced.

The circuit illustrated in Fig. 4 is the same as Fig. 3, except that there is a 2 m.f. condenser in series wihh the coil leading to the toll-board. It has been found that a condenser so placed assists in throwing the line drop.

FIG. 20.—VIEW OF WIRE CHIEF'S ROOM, THOMPSON'S CORNERS, O., SHOWING REPEATER TABLES, TEST PANEL AND PORTION OF COIL RACK.

Figs. 9 and 10 represent diagrammatically the wiring of what is known as a Morse test panel. Fig. 9 represents the method of wiring where repeating coils are used, and Fig. 10 represents the method of wiring where impedance coils are used. Wiring for composite work is somewhat more complicated owing to the fact that each side of the line is used for a separate telegraph circuit. The wiring of these test panels must be such that great flexibility is secured in building up circuits and replacing breaks in a long line. If a New York-Chicago composite circuit gives trouble, the wire chiefs at the various switching stations along the line must be able to immediately locate the trouble and remedy same. The section which is in trouble will be located between two switching stations. This portion of the circuit must be discarded and another wire from some other circuit substituted without a moment's delay, as the telegraph circuits are kept busy by brokers and other classes of important business, in which a slight delay often means considerable loss. For to give a thoroughly reliable service the company should have several different leads throughout the country over which to route the business in case one lead wire was entirely broken down by a sleet storm, etc.

The test panels are equipped with instruments for making tests for locating trouble and listening in on telegraph lines to see if same are working properly. The wire chief must be able, by listening in with a telegraph instrument, to determine whether there is a swinging ground on the line, an escapement, insufficient battery, etc., and be able to remedy same without delay. (Morse wire chiefs become very expert in detecting the slightest trouble by listening to a Morse instrument.) The test panels are so wired that a line between New York and Chicago which is being used in sections for telephone work; for instance, between New York and Buffalo, parties may be carrying conversation over one section, Buffalo-Toledo parties using another section, and Detroit-Chicago parties using another section, and at the same time the entire line is being used as

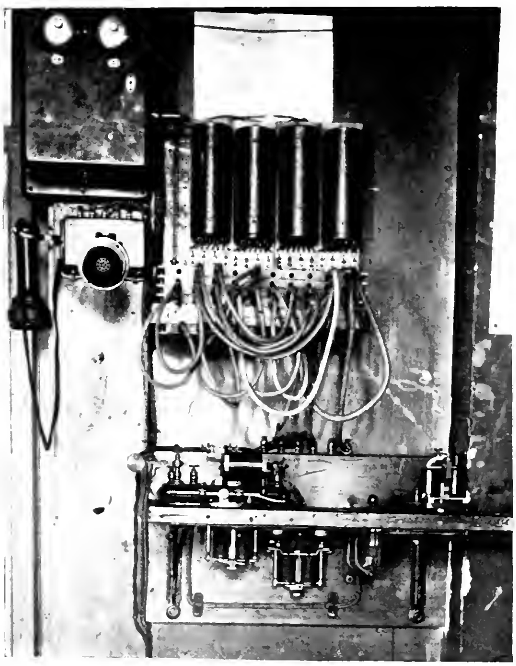

FIG. 22.—EQUIPMENT USED IN SMALL SWITCHING STATIONS.

one complete telegraph circuit. It is also practicable to use one side of one line in one section and another side of another line in another section to make up one complete telegraph circuit without interference in any way.

The test panel is also arranged so that any voltage which may be required up to 120 volts can be cut into any telegraph circuit. This is accomplished by the means of storage batteries located in the switching stations. Various voltages are used according to the distance between the stations and the number of instruments in circuit and the amount of leakage. However, with too high a voltage there is a greater liability of the telegraph interfering with the telephone. Arrangements are such on the test panels that repeaters can be cut in or out according to the requirements, and side line repeaters added, if necessary. The wiring of the Weiny-Phillips repeaters is shown in Fig. 12.

Fig. 13 shows diagrammatically a through line between two terminal points with branch lines taken off at intermediate cities. In

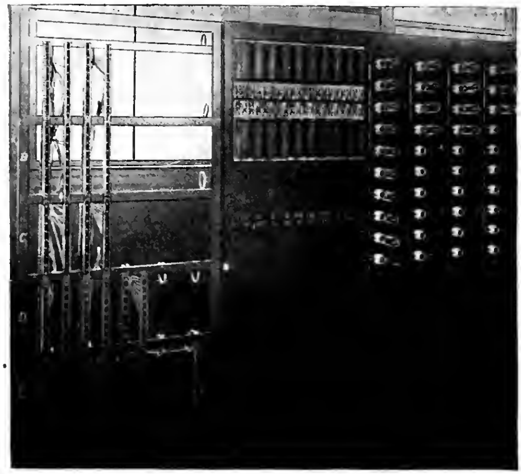

FIG. 23.—VIEW OF CROSS-CONNECTING RACK, MORSE COILS AND BATTERY RESISTANCE LAMPS.

newspaper work, for instance, between New York and Chicago, a number of cities not directly on the line, receive the service over a signal branch line from the main line, while the main line remains continuous. At the point where the branch is made, a side line repeater is used. If a loop was used double the mileage of wire would be necessary to serve the branch cities and in addition there would be added considerable impedance to the circuit and a greater liability to trouble, such as breaks, grounds, etc.

The geographical location of long-distance switching or repeater stations is a very important matter both from a telephone and telegraph standpoint, and from a point of economy in buildings, equipment, and in superintendance, they should be located at the same place. These stations should be located near and on direct lines between the large business centers and at distances from three to four hundred miles apart. From a telephone standpoint, it is much more economical to have the long-distance lines divided into sections, for instance from Chicago to New York or Boston, the line should be in sections; say, from Chicago to Toledo, from Toledo to near Buffalo, Buffalo to Albany, Albany to New York or Boston. If the telephone circuit was continuous, the company would be unable to receive as high earning powers from the line. By being divided into sections, each section is capable of transacting a toll business between intermediate cities when the line is not in use between the terminal points. This very materially increases the earning powers of the line. From a telegraph standpoint, it is quite often necessary that the line be continuous. Unlike the telephone, the telegraph is more efficient when repeaters are located every three or four hundred miles along the line. By means of automatic repeaters and separate sets of batteries for each section of the line, telegraphing is carried on more satisfactorily than when a continuous circuit is used. The earnings of long-distance lines are oftentimes more than doubled by being able to telegraph over the same line at the same time. The rental usually charged is $20 per mile per year for 12 hours' service and $30 per mile per year for 24 hours' service. The American (Bell) Telegraph & Telephone Company base the distance on which to charge on the railroad mileage. The Independent United States Telephone Company base their mileage distance on the air line distance between the cities receiving the service. The distance between New York and Chicago is approximately one thousand miles. At

$20 a mile per year the rental for one side of a telephone line for telegraph purposes would be $20,000. As a matter of fact, there are a number of telephone circuits between New York and Chicago for which brokers, newspaper companies and large business interests pay $18,000 a year for a single wire, which brings the earnings of a telephone circuit for telegraph use up to $36,000 per year. In addition to a very large toll earning from the use of the long-distance telephone, a telephone company is at very little additional expense when supplying telegraph service, or what is often termed leased wire service, as the parties who lease the service supply their own telegraph operators. The maintenance of the line is practically the same whether the telephone lines are used for telegraph purposes or not. The copper circuit furnished by long-distance telephone companies are much superior to the ordinary iron wire used by the telegraph companies. The United States Telephone Company, whose offices are in Cleveland, Ohio, has several thousand miles of long-distance telephone line, over which they are doing a very heavy simultaneous telegraph and telephone business, having leased lines to a number of brokers in Cleveland and other cities, such as Pittsburg, Pa.; Youngstown, Ohio, and Columbus, Ohio. Their lines also carry the bulk of telegraph work done by the Associated Press in Ohio, and some business for the Steel Corporation between Cleveland, Ohio; Pittsburg, Pa.; Wheeling, W. Va., etc., as well as for some of the coal mining companies. They have been successfully carrying on this line of work, now, for more than two years. The simultaneous telephone and telegraph equipment was put in operation by the writer while engineer for the United States Telephone Company.

Fig. 14 shows a circuit map of the United States Telephone Company's lines in Ohio. This territory is subdivided into districts over

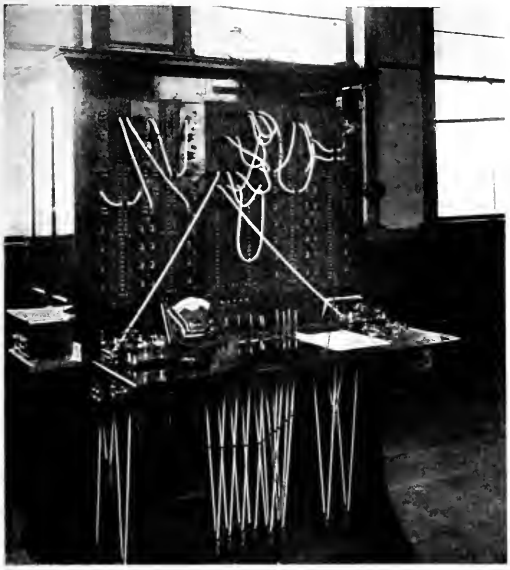

FIG. 24.—TEST PANEL, SHOWING METHOD OF BUILDING UP SIMULTANEOUS TELEPHONE AND TELEGRAPH CIRCUITS.

which the superintendent of that district is held responsible for the service of both telegraph and telephone equipment.

Fig. 15 is printed merely to indicate the density of toll line service operated by the various independent companies in Ohio, Indiana and Michigan. As a matter of fact, the network lacks many new lines. These lines are tributary to the United States Telephone Company's long-distance trunk lines. In the State of Ohio the United States Telephone Company now operate more than 19,000 miles of copper metallic circuit and is connected with 498 independent telephone exchanges, which operate more than 140,000 telephones and through the tributaries, such as various independent toll lines, reach 1,470 cities, villages, towns and hamlets in the State of Ohio. Fig. 16 is a map of the lines radiating from Columbus and illustrates how territories are mapped out for the various district superintendents.

A number of engravings are presented herewith, made from photographs in regard to features of the work. Fig. 17 is a view of the United States Telephone Company's repeater and switching station at Thompson's Corners, Ohio, and Fig. 18 of the repeater and switching station at Toledo, Ohio. Fig. 19 shows a terminal pole, with leads north, south and west. Fig. 20 illustrates the wire chief's room with repeater tables, test panel and a portion of the coil rack, Thompson's Corners. Fig. 21 shows a temporary test panel at Toledo, Ohio, and Fig. 22 shows the equipment used in small switching stations, in the wire chief's office of the local telephone company. Fig. 23 shows the cross-cennecting rack, Morse coils and bank of battery resistance lamps. Fig. 24 is a test panel and illustrates the method

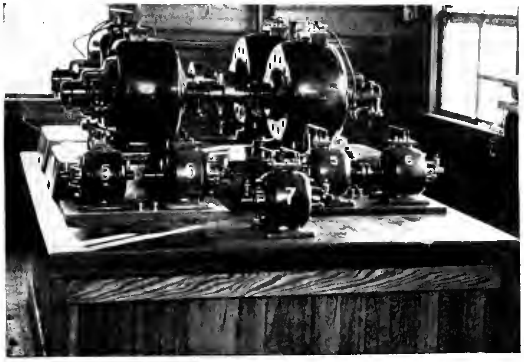

FIG. 25.—DUPLICATE SETS OF CHARGING AND RINGING MACHINES.

of building up simultaneous telegraph and telephone circuits. In Fig. 25 is seen an equipment of duplicate sets of charging and ringing machines. The generators are designed for charging storage batteries, for operating the systems as described above.

Within a short time the United States Telephone Company will be able to communicate with all the large cities of the central west, of the northwest, of the southwest and all the principal cities in the east except New York and Boston.

There is at the present time, with the exception of two breaks of 40 miles each, a solid copper metallic circuit of Nos. 8 and 10, from Topeka, Kan., to Atlantic City, connecting Topeka, Kansas City, St. Louis, Indianapolis, Columbus, Cleveland, Pittsburg, Baltimore and Philadelphia. Paralleling this, with the exception of two short breaks, is a solid copper metallic circuit connecting Albany, Syracuse, Buffalo, Cleveland, Toledo, Detroit and Grand Rapids.

With the building of less than 200 miles of line there will be a solid trunk line of copper metallic circuit connecting the northwest with the southwest, starting at Duluth, passing through Minneapolis and St. Paul, down the Mississippi River to La Crosse, Wis.; Dubuque, Iowa; St. Louis, Mo.; San Antonio and Galveston, Texas.

The Illinois Telegraph & Telephone Company is at the present time perfecting plans for joining the independent toll trunk lines of the central west with its large automatic exchange in Chicago. This will not only give switching facilities for the through trunk line systems, but will enable the independent telephone companies of the west to reach Chicago, which is their business center.

With the rapid consolidating of independent telephone properties that has been progressing for the past few years, we cannot but expect to see two great telephone companies competing for both telegraph and telephone business, which will eventually bring about a consolidation between one of the telephone companies and one of the telegraph companies. This may compel an alliance between the two remaining companies, for the telephone and telegraph companies combined can reduce operating expenses very materially. The same official staff, the same buildings, same conduit system, pole lines, etc., that is used by one can be used by the two; and many other decided economies could be effected and give a more effective and superior service.

Water Power Transmission Plant at Elliotts Falls, Ontario.

By Charles L. Fitch.

THE Province of Ontario, situated as it is, immediately contiguous to the populous and agriculturally active States of New York, Pennsylvania and Ohio, would long since have rivalled them in wealth and importance were it not for the fact that its soil, with the exception of a strip along the southern border, is to a great extent rocky and barren, yielding at best but meagre return to the labor of the farmer. Nature, however, as if to make amends for its niggardness in this respect, has provided an abundant supply of water; and the surface is dotted with myriads of lakes connected by innumerable small streams, forming indeed an almost unbroken chain from Hudson Bay on the north to Lake Ontario on the south.

These streams as a rule are quite small, their average flow in many cases being less than 200 cu. ft. per second; but though the volume of water is not large, in most cases it is quite constant, owing to the immense natural reservoirs in the lakes above which constitute the sources of supply. For this reason they are admirably adapted to the development of power, as their even flow not only insures that the full amount of power counted on will be obtainable every day in the year, but does away with the expensive construction so necessary in less favored localities to take care of floods.

As it has become patent to all that the poverty of the soil in this region has rendered farming but a thankless occupation, increasing attention is daily being given to industrial enterprises as a means of livelihood, and although development must necessarily be slow, owing to the—as yet—limited resources of the people, it is not beyond the bounds of belief that we shall one day see the Province of Ontario prospering as a manufacturing district supplying the vast market which will then be found in the great agricultural Northwest, which even now shows signs of its coming importance. In this development, the many water powers along the small streams with which the country abounds, will play no unimportant part.

FIG. 3.—THE FALLS.

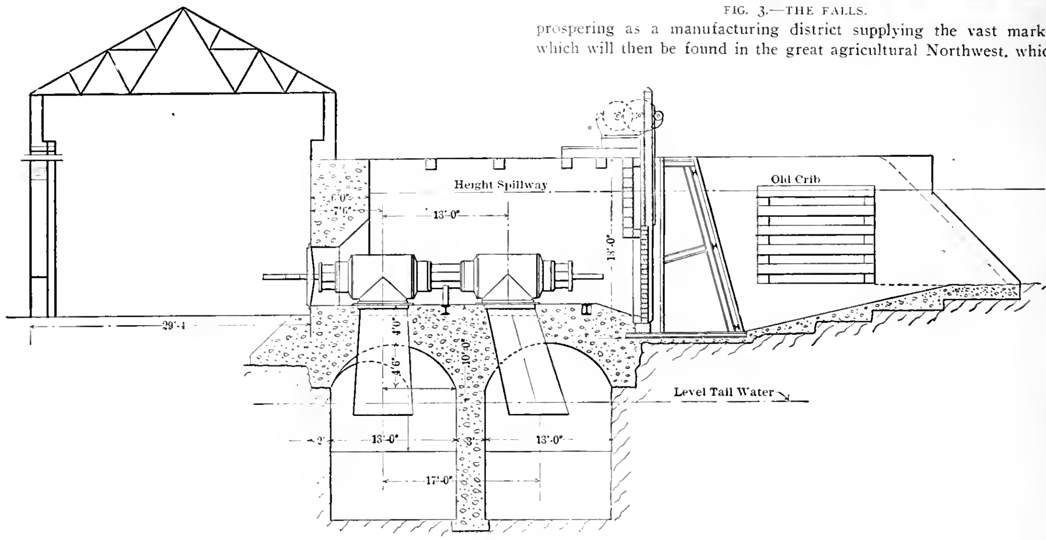

Fig 1.—Sectional Elevation of Generating Plant.

FIG. 2.—VIEW OF OLD DAM FROM BELOW.

Among the more recent enterprises set on foot in this section, not the least important is the cement works of the Raven Lake Portland Cement Company, a six-kiln plant of modern design located at Raven Lake, in Victoria County, about eighty miles north of Toronto on the Grand Trunk Railway. This manufactory, which will be ready for operation early in the coming summer, was designed by the well-known cement engineer, Robert F. Wentz, of Nazareth, Pa., and represents the most advanced ideas in the economic manufacture of cement. The marl forming one of the ingredients is to be dredged from the bottom of the lake, which covers a deposit of great depth, and the clay to make the mix will be brought in by rail from one of the near-by beds.

One of the most important considerations in an enterprise of this character is the power for operating the machinery and grinding the cement. This may be estimated at about 24 hp-hours per barrel of output; and when steam is used this item constitutes a very considerable factor in the cost of manufacture. Power for the Raven Lake enterprise will be obtained from Elliotts Falls, thirteen miles to the north, where a water power electric generating plant for the purpose is under construction; and it is with the development of power at this point that the present article will principally deal.

Elliotts Falls is on the Gull River, a small stream in one of the principal chains of lakes in this locality, which flowing south and east find their way eventually into Trent River and Lake Ontario. For many years the government has maintained a dam at this point, and a sluiceway to facilitate the "running" of logs, and the place was once the site of a small mill, which, however, utilized but little of the power available. The flowage of the river when last measured was somewhat under 600 second-feet, and the fall from the spillway of the dam to the surface of tail water when operations were commenced was about 17 ft.

After careful consideration, it was decided to raise the dam 18 in., and by blasting out a ridge in the river below. lower the tail-water 3 ft., giving a total head of 21½ ft. With these changes it was considered feasible to develop a maximum of 1,200 hp, and the work of designing the plant and supervising its construction was placed in the hands of the writer.

FIG. 4.—EXCAVATING THE TAIL-RACE.

Referring to the sketch map at the beginning of this article, showing the falls and their immediate surroundings, it will be seen that the river flows in a southerly direction, and just below the falls, expands into a sort of basin or lagoon lying somewhat west of the general course of the stream. The government works, most of which have been utilized, consisted of a wood dam at the top of the falls proper, and a timber crib connecting with it, extending up and down the stream and confining the water to the easterly channel. The dam is provided with a sluiceway at each end and extensive runways for the passage of logs.

The plan of development included a tail-race and wheel-pit to be blasted out of the solid granite rock formation just east of the crib referred to, and extending up from the lagoon below to a point about 50 ft. above the dam. This was then to be covered by arches of concrete masonry supporting the three wheel chambers, which were made to communicate with the river above the dam through the medium of a fore-bay, formed by removing a section of the crib and enclosing the space by concrete wing walls above and below. The dotted lines on the map show the relative location of the new work.

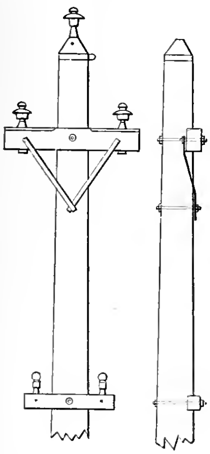

FIG. 5.—TRANSMISSION POLE.

The south wing wall was deflected at a right angle and carried down stream about 35 ft. to form the west wall of the sluiceway at the west end of the main dam, thus making it feasible at any future time to remove the main dam and replace it with a concrete structure without interrupting the continuous operation of the plant. The north wing wall was extended out 15 ft. beyond the up-stream face of the crib, which was heavily sheet-piled and reinforced by a puddle wall 3 ft. thick protected by a bank of gravel at a slope of one to one, riprapped with coarse broken stone.

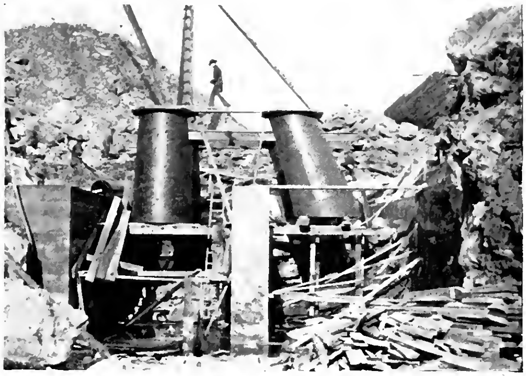

FIG. 6.—SETTING THE DRAFT TUBES.

As the main dam itself was very leaky, extensive repairs here were found necessary, but they will be only of a temporary nature, pending an entirely new structure in the near future.

In order to carry on the hydraulic work as above outlined, it was necessary to construct a coffer-dam from the west end of the spillway of the main dam to the west bank above the crib. The greatest depth of water found was about 7 ft., and the structure decided on was a cribwork of 10-in. x 12-in. hemlock sawed timber, 6 ft. wide on top, loaded with stone and sheet-piled with two layers of 1½-in. plank. This was found to answer the purpose satisfactorily

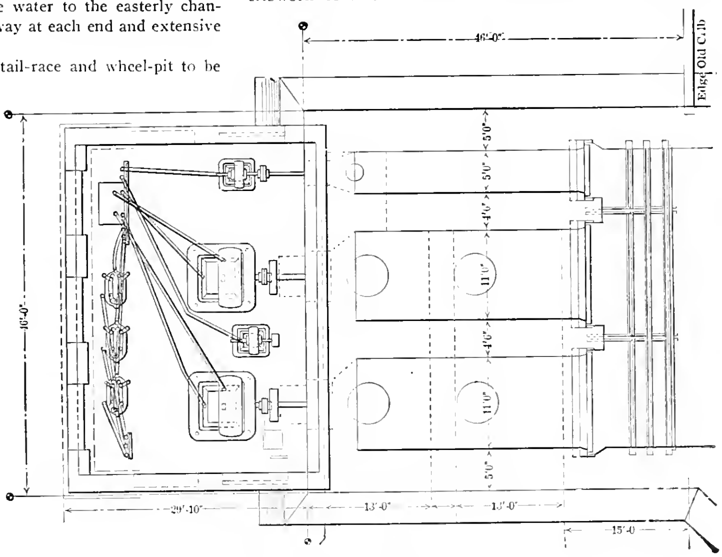

FIG. 7.—PLAN OF POWER HOUSE AND FOREBAY.

The excavation of the wheel-pit and tail-race was carried on with rock drills of Canadian manufacture. the work being commenced at the north end and extended in a southerly direction toward the lagoon; the final breaking through into the river being deferred until everything was completed in the wheel-pits, and the draught-tubes and masonry supporting them were in place. The separating ridge was then blasted out, letting the water in, the debris being removed by dredging. In this way the necessity of a coffer-dam below the falls was avoided.

The entire masonry structure was of concrete composed of Portland cement, sand and crushed stone in the proportions of 1, 2 and 5. The cement was of Canadian manufacture, and suitable sand and stone were obtained on the ground. The concrete was mixed by a Jeffrey spiral mixer.

As the necessity for early completion required that much of the masonry be put in place during the cold winter months, a temporary building framed of rough poles and sheathed with inch boards covered with tar paper was constructed over the entire work, and the interior was kept heated with stoves and steam coils to a temperature of not less than 40° F. day and night until completion. In this way the progress of the work was rendered independent of weather conditions.

The power house was constructed with concrete walls and a wood-sheathed felt roof supported on steel trusses. The general arrangement may be seen from the ground plan and section elevation shown herewith.

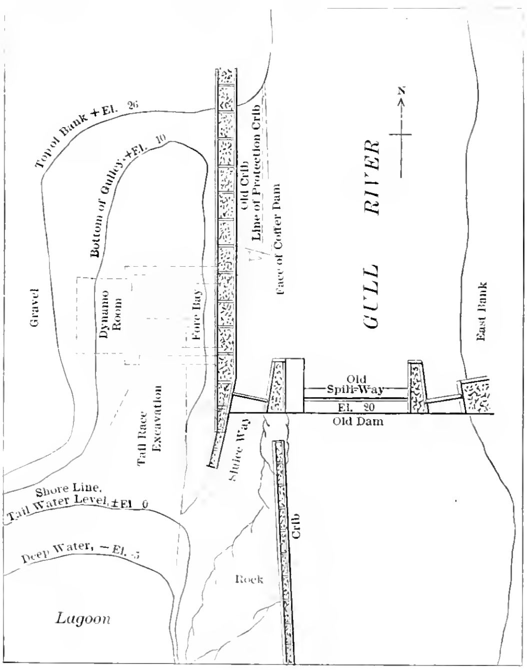

FIG. 8.—SKETCH MAP OF LOCATION.

The generating units, two in number, are each direct-driven by a bank of four 25-in. horizontal turbine wheels mounted on one shaft, which pierces the breast wall separating the wheel chambers from the dynamo room.

The turbines were furnished by the Jencks Machine Company, of Sherbrooke, Ontario, and each bank of four has an ultimate capacity at full head, of 600 hp on the wheel shaft. They are equipped with Woodward governors.

The generators have each a rated capacity of 350 kw and generate alternating current of 25 cycles. There are two exciters, each sufficient for the entire output of the station. One of them is designed to be belt-driven from the shaft of either of the main dynamos, while the other is provided with its own pair of turbines and is direct-driven.

The low-tension switchboard is of marble and is located at the north end of the building. It consists of a main panel, two generator panels, an exciter panel and a feeder panel, all equipped with the usual instruments and switches. The high-tension switchboard is of similar material and is placed at the south end of the room, the space between the two being occupied by the static transformers, which step the current up to 16,000 volts for transmission to Raven Lake. All wiring is carried in conduits placed beneath the concrete floor, and the station is protected by lightning arresters of the General Electric type. The entire electrical equipment was furnished by the Canadian General Electric Company.

The transmission line, between the generating station and the cement mill at Raven Lake, is supported on cedar poles, spaced 115 ft. apart. The general arrangement may be seen from Fig. —, representing a trimmed pole. Each pole has a single cross arm 4 in. x 6 in. of Georgia pine, with steel braces and Locke porcelain insulators. The conductors, three in number, of No. 2 aluminum cable, are carried, two on the cross arm and one on the peak, forming an equilateral triangle, 28 in. on a side. There is also a telephone circuit of two No. 12 galvanized iron wires, supported on a smaller cross arm placed 6 ft. below and transposed every 500 ft. Both the cross arms and the braces are bolted through the poles with galvanized bolts.

The poles vary in length from 30 ft. to 45 ft., being set to a profile, avoiding all abrupt changes in level; and the line runs partly along the public highways and partly over private property, keeping it as straight as possible.

At the Raven Lake end there is a masonry sub-station 25 ft. x 37 ft., in which are placed the static transformers which step the current down to 600 volts for use in the mill.

In this connection, it is interesting to note the strides forward which mark the present era in the history of our cousins across the border; and the case in point, where almost everything needed was obtained from native sources, is but a slight indication of the growth which has taken place in the last decade.

The Canadian is nothing if not conservative, and turns his back squarely on the bubble of inflation. Born of a self-reliant stock, he thinks well of his own judgment, but does not disdain the assistance of others. While making haste slowly, his progress is exceeding sure, and unmarred by the fiascos which have brought many to ruin. With a supreme confidence in the good-will of his fellow-men, he takes kindly to a new idea only when he has become satisfied that it will pay, but once satisfied he embraces it eagerly, subscribes to it as far as his means will permit, and works with a will to help it along. For these reasons his banks are secure and his shares generally pay dividends.

The Raven Lake Portland Cement Company is a Canadian institution having its headquarters at Toronto. John Lucas is its president and Thomas McLaughlin its secretary-treasurer, and to the untiring energy and devotion of these gentlemen may largely be traced the success which has attended the launching of this enterprise.

Cable War Messages.

A telegram to the newspaper press from Chicago of March 21 says: "Two Associated Press war bulletins raced from Yin-Kow to Chicago to-day, one by the European route and the other across the Pacific. The one from the east reached here at 11.12 o'clock, and the one from the west just eight minutes later. Both were filed at Yin-Kow to-day at 7.30 P.M. Each was about 100 words in length, and they were almost identical in matter. They were sent by different routes to test the rapidity of transmission. They were not censored or held up in any way en route." In this connection the *Chronicle*, of San Francisco, asserts that that city is now the center for the world of news from the Pacific.

N. E. L. A. Index.

A very comprehensive and much needed index of all the volumes of proceedings of the National Electric Light Association since its first convention is now in process of compilation. This work has been undertaken by Mr. T. H. Creden, who is not only one of the best statisticians in the electric lighting business, but is also a constructing and operating electrical engineer, having served in both capacities with the Chicago Edison Company and with Messrs. Stone and Webster. In giving his services for this work, Mr. Creden will deserve much gratitude from the members of the Association and others interested in the reports, as it now becomes an easy matter to find at once any topic or paper to which reference is desired. Until the book of the twenty-sixth convention was printed no attempt at a topical index has been made. It is the intention to have the complete index printed before the Boston meeting, to be held May 24, 25 and 26.

Electricity and the Law in England and America.

By W. Valentine Ball, Barrister-at-Law.

THERE is no subject which awakes a wider interest on both sides of the Atlantic than electricity. The extraordinary development of its varied uses in recent years, the facilities which it has afforded for locomotion and the transmission of messages, not to mention all the other multifarious needs of mankind which it serves, tend to give it the foremost place among those branches of modern science, which have been found capable of practical application.

Seeing that the application of electricity on a commercial scale is of comparatively recent growth, it is not surprising that the law which affects its generation and distribution is to be found in statutes passed and cases decided within the last few years. But the search, even when conducted by a lawyer in England, should not be confined to English statutes and law reports. If exhaustive treatment is required or an argument is to be pointed by references to a decided case, he must often refer to the work of American lawyers, for numerous interesting cases upon the laws of electricity have from time to time been decided in the courts of the various States of the Union.

It is to be observed, however, at the outset, that although English and American lawyers have advanced along the same lines in ascertaining the application of legal principles to the vagaries of electricity, the decisions in the one country can only be regarded as useful precedents by lawyers in the other. Further, the decisions in the various States of the Union are by no means uniform, nor does it appear that the opinion of a judge in one State is binding upon that of his judicial brother in another State. Nevertheless, the general principles—with which it is my object to deal in the present article, may, broadly speaking, be taken to apply not only in England and America, but throughout the countries which are inhabited by English-speaking races.

In England, the manufacture and supply of electricity to consumers is an industry in which any private person may indulge without legal restriction, so long as he complies with the ordinary law relating to nuisance and negligence. In view, however, of the difficulties attendant upon the laying of wires and mains across private and public property, and the necessity of allowing electrical companies to have power to break up roads, etc., for this purpose, certain acts have been passed under the provisions of which the supply may be carried out under powers which impose upon each company the duty of supplying every consumer in its district on equal terms. Of these, an act passed in 1882, is the most important, and one of its provisions is worthy of particular attention, *e. g.*, Section 17, which provides that in the exercise of the powers in relation to the execution of works given them under the act, or any license, order or special act, the undertakers shall cause as little detriment and inconvenience and do as little damage as may be, and shall make full compensation to all bodies and persons interested for all damage sustained by them by reason or in consequence of the exercise of such powers, the amount and application of such compensation in case of difference to be determined by arbitration. This clause makes it plain that the company cannot plead their parliamentary powers in answer to an action for damage caused by them in the execution of their works.

Their liabilities are further declared by another provision which forms part and parcel of every order under which they work, and which provides that nothing shall exonerate electric lighting undertakers from any indictment, action or other proceedings for nuisance in the event of any nuisance being caused by them.

The effect of these sections is that they are subject to what is known in England as the common law. There is nothing which better illustrates the adaptibility of the English law to the needs of the public than the way in which the legal questions incidental to the supply of electricity are found to be solved in so far as they are not dealt with in special statutes by the recognized principles underlying the leading cases decided by English judges in days gone by

It is proposed to deal here with the liabilities of supply companies under the heads of (1) negligence and (2) nuisance.

There are many ways in which a supply company may be guilty of negligence. At the generating station itself perpetual care has to be taken that the apparatus is in such order that employees shall not be exposed to unnecessary risk. Heavy machinery involves danger to those who are employed to work it, while men employed around dynamos and at a switchboard are constantly exposed to the risk of electric shocks. Accidents at generating stations give rise to claims for compensation under the Workmen's Compensation Act, 1897, and the other acts which render employers liable to pay damages for injuries which are caused by their negligence in permitting the use of defective machinery, or employing persons whose negligence occasions injury to their fellow servants. As questions of this kind are of common occurrence and are determined upon principles which apply to all actions for personal injuries, it is not necessary for our present purpose to discuss them further.

I pass on to consider the question of liability for accidents which may arise during the transmission of electricity. Dealing first with electric lighting companies, it is necessary to point out that for the purpose of their undertaking they usually require to lay their lines overhead or underground along public streets. The Electric Lighting Acts, subject to any special modifications which may be introduced in favor of any particular company, confer upon the undertakers the right to exercise the power, subject to their making compensation for any damage or injury which they may occasion to any property interfered with. In the case of overhead wires, attachments may have to be made to houses or private property along the roadway, or to posts erected on the street itself. Again, when wires are laid underground, it is often necessary for the lighting company who wish to lay their wires to remove temporarily water pipes or gas pipes which may be in the way. In all these cases the company is liable for negligence.

But the liability of the company does not end with construction of works. They are also bound to make good any damage which may be occasioned to the public by falling wires, escape of current and electric shock. If we may refer to a case which has to do with electric traction, in a case which was heard some years ago, it was proved that a wire which was fully charged, fell upon and killed a horse. The Court held the company liable. But where, in another case, the damage was caused by a telephone wire falling on a trolley wire and so earthing the return current, it was held that inasmuch as the falling of the telephone wire was the proximate cause of the accident, the electric supply company was not liable. It was held in that case that the injury was really caused by the negligence of the telephone company in allowing its wire to get into such a state of repair that it broke and fell. It follows from this that if a wire were to break and do damage to private property of any kind, the electrical company might be held responsible.

No liability, however, will be incurred in respect of damage which results from an act specially authorized by statute, or which is the necessary consequence of what is so authorized; but for this exception to apply, the power specified by the statute must be strictly adhered to, and if a choice exists as to the manner in which the powers may be exercised, due regard must be had to the individuals or the public affected by the exercise of the powers.[1] Hence if we may again borrow an illustration from the law relating to tramways, if a company has authority to conduct electricity along naked wires or rails, it will not generally be liable for any injury to a person coming into contact with them, nor will it be liable for any injury caused by the accidental breaking of a wire or rail merely by reason of such breakage. Where there is negligence on the part of the company, however —as if wires are allowed to sag so as to be within reach of persons passing along the street—the company will be liable for injuries arising out of such negligence, and in such cases the burden of proving negligence is not on the person claiming damages. In a case from Cape Colony[2] the defendants were owners of a telegraph wire and poles, which they had erected along a street under proper authority. A boy passing along the street either touched accidentally or took hold of a wire hanging from a pole, and his right hand was seriously injured by the electric current. It was given in evidence that the day before the accident the wire was hanging slack within the reach of passers-by, and this had been duly reported by a lineman to his superiors, and that the wires were usually inspected every four days. The company was held responsible. It was urged on behalf of the company that the plaintiff had been guilty of contributory negligence, but the Court held that there was a distinction to be observed between contributory negligence in a child and in a man.

---

[1] Seward Brice on Tramways, 1902.

[2] *Kift v. Town Council of Cape Town*, 1 South African L. J. (1901) 181.

Cases of negligence decided in the American and Canadian Courts are exceedingly useful to English lawyers. The effect of these cases is admirably stated in Mr. Robertson's work on "Tramways and Light Railways," 1903, p. 240. Thus, with regard to the care required from owners of electric apparatus, it has been decided that such care should be in proportion to the dangers which it is their duty to avoid, although, as was decided in the case of Perham v. Portland General Electric Company,[3] they are not bound to have perfect apparatus or construction. In another case it was held that a company who have wires and poles in the streets are bound to maintain such poles properly, but are not liable for subsequent defects which inspection would not reveal.[4]

In placing a pole near existing electric apparatus they are bound to take due measures to avoid contact, and to inspect from time to time, in order to keep their apparatus in suitable condition with reference to the previously existing apparatus. Mr. Robertson also deduces the following statement of law from American cases: "Generally, the grant of the privilege to encumber the highway with dangerous electric apparatus imposes a duty not to injure persons lawfully on the highway, and to make the highway substantially as safe for them as it was before, and also to consider the safety of persons, such as workmen, whose employment will naturally bring them into proximity with such apparatus. A storm, which is the immediate cause of the accident, is no excuse where there is such a want of care, but it may be, where there has been reasonable care, and the storm is an extraordinary one."

The case of Royal Electric Company v. Heir (21 *Can. Law Times*, 442, 1901), which was decided by the Court of Appeal of Quebec, well illustrates the obligation of a company contracting to supply electricity. In this case the plaintiff claimed damages for the death of her husband (to whose house the defendant company supplied electricity for lighting purposes) caused by his taking hold of an electric lamp (supplied by the defendant company in the ordinary course of their business) with the intention of turning on the light. The precise cause of the accident was not proved, but it was suggested by the Company that it was due to contact between the wire supplied by them with a guy wire of another company's system. Damages were awarded to the plaintiff and an appeal by the company was dismissed, the Court holding that there was negligence on the part of the company, and that the burden of proof of the fact, act or omission constituting negligence was not on the plaintiff.

The cases above referred to are drawn without discrimination from American, English and Colonial Law Reports, as so far as the law of negligence is concerned the judiciary of both countries appears to rely upon similar principles.

With regard to nuisances, it is important to again refer to the provisions of Section 17. It provides, as we have seen, that the undertakers are to do as little damage as may be. It follows that if and in so far as they do more damage than is necessary, or use a process which is (1) not the best known process, or (2) an unapproved process, they are, to that extent, common tort feasors, and amenable to the ordinary law, as well as to any statutory penalties and liabilities which may be imposed.

In dealing with the legal liability for nuisance much that has been said with regard to negligence has to be carefully borne in mind. A nuisance, however, may be created as incidental to the manufacture and supply of electricity. In these circumstances how far is the supply company to be held responsible? In the English case of *The National Telephone Company v. Baker*[5] a tramway was worked on the overhead trolley system. The current, after traversing the trolley wire and the car, returned by the rails and an uninsulated copper conductor running under the roadway parallel to the rails and connected with each rail. The telephones of the plaintiff company were worked on the single wire system with an earth return. The consequence was that the telephones were rendered practically useless, and the company claimed an injunction to restrain the defendant from using tramways so as to be a nuisance to or interfere with their telephones. The Judge who tried the case was inclined to decide in favor of the telephone company, but was prevented from doing so by the fact that the tramway company were protected from actions of this kind by their private act. In coming to the conclusion that the tramway company would have been liable if not so protected, he was guided by the decision in the famous case of *Fletcher v. Rylands*, where it was held that "The person who for his own purposes brings on to his land and keeps there anything likely to do mischief, if it escapes, must keep it at his peril, and, if he does not do so is *prima facie* answerable for all the damage which is the natural consequence of its escape. He can excuse himself by showing that the escape was due to the plaintiff's default; or perhaps that the escape was the consequence of *vis major*, or the act of God."

It is somewhat doubtful whether this principle can be properly applied to the use of electricity. If a man who makes use of delicate electrical apparatus were entitled to prevent a tramway or electric lighting company from doing anything which may affect his instruments, the progress of electricity in its application to great undertakings would be wholly arrested. The doctrine of *Fletcher v. Rylands* protects a man in the natural use of his property, and it cannot be said that the employment of delicate instruments is a natural use. Of course, the provisions of a particular tramway act may deprive him of his remedy; but it is submitted that wholly independent of statute law a telephone or telegraph company could not succeed.

A recent case in the Privy Council, which came before that august tribunal on appeal from the High Court of Cape Colony would seem to support the view that *Fletcher v. Rylands* must not be pressed too far in connection with electricity. In that case an action was brought by a telegraph company against a tramway company for interference by induction. In deciding for the tramway company, Lord Robertson said: "The appellants cannot claim higher privileges than other owners of land, and cannot create for themselves, by reason of the peculiarity of their trade apparatus, a higher right to limit the operations of their neighbors than belongs to ordinary owners of land who do not trade with telegraph cables." It is true that this decision was based not upon English law but upon Cape Dutch law; but it is important to notice that the sound principle which underlies it has long been adopted in the United States. In the case of *Cumberland Telephone and Telegraph Company v. United Electric Railway Company*[6] it was held that a telephone company could not restrain an electric railway company where the escape of electricity from the wires of the railway company was incidental to the conduct of their business, and where the telephone company could protect itself at much less expense than would be incurred by the railway company in preventing the escape of electricity. It may therefore be assumed that in future English judges will administer the law as it has been laid down in the Capetown Tramway case.

Further, the principle there laid down is consistent with what is usually recognized as a correct statement of the law of nuisance in England. Thus, Mr. Garrett, in his work on the law of nuisances, states: "If the owner of land uses it for any purpose which from its character may be called non-natural user, such, as for example, the introduction on to the land of something which in the natural condition of the land is not upon it, he does so at his peril, and is liable if sensible damage results to his neighbor's land, or if the latter's legitimate enjoyment of his land is thereby materially curtailed."

It might also be mentioned that a telephone company cannot claim any monopoly in the use of the earth for the purposes of return currents. At least the law has been so decided in a number of American cases that a telephone company has no vested interest in or exclusive right to the use of the "ground circuit" or "earth return" as against an electric street railway authorized by statute.[7]

Thawing Out Pipes.

Writing us on the subject of frozen water pipes, Mr. W. M. Bell, of the Conshohocken Electric Light & Power Company, of Conshohocken, Pa., says: "I beg to inform you that we have thawed out frozen service pipes and water mains by electric current, using a 10-kw transformer and taking from 75 to 160 amp. at 110 volts and not failing to start water running in from 3 to 45 minutes. The service water pipes are, as a rule, ½-in., ¾-in. and 1-in. pipe; also ½-in. lead pipes, and the mains thawed out were 1½-in., 2-in. and 2½-in., thawing at one time 2½-in. pipe about 450 ft. long in 45 minutes. This has been done in every instance without digging, connections being made at house of owner or on fire plug. We charge $5 a service, and have found it very profitable work. This work was carried out under my supervision, as superintendent of the company, and is the first done in this section."

The Shielded Balance.

By G. A. Campbell.

Experience shows that an ordinary balance when employed with an alternating current of the order of 2,000 cycles per second is variable and indefinite. It is the purpose of this article to show how this source of error may be entirely eliminated by shielding.

The difficulty encountered lies mainly in the direct capacity between the different parts of the system. Since the ether permits the flow of alternating currents in all directions, the attempt to employ an ordinary balance for alternating measurements is much the same as the attempt to measure resistance with a Wheatstone bridge immersed in a conducting fluid, such as acidulated water. In general a movement of the observer will change the distribution of the capacity effect and will change the adjustment required for a balance. Since it is necessary that the observer make certain movements in order to adjust the apparatus for a balance, this is a serious difficulty. Again, the entire generator circuit and connections form a part of the system, and any change in their capacity or leakage may affect the adjustment required for a balance. In case the generator is run from a lighting circuit, there is, of course, a direct capacity from the alternating-current side of the generator circuit to the lighting circuit, and this introduces the entire lighting system into the balance.

Even although the capacity of the entire system were kept invariable, there would be the difficulty that its distribution could not be determined. Thus, there may be direct capacity bridged between any number of points of the balance. This is illustrated in Fig. 1, where condensers are drawn in to illustrate this effect. Ex-

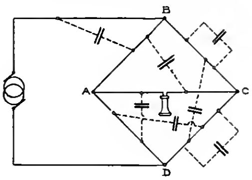

FIG. 1.

perience has shown and theory confirmed the fact that, with telephonic frequencies and impedances, these capacities are sufficient to cause large errors in the balance measurements.

As an example, take a balance having ratio arms of 1,000 ohms each, coils of .25 henry and 10 ohms effective resistance in the other arms and a frequency of 1,592 cycles per second, making $p = 10{,}000$. Then 100 micro-microfarads shunted around one ratio arm will introduce an error of 2.5 ohms, i. e., 25 per cent. in the effective resistance of the coil. The error varies as the square of the frequency and thus amounts to 100 per cent. at a frequency of 3184 cycles per second.

It is impracticable to isolate the different parts of the balance sufficiently to reduce these capacities to a negligible amount. The only practical way is to shield the different parts of the balance from each other and from any outside sources of disturbance.

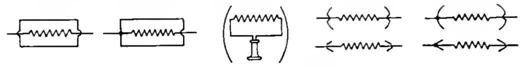
Shields may be divided into three classes, namely, 1°, magnetic; 2°, leakage, and 3°, capacity.

Magnetic shields are most advantageously made of thick iron castings. For alternating-current work they may also be made of masses of any conducting material, but iron seems to be the most efficient, considering its low cost and high permeability. In any case an efficient magnetic shield requires a large amount of material. Fortunately, the greater part of the apparatus does not require magnetic shielding. In resistances and condensers the magnetic field is very weak, and by winding inductance coils and transformers in toroidal form their external field can be made quite small. In the case of such inductance standards as have a large stray field, it is undesirable to introduce a magnetic shield on account of the difficulty of avoiding dissipative losses. Such standards must be put at a distance from other apparatus so as to avoid mutual disturbance. It is my expectation that inductance standards can be made toroidal in the future, so that the apparatus for standard alternating-current work can be used without magnetic shielding.

Leakage and capacity shields must ordinarily surround one of the two systems to be mutually shielded. Since it is usually a comparatively small capacity and leakage which is to be cut off by the shield, it is not necessary that the shields should have a small impedance. They may thus be as thin as is convenient to handle, and of any conducting material. While it is not necessary to keep the resistance of the shield small, it is desirable that the shield be so arranged that the flow of current in it shall be as direct as possible. In case the shield were spiral enclosing an iron core, the inductance of the shield circuit might be sufficient to make trouble, even although the resistance was negligible.

Fig. 2 shows diagrammatically a resistance coil with a shield entirely surrounding the coil, with the exception of two terminals. This shield is not connected to the coil and may be called a *floating* shield. Fig. 3 shows the same arrangement with the shield connected directly to one of the terminals of the resistance. This may be called a *connected* shield.

In case these shields have capacity to any other part of the system, it is evident that, with the connected shield, this capacity is



FIGS. 2, 3, 4, 5 AND 6.

definitely localized and terminates on one terminal of the resistance. It is also evident that, in the case of the floating shield, the capacity is not in general localized on any one part of the resistance, for the current to the shield will divide and a part will reach every part of the resistance which is exposed to the floating shield. In general, a floating shield is of use only when it entirely surrounds a system or a portion of a system connected only by mutual inductance with the remainder of the system. In other cases a connected shield is necessary if it is to shield one portion of a system from another portion of a system.

It is convenient to adopt a symbol for shields, since it is confusing to indicate them upon a diagram in case they form an extensive system. Figs. 4 and 6 show a symbol which I would suggest, the idea being that parentheses enclosing a network or any portion of a network represent a shield surrounding that much of the network. In case the terminals project through the shield they are shown projecting through the parentheses. In case the shield is short-circuited to one of the terminals of the network that is shown by a dot connecting the proper parenthesis with the terminal. It is to be understood that the parentheses are electrically connected. The parenthesis may degenerate into an arrow head for convenience. When several shields are employed, brackets, braces and quotation marks may be introduced. By designating shields by letters, as *S*, *S'*, *S''*, . . . their connection may be shown in the same conventional way as a ground connection. See Figs. 7 and 13.

Fig. 7 shows a shielded balance. Each of the six branches has its individual shield, which is connected to one of its terminals, and

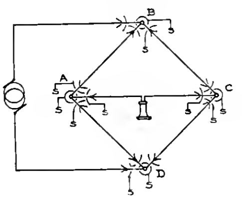


FIG. 7.

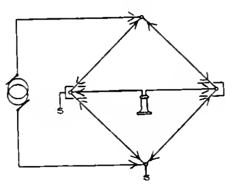

FIG. 8.

the entire balance is surrounded by a shield which is shown floating. The six terminals to which the six individual shields are connected may be disposed with respect to the four corners of the bridge in any one of the possible ways. To each of the four corners individual shields may be connected or one of the corners may have no individual shield connected to it, as shown in Fig. 7, corner *C*. The floating shield may be directly connected to any one of the four corners of the bridge. If the connection were made to a corner, such as *D*, where three of the individual shields terminate, as is shown in Fig. 7, then a material reduction in the complexity of the system would result, for three of the branches would be reduced to a single shield, and only the remaining three branches would have a double shield. In fact, but one double shield would be absolutely necessary, for, if the telephone circuit has a double shield, it does not make any material difference whether a leakage or capacity is shunted from terminal B to terminal D, provided it is not so large as to introduce serious shunting and does not contain an alternating e.m.f. and is not fluctuating rapidly itself. This arrangement is shown in Fig. 8.

Returning to Fig. 7, if the capacities of the corners to the floating shield are C_A, C_B, C_C, C_D, as shown in Fig. 9, then the equivalent set of direct capacities, C_1, C_2, C_3, C_4, between the bridge corners is:

$$C_1 = C_A C_B / (C_A + C_B + C_C + C_D)$$
$$C_2 = C_B C_C / (C_A + C_B + C_C + C_D)$$
$$C_3 = C_C C_D / (C_A + C_B + C_C + C_D)$$
$$C_4 = C_D C_A / (C_A + C_B + C_C + C_D)$$

If the impedances inserted directly between the corners are Z_1, Z_2, Z_3, Z_4, the condition for a balance is:

$$\frac{Z_1}{1 + Z_1 C_1 pi} \cdot \frac{Z_3}{1 + Z_3 C_3 pi} = \frac{Z_2}{1 + Z_2 C_2 pi} \cdot \frac{Z_4}{1 + Z_4 C_4 pi}$$

This makes the balance perfectly definite. The formulæ show that there is an advantage in leaving the outside shield floating, as this reduces the effect of any slight error in the determination of the capacity of the bridge corners to the floating shield.

In case an adjusting condenser is provided, the capacity to the floating shield may be so proportioned as to be eliminated in the equation for a balance. Thus: If Z_1, Z_2 are the bridge arms which are to be kept constant during a series of measurements, by making $C_A / C_C = Z_2/Z_1$, this condition is fulfilled. This may always be accomplished by adding a capacity at A or C, as the case may be, and balancing with Z_3 and Z_4 removed. It is, of course, necessary to consider the conductances as well as the capacity, and to balance this requires an adjustable leakage. Of course, the same balancing and elimination of the capacity may be carried out if the shield, S, is connected to the corner, D, which is necessary in a large class of work.

It is evident that there is in the preceding no limitation to equality ratios. Inequality ratios may be employed, and in fact the two ratio arms need not be of the same character. For instance, one might be resistance while the other was capacity.

Expressed in terms of the four admittances, Y_1, Y_2, Y_3, Y_4, directly connecting the four corners of the balance and the four admittances, Y_A, Y_B, Y_C, Y_D, directly connecting the four corners of the balance with the shield, S, the general condition for a balance is:

$$\left(Y_1 + \frac{Y_A \cdot Y_B}{Y_A + Y_B + Y_C + Y_D}\right)\left(Y_3 + \frac{Y_C\, Y_D}{Y_A + Y_B + Y_C + Y_D}\right)$$
$$= \left(Y_2 + \frac{Y_B\, Y_C}{Y_A + Y_B + Y_C + Y_D}\right)\left(Y_4 + \frac{Y_D\, Y_A}{Y_A + Y_B + Y_C + Y_D}\right)$$

If none of the eight admittances vanish or are infinite, a balance might be obtained by suitably adjusting any one of the eight.

In case the admittance of corner B to the shield is equal to zero, the ratio of the balance will be equal to Y_2/Y_1, irrespective of the other admittances to the shield, S.

In case $Y_C / Y_A = Y_2/Y_1$, the ratio of the balance will be independent of the admittances of corners B and D to the shield S.

In case either pair of diagonally opposite corners is shielded from S, the balance is independent of the capacity of the two remaining corners to the outside shield, S.

In case $Y_B = 0$, and $Y_D = Y_A + Y_C$, the potential of the shields when a balance is obtained will be half-way between the common potential of C and A and the potential of D.

The shielded balance shown in Fig. 7 has a double shield entirely surrounding the generator system and another double shield entirely surrounding the telephone circuit, telephone and observer. One or the other of these shields may, as explained above, be reduced to a single shield. Even as thus simplified, however, the arrangement is not in general convenient. It is not practicable to shield a generator which is connected directly to a lighting plant, and it is not convenient to shield an observer. In order to avoid these difficulties, we may introduce transformers into both the generator circuit and the telephone circuit.

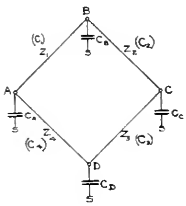

FIG. 9.

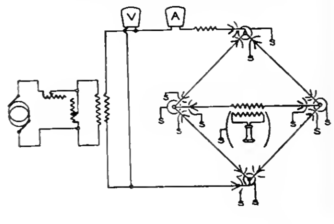

FIG. 10.

Fig. 10 shows an arrangement of shielded balance with two transformers. This balance leaves the generator, generator circuit and observer entirely unshielded, and is a perfectly practicable arrangement. Any change whatever in the generator circuit or the generator circuit transformer can have no effect upon the integrity of the balance so long as the shielding remains perfect. Thus, the generator may become grounded to the outside shield, either side of the repeating coil may become short-circuited to the shield surrounding it, or any number of convolutions may become short-circuited. These changes may affect the efficiency of the generator circuit, but can in no way introduce an error into the balance. The same is true of the telephone circuit. So long as the telephone is shielded as shown, any changes in itself or in its transformer will affect only its efficiency. It cannot introduce a false balance. Furthermore, the observer may change his position and his capacity and leakage to the outside shield and to the generator and generator circuit without in any way affecting the integrity of the balance.

FIG. 11.

Fig. 10 shows, in addition to the balance, the rheostats for varying the e.m.f., and the voltmeter and ammeter for measuring the current employed, all properly shielded. This shielding precludes any disturbance of the balance.

In case two impedances are to be placed in series in any branch of the balance, each may have its individual shield connected to one of the bridge corners. See Fig. 12, where the inductometer and resistances are arranged in this way.

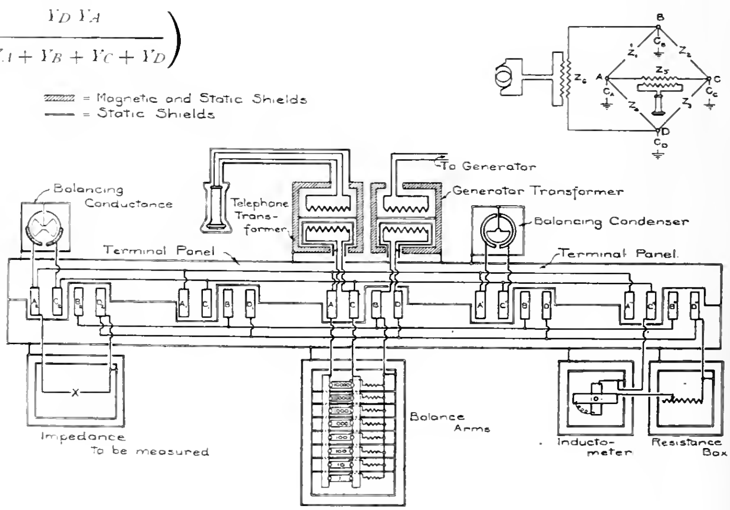

FIG. 12.—DIAGRAM OF SHIELDED BALANCE.

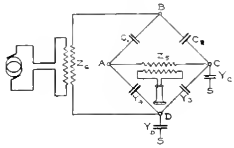
In case three impedances are to be connected in series, at least three courses are open. We may measure the capacity of the individual shields to the general shield and allow the proper correction.

We may so adjust the capacities, C_A, C_B, C_C, C_D, as to make the potential of the outer shield the same as that of the third shield. In general this would necessitate the use of considerable conductance and possibly inductance. Finally, we may shield the third shield by enclosing it within one of the others, and allow for the capacity thus directly shunted around one of the impedances. This use of shields within shields seems to be of considerable practical importance, and will be taken up again in connection with resistances and with switches. It is illustrated in Figs. 11 and 13.



Figs. 12 and 13 show more in detail two arrangements

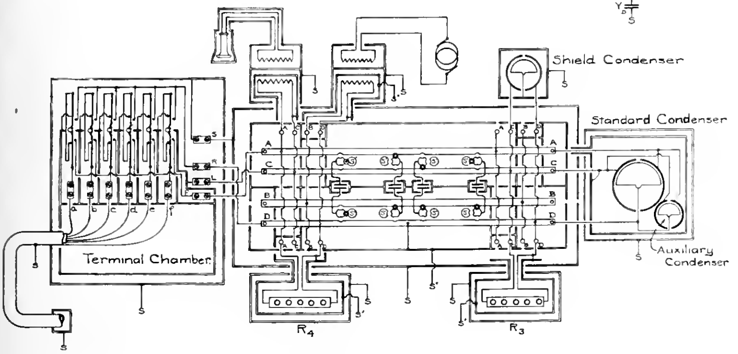


FIG. 13.—DIAGRAM OF SHIELDED BALANCE.

for shielded balances. Fig. 12 is arranged for inductance measurements and Fig. 13 for capacity measurements, but either may be employed for both measurements. Each arrangement presents certain practical advantages. The practical details of design will be reserved for description after they have been more completely tested by actual experience.

To summarize:

1. The balance arms are shielded individually and collectively in order to make the balance invariable and definite.

2. Shielded transformers are introduced into the generator and telephone branches in order to make the arrangement practicable.

3. The bridge corners are suitably shielded or their admittances to the outside shield suitably proportioned in order to make the numerical computations simple.

Important Electric Railway Tests at St. Louis.

Among the most valuable technical features of the St. Louis Exposition will be the elaborate series of electric railway tests which will be conducted there under the auspices of a special commission appointed by the Exposition authorities. The personnel of the Electric Railway Test Commission has already been announced in this paper, and consists of J. G. White, New York, chairman; H. H. Vreeland, New York; W. J. Wilgus, New York; James H. McGraw, New York, and George F. McCulloch, Indianapolis.

On the grounds of the Exposition the authorities will provide special tracks, having an almost level grade and well ballasted, for the operation and testing of railway car and locomotive equipments. These special tracks consist of one section, 1,400 ft. in length, and one section 2,000 ft. in length, the two sections being parallel. Upon these tracks it is proposed to carry on the greater part of the operating, acceleration, braking, coasting and motor-heating tests, as well as tests to determine car and train friction.

In addition to the trials which will be conducted on these tracks, as detailed above, the commission will carry on a number of tests in the Electricity Building. All of these tests will be supervised by some engineer of national reputation, to be selected later, and all instruments and appliances used in connection with them will be calibrated by the National Bureau of Standards. The latter bureau will erect in the Palace of Electricity a laboratory for this purpose, equipped with all appliances needed for the accurate standardization of all the instruments, meters, etc., required. Before deciding upon the detailed tests to be made, the Test Commission appointed four engineering committees to draw up a series of recommendations of the various tests, which, in their opinion, would cover the main branches of electric railway work as at present developed. These committees were as follows: Engineering Committee on Test of City and Suburban Equipments—M. G. Starrett, chief engineer, New York City Railway Company; D. F. Carver, chief engineer Public Service Corporation, of Jersey City; W. S. Twining, chief engineer Philadelphia Rapid Transit Company. Engineering Committee on Test of Interurban Equipments—A. L. Drum, assistant general manager Indiana Union Traction Company; Chas. Jones, chief engineer Elgin, Aurora & Chicago Railway; C. A. Alderman, chief engineer Appleyard System, Springfield, Ohio. Engineering Committee on Test of Heavy Traction Equipments—F. J. Sprague, New York City; Bion J. Arnold, New York City; W. J. Wilgus, New York Central & Hudson River Railroad, New York City; F. R. Slater, assistant engineer to L. B. Stillwell, New York City. Engineering Committee on New Electric Railway Systems—Bion J. Arnold, New York City; Paul M. Lincoln, Westinghouse Electric & Manufacturing Company, New York City; W. B. Potter, General Electric Company, Schenectady, N. Y.

The following are briefly the tests which have been recommended by the first two of these committees, and which have tentatively been adopted by the commission. The digest of the tests in the departments of heavy traction equipments and new electric railway systems will be published is an early issue.

The tests on apparatus in the Electricity Building suggested are as follows:

1. Tests of various kinds of electric railway motor equipments under constant load, regulated by brake, to determine rate of heating (*a*) of the armature, (*b*) of the field coils.

2. Tests of electric railway motor equipments of the various kinds, to determine the motor efficiency under different fixed conditions of operation, including varying number of stops per mile.

3. Tests on motor equipments to determine their torque curves and accelerating power.

4. Tests on electric railway motor equipments under constant loads, to determine the rheostatic losses corresponding to various lengths of time consumed in application of full-current strength.

5. Tests on electric railway motor equipments to determine at what loads, speeds and frequency of stops it becomes economical to adopt automatic control in place of hand control for single cars.

6. Tests of hand, automatic and multiple-control systems to determine their relative economy, certainty and regularity of starting motor car equipments under fixed conditions of load and track.

7. Tests of electric railway motor equipments to determine safe load during continuous operation, as compared with rated capacity of motors.

The tests on the experimental track are as follows:

8. Tests to determine the relative values of two-motor and four-motor car equipments (*a*) as to power consumption with fixed loads, and with varying loads; and (*b*) as to acceleration with both fixed and varying loads.

9. Tests to determine the proper method of mounting a two-motor equipment on an eight-wheel, two-truck car, viz.: on which two of the four axles shall the motors be mounted?

10. Acceleration tests on single cars and on motor cars and trailer, showing rate of acceleration and power used with both hand and automatic control.

11. Comparative tests on different types of power brakes, both electric and mechanical, in respect to efficiency and economy.

12. Braking tests on single car and on motor car with trailer, under varying conditions, with both hand and power brakes.

13. Tests on single car equipments to determine motor and truck friction at different speeds.

For tests on storage battery cars the following are recommended:

14. Tests to determine the efficiency of batteries under maximum, average and varying loads; also

15. Tests to determine life of batteries under average and adverse conditions of service.

The tests on apparatus to be conducted in the Electricity Building for interurban equipment are largely the same as those recommended for city equipment. For the experimental tracks the committee has recommended a series of tests with various classes of cars and equipments, provided time will permit. If only one type of equipment is tested the committee suggests a car body weighing 16 tons to 20 tons, exclusive of trucks and motors, with a pair of trucks weighing 8 tons to 12 tons per pair and a standard four-motor equipment of 75-hp motors, equipped with different types of hand and train controlling apparatus.

The three points to which effort will chiefly be directed, in case facilities for conducting high-speed tests are available, are as follows:

1. The relation between the average electrical losses in the motors and the rise in temperature attained under various conditions of high-speed service.

2. The train resistance (or power required to propel a car or train at uniform speed) at very high speeds.

3. The performance of cars equipped with controllers so arranged that the acceleration is automatic, as compared with the performance under similar conditions, where the rate of acceleration depends upon the handling of the controller by the motorman.

In the test on electrical losses an effort will be made to determine, of course, the average losses at different schedule speeds with a given rise in temperature and with different periods of stops and lay-overs.

The train resistance tests recommended are with single cars, and also with trains made up of different numbers of cars at various speeds, from 40 miles per hour upwards, and measured in different ways, viz.: by direct measurement of instantaneous power input when running at uniform speed, and by the coasting method.

In the test of control systems it is proposed to investigate not only the efficiency of different systems of control, but the effect of automatic acceleration on the power consumption, etc.

Cables for Electric Light and Power.[1]

The current issue of the *Electric Club Journal* prints a lecture delivered by Mr. H. W. Buck February 29 before the Electric Club, of Wilkinsburg, entitled "The Installation of Electric Cables," in which the subject is considered from the standpoint of electric light and power work. In opening Mr. Buck said that if statistics were compiled it would be found that more shut-downs of electric power plants had their rise in cable trouble than from any other cause—not troubles which could be blamed upon the cable manufacturer for defects in construction, but ones which are directly attributable to dangerous methods of installation. Referring to lead-covered cables, he says that these should not be used in a power house except in places where protection against water is required. The lead sheath being necessarily grounded makes the cable vulnerable to puncture from ground throughout its entire length, which danger does not exist in a braided cable. On account of the softness of lead, it serves as a very poor guard against mechanical injury. If a lead-covered cable is struck the grounded lead is very likely to be driven through the insulation to copper, and the cable is put out of business. Braid-covered rubber cables are not exposed to this risk. As a protection against fire, a lead covering is useless, for the lead melts at a very low temperature, and exposes the inflammable insulating compound to ignition. When once started, a lead-covered cable will support its own combustion until completely destroyed.

In high-voltage work a single-conductor lead-covered cable is especially objectionable. Static discharges seem to take place through the insulation to the lead, which rapidly injures the insulation—especially rubber—and a break-down soon follows. I have known a number of instances where such single-conductor cables have withstood a test of three times normal voltage and have broken down at normal voltage a few hours after being put in service. These breakdowns occur usually near the ends of the cable. In multiple-conductor cables this action does not seem to occur, the static activity probably being neutralized.

The present practice of putting cables in ducts as a protection from fire is condemned. As a general proposition, especially in high-voltage work, the best way to wire a power house is to use braided rubber insulated wire, supported in free air upon porcelain or other insulators which in themselves have sufficient insulation to withstand the operating voltage of the cable. The rubber insulation then serves only as a safeguard to life in case of momentary contact, and to prevent a short-circuit in case of temporarily lying tools or such things upon the cables. Cables should be spread out as far as possible from each other, in order to obtain the best possible ventilation and to minimize trouble in case of short-circuit.

Attention is called to the fact that the temperature of the outside of a cable does not indicate its maximum temperature. Some experiments made at Niagara by Mr. H. W. Fisher show that there may be a difference as high as 40° C. between the outside of the cable and the inside of the insulation. For this reason cables should have their outside temperature kept lower than is ordinarily the case. In laying out a cable system the matter of ventilation should, therefore, be regarded as of prime importance. The following method of fire-proofing cables, which is employed by the Niagara Falls Power Company, was given:

Asbestos strip, about 3 in. wide and 3/16 in. thick, is soaked in a silicate of soda solution until it is thoroughly impregnated. It is then, while soft, wrapped spirally around each cable, which has been put in place on its rack in the subway. This covering very quickly hardens and forms a coating like stone over the braid of the cable, which is fire-proof. Asbestos applied in this way has many advantages. It needs no binding wire or steel bands to hold it in place around the cable, which are apt to uncoil when most needed, for the silicate serves as a firm bond. Furthermore, the asbestos, having its pores entirely filled, becomes a good conductor of heat, and the heat from the copper losses can get out by conduction. Dry asbestos, on the other hand, in a porous, cloth-like condition, is a good insulator of heat, which is likely to subject the insulation of the cable wrapped with it to a high temperature. The method described has been given severe fire tests, and it has served its purpose in every case.

In underground cable work the lead covering is absolutely necessary for cable protection on account of water, and also because paper cables must be used for reasons of economy, and all cables must be drawn into ducts underground, for any form of subway with bracket supports for the cable would be prohibitive in cost. The objection to the single-conductor lead-covered cables still holds for underground use for voltages over 5,000. Such high-voltage conductors should, if possible, be placed in the form of multiple-conductor cables, where breakdown in insulation from static effects is seldom experienced if liberal-sized bells are used at the terminals of the cable.

Cable ducts should never be grouped more than two in width, in order that every duct may have an outlet for heat conduction through the surrounding earth. The heating in ducts should not exceed three watts per duct-foot for copper loss in the cable. In conduits built of insulating material, such as vitrified clay, little trouble need be feared from electrolysis if the conduit is well drained and dry. If the ducts, however, contain water and the cables are partially submerged, the lead covering will rapidly disintegrate, unless the sheath is bonded at frequent intervals to the nearest railway return circuit.

Where single-conductor lead-covered cables are used in underground installations for carrying large alternating currents at low voltage, trouble from induced current in the lead sheath should be guarded against. This does not refer to local eddies, but to the current which flows in the lead sheath of two parallel cables as secondary induced by the current in the copper of the same cables as primary. When the lead circuit is closed at two manholes by contact with supporting iron brackets the current which flows in the lead is very considerable, and the resulting loss is nearly equal to the I^2R loss in the copper, even at 25 cycles. At higher frequencies this loss will probably be greater. As a specific example some readings were cited which were taken on two parallel 300-ft. length of 1,250,000-cm. cable carrying 800 amp. in the copper at 25 cycles. The open-circuit voltage induced in the lead was 15 volts, and with the lead sheaths short-circuited at one end through an ammeter, the current was found to be approximately 200 amp. These figures indicate that the matter is one of the greatest importance, and special precautions should be taken in all underground work to meet it. The lead sheaths of all cables should be either bonded together carefully in every manhole or else carefully insulated. If neither one thing nor the other is done, sparking will occur from this lead current at the cable supports at the manholes, which will burn through the lead sheaths and cause a break-down.

The Economy of Reciprocating Engines at Light Loads as Compared With That of Steam Turbines.

BY J. A. SEYMOUR.

A NUMBER of articles have been recently published giving comparisons between the steam consumption of turbines and reciprocating engines, in which a relatively poor economy for reciprocating engines at light loads is assumed. This assumption is unwarranted by the actual performance of these engines. Whatever advantages in actual commercial use the steam turbine may ultimately prove to possess, there are no indications at the present time that among these advantages will be a better sustained economy at light loads than with the reciprocating engine. It is true that "the usual" or "average" rate of steam consumption of reciprocating engines at light loads is excessive, as compared with the full-load economy, but the usual or average reciprocating engine is really an uneconomical and out-of-date machine. The ideal reciprocating engine working with non-conducting cylinder walls, without loss from leakage, cylinder condensation or radiation, should expand to back pressure to secure greatest economy. To expand to back pressure in an actual engine would load it much below its most economical point. It follows that since a modern engine of economical type, having a much lower rate of steam consumption at full load, approaches more nearly the ideal engine than the above-mentioned average engine, it should effect proportionately a still greater saving at light loads; that is, it should have a flatter economy curve. In actual practice this is found to be true.

It is manifestly proper that a steam turbine should be compared, as regards economy at light loads, as well as at full load, only with an engine of some economical type which fairly represents the best practice of the present time, and also that in computing the difference between electrical and indicated horse-power readings the combined efficiency of a well-designed, up-to-date unit, should be assumed. The well-sustained economy at light loads of a reciprocating engine is well illustrated in Fig. 1, in which are plotted economy

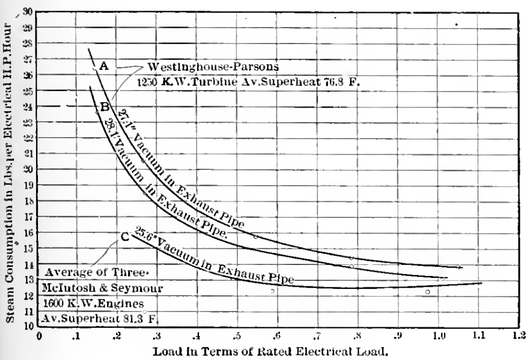

FIG. 1.—ECONOMY AT DIFFERENT LOADS.

curves in terms of electrical horse-power obtained from the results of a shop test of a 1,250-kw Westinghouse-Parsons turbine, described in an article by Mr. A. M. Mattice in the ELECTRICAL WORLD AND ENGINEER for February 20, and also the results of acceptance tests of three 1,600-kw McIntosh & Seymour engines referred to in a paper by Messrs. Moultrop and Curtiss, presented at the Boston meeting (May, 1902) of the American Society of Mechanical Engineers, published in Vol. XXIII of the transactions of that society.

Each engine is of the vertical cross-compound type, with a direct-driven 1,600-kw, direct-current generator of the General Electric Company make, and runs at a speed of 100 r.p.m. The cylinders are 29-in. and 60-in. in diameter, with a stroke of 56 in., and the engine, as is usual with this make, is provided with an interheating receiver which superheated the steam entering the low-pressure cylinder during the test from 55° F. to 69° F. The steam condensed in the jackets and heating coils in the receiver is included in the rates of steam consumption given. As stated by Messrs. Moultrop and Curtiss, no troubles have been occasioned by the use of superheated steam with these engines, although of standard construction throughout, which is true in all power stations where these engines have been used with superheated steam.

The economy curve, *C*, represents the average results of all tests made with superheated steam and with receiver heating coils in use upon engines No. 9, No. 10 and No. 11 in the station. The tests of engine No. 8 are excluded on account of conditions which prevented the correct economy of the engine from being ascertained. The best results obtained (with engine No. 9) are also indicated.

It should be understood that these were not shop tests made by the builders under ideal conditions, securing results not obtainable later in actual service, but were acceptance tests instituted by the purchaser to determine upon the fulfillment of contract conditions made at different times under actual working conditions after the engines had been from four to seven months in regular service. All instruments used for taking observations in the tests were accurately calibrated for each test, including the special instruments, used in the tests only, for taking electrical readings. The results were quite consistent for all three engines, the two tests indicated for engine No. 9 showing a greater variation from the average curve than any other test. The average results of tests obtained in such a manner from three engines should be unusually accurate and reliable. The conditions of steam pressure, superheat, etc., also correspond quite closely to those of the turbine tests except that the average vacuum was not nearly as good.

The nominal full-load rating of these engines, on the basis of 165 pounds gauge pressure at the throttle valve and 27-in. vacuum in the exhaust pipe, corresponds to 22/100 cut-off in the high pressure, or approximately to 19½ expansions by volume. The governor allows a maximum cut-off of over 7/10 in the high-pressure cylinder, which permits of a large working overload. It will be noted not only that the economy curve for the reciprocating engine shows a better result at light loads, but also that the point of greatest economy is more favorably located than for the turbine. Central station managers will hardly consider it practical to run steam turbines at their most economical loads without a greater overload capacity than it is proposed to give them, where the station load is a fluctuating one. At times of maximum station load it quite often happens that the steam pressure and vacuum fall off and the loss of pressure in the pipes, etc., increases so that the actual maximum output of the unit under these conditions may fall short of the nominal overload capacity under normal conditions to a serious extent. In the case of a turbine a very high vacuum is necessary in order to maintain either its capacity or its economy. To secure this high vacuum, particularly under heavy overloads and in warm weather, with condensing apparatus of a commercially practicable size, in most locations, will be an extremely difficult problem, a much more difficult problem than is generally understood, but one which will have to be met.

Additional data concerning both the turbine and engine tests for half and full loads are tabulated in the accompanying table. The results given for the turbine at half load with 28-in. vacuum are estimated, no test being reported. These data include the British thermal units per indicated horse-power per minute, and the ratios of the actual thermal efficiency to the efficiency of a corresponding ideal engine working on the Rankine cycle recommended as a standard of comparison by the Institution of Civil Engineers of Great Britain, assuming in all cases a feed water temperature corresponding to that of saturated steam at the pressure in the exhaust pipe. The British thermal units and the efficiency ratios on the basis of electrical horse-power are also given. In the latter case a perfect engine and dynamo, having a combined efficiency of unity, is assumed.

The water condensed in the receiver coils is included in the rates of steam consumption for reciprocating engines. In order to measure this water accurately during the tests its heat was necessarily wasted. In computing the British thermal units and the efficiency ratios this water was assumed to be returned to the boiler at a temperature of saturated steam 5 pounds below the throttle pressure, as this actually takes place in regular working conditions. The heat saved in this way amounts to between 1½ per cent. and 2½ per cent. of the total.

The consumption of British thermal units per horse-power per minute is more closely related to the coal pile than the pounds of steam, and the efficiency ratios afford by far the best means of comparing the economy of different engines. They take into account the more or less favorable conditions of steam pressure, superheat and vacuum under which the engines operate. Any increase of economy which is secured by increasing this ratio is so much clear gain. On the other hand, if a lower steam consumption is obtained entirely by raising the temperature of the steam supplied and lowering that of the exhaust, it is always partially (and may be more than entirely) offset by both an increase in first cost and an increased cost of maintenance for boilers, condensers, piping, etc. The efficiency ratio given in Fig. 2 for the reciprocating engine at full load exceeds

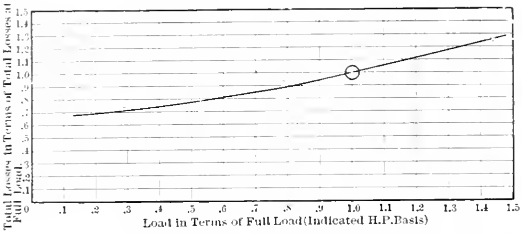

FIG. 2.—RELATION OF LOSSES AT DIFFERENT LOADS AND FULL LOADS.

that of the turbine by 15 per cent., while at half load it is 33 per cent. higher.

The combined efficiencies of these engines and generators were remarkably uniform for all cases, varying from the average less than 1 per cent. at either half or full load. A curve showing the relation of the total losses at various loads to the total losses at full loads plotted from reliable observations from a number of engines similar to these is shown in Fig. 2. While the total losses are fairly constant as predicted in the article of Mr. Mattice, there is an appreciable falling off for lighter loads. When the tests represented by curve *C*, Fig. 1, were made it was not considered worth while to make any determinations for less than half load. The form of the economy curve for these engines, however, has been determined by other tests for from quarter load to 50 per cent. overload, both with and without superheat.

A 1,500-kw McIntosh & Seymour engine recently tested by Prof. Ira N. Hollis, of Harvard University, under the direct supervision of Prof. L. S. Marks, is similar to these engines in every way, except that the stroke is shorter. The test conditions also were nearly identical except that the superheated steam was from 55° F. to 70° F. and the steam pressure somewhat lower. The efficiency ratios obtained in this series of tests on the basis of indicated horsepower for full, half and quarter load were .742, .733 and .668, and the B.T.U. 227, 227 and 242, respectively. For the curve *C* in Fig. 1, the corresponding ratios are .742, .768 and .690 and the B.T.U. 210, 208 and 232, showing a very fair agreement. In general, the results of tests of similar engines at different loads on the basis of indicated horse-power show the curve for overload to be nearly a straight line with a gradually increasing rate of steam consumption. For engines tested without receiver coils in use, and without superheat, an economy constant within two per cent. is indicated for from about .6 load to 1.3 load. The corresponding limits for the same engines with receiver coils in use are from .5 load to 1.2 load, and with superheated steam from 75 to 100° from .4 load to full load; the point of best economy becomes earlier as the rate of steam consumption decreases.

RESULTS OF TESTS AT FULL LOAD AND HALF LOAD.

An Electrified English Steam Railroad.

Aside from several lines on the Continent, England is the first country to apply electricity to heavy railroading; and this not through the electrical equipment of a new line, but by displacing steam on

FIG. 1.—VIEW SHOWING THIRD AND FOURTH RAILS.

an old road. The Lancashire & Yorkshire Railway, to which we refer, was described as to its location and electrical equipment in our issue of January 30, and we give below the details of the track construction.

The track is furnished with two third rails, one for distributing and one for returning the electric current to the power stations. The former is carried alongside each track in the usual way, while the other rail is placed between the running rails, uninsulated on the ties, this forming the principal part of the return circuit. While the joints of both the third and the fourth rail are bonded in the ordinary way, in the manner described below, the fourth rail is, also, cross-bonded to the running rails at their ends. While, by this arrangement, the troublesome bonding of the running rails is avoided, as are also the complications involved in using an insulated fourth rail for the return, the further advantage is obtained that the iron in the running rails are utilized as part of the return current. No collector shoe is provided on the train for the fourth rail, the current being delivered through the wheels to the running rails, and thence through the cross-bonds to the fourth rail. The insulation of this rail also makes it a comparatively simple matter to renew the running rails, without unduly interfering with the continuity of the return circuit.

The third and fourth rails are both of equal section, and consist of mild steel of special high conductivity, the resistance being proved by test to be not greater than seven and one-quarter times that of pure copper. As a matter of fact, the average resistance is somewhat lower. The rails weigh 70 pounds per yard, and are in lengths of 60 ft.

The third rail is supported at intervals of about 10 ft. on insulators of reconstructed granite, held in position by two clips, the center of the rail being exactly 3 ft. 11½ in. from the center line of the track, and the top of the rail 3 in. above the surface of the track rails. This dimension may be regarded as the British standard, having been agreed upon by all the main line steam railroad companies, at a meeting held at the Railroad Clearing House, on March 3, 1904, in order to obtain uniformity in case of extensions of third-rail system. It is of ample section to convey the full amount of current required by the trains, when between two substations, without causing any appreciable loss in voltage. Generally the third rail is placed in the 6-ft. way between the tracks, but occasionally it is brought outside the track to suit special conditions, and at all grade crossings the gaps are bonded with cable underground. Timber guards have been provided at all the busy places on the line, to prevent the possibility of any person coming into contact with the third rail. The fourth rail is supported on wooden blocks, and is placed in the middle of the 4-ft. way, between the two running rails.

FIG. 2.—A CROSSING AT SAND HILLS

FIG. 3.—JUNCTION AT SAND HILLS.

At most stations the third rail is interrupted and the ends are connected by cables to section switches. This apparatus consists of four knife switches, one for each end of the up and down line, which, in the ordinary way of working, are connected in parallel. By cutting out one of these switches in two adjacent boxes any part of the up or down line may be made currentless.

In providing for expansion and contraction, due to change of temperatures in the rails, they are divided into sections of 300 ft., and the joints between the rails making up this section are known as "fixed joints." The joints connecting the sections themselves are known as "expansion joints." At the fixed joints no provision is made for expansion or contraction, this being concentrated at the expansion joints. The fish-plates at the fixed joints are made as rigid as possible, and the bonds are four in number, two bonds being fixed in the web of the rail and two bonds in the flange of the rail.

It was deemed advisable to use bonds of semi-flexible type, which have a conductor built up of parallel strands of copper ribbon or "flat wire" with solid copper terminals. They are thus sufficiently flexible to provide for any movement which may take place at the joints, and are more easily adjusted in case of any variation in distance between the bond holes at the time of construction. The bonds at the expansion joints are four in number, of the same cross-section as those at the fixed joints, but all four are fixed in the flange of the rail. These bonds are also made of "flat wire."

The fish-plates at the expansion joints are of special design and properly slotted to provide for any change of length which may take place in the 300-ft. section. This system of bonding is carried out on both the third and fourth rails. The terminals of all the bonds are of solid copper, and are expanded in the bond holes by

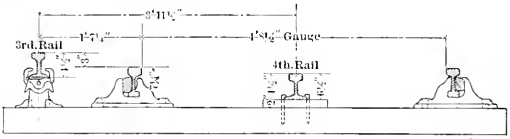

FIG. 4.—CROSS SECTIONAL VIEW OF TRACK AND CONDUCTOR RAILS.

means of screw or hydraulic compressors. Each track rail is bonded to the fourth or negative rail by means of flexible cable bonds. The bonds were supplied by the Forest City Electric Company.

Of the accompanying illustrations, Fig. 1 shows a section of ordinary track, Fig. 2 a section at a crossing and Fig. 3 the track at a junction. The traction rails and third and fourth (conducting) rails are shown in the cross-sectional view, Fig. 4.

Wireless Telegraph Newspaper at Sea.

A project is being worked out to publish a "multiple" daily newspaper on the Atlantic steamships each summer. The Marconigram says: "The newspaper will be of standard size, and will contain full telegraphic reports from the Associated Press. Its advertisements will be contracted for ashore, and it is expected that a very profitable business will thus be established. The combined circulation of this journal on board all steamships will be large enough to warrant its use by advertisers, whereas the issuance of different papers on board each separate vessel renders none of them a profitable medium, by reason of the comparatively small circulation of each. The projector of this publication is said to have contracted with the Marconi Company to receive as many words per day as the company can transmit with its facilities, at a rate per word which will prove extremely profitable to the company. The same matter will be printed in each edition of the paper, whether issued on board the *Lucania*, the *Kaiser Wilhelm* or the *Minnehaha*. The editorial rooms will be located ashore, either in America or Europe, and the news, editorials and miscellaneous matter for each edition will be furnished fresh each day by wireless, as well as the changes for advertisements. This is rather a revolutionary undertaking, but by no means chimerical. There are at times a population of 20,000 to 30,000 people afloat in ocean steamers between the United States and Europe. To furnish this vast multitude with a summary of the day's happenings, in various languages, is an enterprise which cannot fail to become popular."

Annual Report of the Bell Telephone System.

President F. P. Fish has made the following annual report to the stockholders of the American Telephone & Telegraph Company:

The results of the business for the year 1903, as shown by the treasurer's statement appended, were as follows:

Gross Revenue	$16,545,632.39
Expenses, including interest and taxes	5,980,967.30
Net revenue	10,564,665.09
Dividends paid	8,619,150.75
Carried to Reserve	728,139.97
Carried to Surplus	1,217,374.37

The following were the corresponding figures for the year 1902:

Gross Revenue	$13,277,457.33
Expenses, including interest and taxes	5,442,185.14
Net revenue	7,835,272.19
Dividends paid	6,584,403.75
Carried to Reserve	522,246.71
Carried to Surplus	728,621.73

The net output of telephones during the year 1903 was 629,197, making the total number in the hands of licensees 3,779,517. The number of exchange stations at the end of the year was 1,525,167, an increase of 247,184. The total mileage of wire for exchange and toll service was 3,958,891 miles, of which 677,229 miles were added during the year. Including the traffic over the long-distance lines, the daily average of toll connections was about 258,000, and of exchange connections about 9,876,000, as against corresponding figures in 1902 of 239,700 and 9,323,000; the total daily average for 1903 of connections both toll and exchange reaching 10,134,000, or at the rate of about 3,263,000,000 per year.

The total amount added to construction and real estate by all the companies constituting our system in the United States, during the year 1903, was:

For Exchanges	$24,060,900
For Toll Lines	8,866,000
For Land and Buildings	2,441,800
	$35,368,700

The amount added in 1900 was $31,619,100; in 1901, $31,005,400; and in 1902, $37,336,500.

The expenditure by this company in 1903 for the construction, equipment and supplies required for its long-distance lines was $4,365,614, making the total investment in long-distance lines and equipment up to the close of the year $26,861,805.

The development and course of the business of the company during the year have been satisfactory and the returns, as indicated by the foregoing figures, clearly such as to meet all reasonable expectations. In view of the general business conditions of the country, the increase in the number of subscribers and in the amount of telephone business done, shows that the efforts of your company and of the companies associated with it to give a service of substantial value, are appreciated by the public. The increase in gross and net revenue and in the amount carried to reserve and to surplus after the payment of interest and dividends, is a satisfactory indication that the investment that has been and should be made from year to year to build up a comprehensive telephone system that is adequate to the needs of the community will receive a proper return.

In former reports to the stockholders the necessity for developing and extending the facilities of your company to meet the demands of the public throughout the United States has been recognized and asserted. The history of each year emphasizes the soundness of this policy. Not only have the specific returns from such extensions proved to be adequate, but the strength and earning capacity of the company in all parts of the country are definitely increased by such development. No new toll lines are built, exchanges established, or telephones installed, without bringing in additional revenue from the construction already existing, as well as from the new construction. The conditions of modern business require communication over such large areas, and with so many people, that the public immediately responds when it has the opportunity of telephonic communication with new territory or with new subscribers; for the value of the service to users generally, largely increases with the extent of territory covered and the number with whom connections may be made. Your company and its associated companies are in a position to supply the comprehensive service required, and a proper return for the investment will surely reward their efforts to meet the demand that is made upon them. The extent of development required will vary from time to time with general business conditions. But even when those conditions are least favorable, extension of telephone facilities will still be called for, inasmuch as each year a larger proportion of the community recognizes the importance of the telephone in social and business life, as is shown by the constantly increasing number of Bell telephones in proportion to population.

Equally important is the matter of good service. Our companies are thoroughly impressed with the necessity of maintaining the Bell service at the highest practicable standard, and every effort is made to produce this result. The constant and intelligent study of operating methods that has been going on from the beginning and the many successive improvements in apparatus, have resulted in a definite control of this problem, the effect of which is everywhere shown in improved service. The complicated equipment required to make it possible to establish intercommunication between any two of hundreds of thousands of telephone users has now been standardized to a large extent. Standard methods of operating have been devised and put into practice. The result is not only an increased efficiency and better service, but also marked economy in maintenance and operation. Improvements in cables and devices to be used in connection therewith, and greater engineering knowledge, have made it possible to develop underground construction to a constantly increasing extent, and the field for underground work is now believed to be capable of an ultimate extension beyond anything that seemed possible to the engineers of a few years ago. This results in economy of operation and also, by reducing to a minimum the danger of accident to the outside construction, in an improvement in the service. It is safe to say that there is an element of permanency in the apparatus and equipment of to-day which did not characterize that in use a few years ago. The time will never come when further improvements may not be expected, both in methods of operating and in apparatus. There is no doubt, however, that the telephone service has now been so far standardized in these respects as to be on a par with many industries that are much older and which have had the intelligent and careful study of experts for a far greater period of time.

The work of perfecting the Bell service is not complete; but in view of the zeal and intelligence with which it is being pushed throughout the country, there is every reason to expect that the high standard now definitely established, and already attained in many places, will characterize the service generally.

In the report to the stockholders for the year 1902, reference was made to the significant fact that many of the competing telephone companies were beginning to realize that the rates adopted by them were too low and were seeking to raise those rates. This movement has continued with added force during the year 1903. The competing companies, in almost every city of any size in the country in which they have established exchanges, have found, sometimes as the result of a bitter experience, that the cost of doing the business was far greater than they anticipated. This has resulted in an increasing number of efforts on their part to raise their rates to a point nearer the Bell standard.

In particular they have learned that charges for maintenance and depreciation, which were lost sight of during the promotion stage of their business, were necessary expenses which must be taken care of before there was any question of earnings applicable to interest on bonds or dividends on stock.

The lesson has not even now been thoroughly learned, and not unfrequently the prospectuses of competing companies practically ignore those expenses. It is common for them to present figures showing that the entire cost of carrying on the business is from forty-five to sixty per cent. of the gross receipts that may be expected. The history of the business shows conclusively that an attempt to operate a telephone plant on any such basis is doomed to failure.

This matter of maintenance and depreciation is constantly before the eyes of our companies. The system of accounts, which is practically uniform for all the Bell organizations, forces them fairly to face this expense from month to month and from year to year. Before there is any question of profits, each company recognizes the necessity of reserving from its earnings such amounts as experience has shown to be adequate to keep its property in repair and replace it when worn out or destroyed. The sum properly to be charged varies to some extent in different parts of the country, on account of climatic conditions and the character of the plant employed, but the average allowance for maintenance of the Bell companies for the year 1903 was over thirty per cent. of their gross revenue.

As was stated in the report to the stockholders for the year 1902, the competition to which our companies are subjected is embarrassing chiefly to the extent to which it leads the public to believe that service can be given at rates that are too low to permit good service and a reasonable profit. The situation is now more favorable than ever before in this regard, and will continue to improve as the competing companies and the public become more correctly informed as to the conditions of the business. On the whole, it seems every year less probable that competition will have any substantial effect upon the prosperity of the Bell companies.

THE FIGURES IN LOWER LINE SHOW INCREASE FROM YEAR TO YEAR.

Dec. 20, 1899.	Dec. 20, 1900.	Dec. 20, 1901.	Dec. 20, 1902.	Dec. 31, 1903.

WM. DRIVER, *Treasurer.*

*Of this amount, $2,859,050.25 is for the dividends payable Jan. 15, 1904, to stockholders of record Dec. 31, 1903.

The developments of the past year also show that the feeling that it is better for the community that there should be one comprehensive system of telephonic communication instead of several, which was referred to in former reports, is clearly growing in all parts of the country.

It is an interesting and significant fact that many telephone companies which have started exchanges and to some extent toll lines in various parts of the country, independently of the Bell companies, but in territory which the Bell companies did not occupy, have by contract with our operating companies taken the Bell telephones and become connected with our system on terms favorable to both parties. There are now over 120,000 of such sub-licensee stations connected with the lines and exchanges of the Bell companies, and the movement in that direction is gaining.

Generally speaking, the business of your company and of the companies associated with it is on a sound basis and, with good management and a proper development to meet the demand, the continued prosperity of the Bell organization seems secured.

The suit of the Western Union Telegraph Company against this company, which has been pending since the year 1884, and which was decided in favor of this company by Judge Lowell, sitting as master, and by Judge Colt in the Circuit Court of the United States, has been decided adversely to this company by the United States Court of Appeals for the First Circuit.

The decision is to the effect that, under a technical reading of the contract made by the predecessor of this company with the Western Union Telegraph Company and its associated companies in the year 1879, this company may have to account to the Western Union Company for a certain percentage of some of the stocks and bonds which it received from its licensee companies prior to 1896, when the contract expired.

WM. R. DRIVER, *Treasurer.*

That the validity of this decision is doubtful is shown by the fact that Judge Lowell and Judge Colt took a contrary view, and at the proper time every effort will be made to secure a revision of the decision of the Court of Appeals. Meanwhile the matter has been referred to a master, who will report as to the amount, if any, which this company should pay the Western Union Company under the decision of the Court of Appeals, and his report, when made, will be subject to revision by the courts. Even if there should be any ultimate recovery against us—which, as we are advised by counsel, is by no means certain—it is not believed that the amount recovered will be relatively large. It certainly will not be large enough to impose any appreciable burden upon the company. Certain classes of the stocks in question are expressly excluded from the accounting by the opinion of the Court of Appeals, and there are many considerations which, in the opinion of our counsel, will reduce substantially the amount, if any, that may be recovered in the case of the remaining stocks.

Your directors desire to express their appreciation of the zeal and intelligence with which the employees of this company and the officers and employees of the operating companies are co-operating to bring about the best results in our business. There is an excellent spirit throughout the organization and everywhere a harmony of effort and aspiration which is most satisfactory.

The report is accompanied by the foregoing important statistics as to instruments in the hands of Bell lincensees, under rental and by the financial statements given.

The Telephone Substation.—II.

By ARTHUR V. ABBOTT, C.E.

SOME experiments upon induction coils have recently been made in the Electrical Engineering Laboratory of the Iowa State College. A set of 23 coils was obtained, four of which were those commonly made by well-known telephone manufacturers, while the remaining nineteen were experimental coils constructed for the purpose of trial. These coils were tested by selecting one (No. 21 of Table No. 4) as a standard and comparing all of the other coils

gives the results of the tests with the 6-mile line, and the other those obtained from the 106-mile circuit. The opinions of the investigators making these experiments is expressed in the columns headed volume and clearness. The figures therein contained show the idea which was formed as to relative intensity and clearness of articulation of each coil as compared with No. 21.

Unfortunately the results shown in Tables 4 and 5 do not lead to the formulation of any rules as to the best proportions to be observed in the design of induction coils. On the contrary, these experiments seem to teach that coils of quite widely varying properties yield fairly satisfactory results. Theory indicates that to secure the very highest efficiency the coil should be proportioned to the particular transmitter, receiver and line with which it is to be connected. In commercial operation this is impossible, so it is perhaps fortunate that practice shows it to be feasible to work over widely differing lines, with coils of many designs and obtain sensibly the

 4 to hook including receiver.

same results. Probably, therefore, the best guide to the plan of an induction coil is to be found by dissecting a number of coils, that have survived the test of time and experience, and building along the lines thus indicated. As an aid to the designer the proportions used by half a dozen or more of the principal manufacturers, will be found in Table V, while the succeeding drawings and accompanying specifications, still further exemplify the building of induction coils.

Considering the importance of the induction coil, too much pains cannot be taken in its design, or too great liberality allowed in its proportions. In its construction and assemblage, the very best material and the highest standard of workmanship should be used. Under increasing competition there is a great and mistaken tendency to skimp both in quality and quantity. The general aim of design should be to produce a coil of the least possible impedance and the greatest mutual inductance. To this end the primary should be of large wire, the core ample in size and long enough to accommodate the necessary turns of the primary, which should not be less than 300 in two layers. The ratio of transformation between the primary and secondary should be from 8 to 10, and the size wire employed in the secondary such as to enable the requisite number of turns to be obtained in not to exceed five layers. For both primary and secondary white single silk-covered copper wire should be used, and it is desirable that each coil should be wound with a single piece without splices. In the winding care should be taken to wind evenly and uniformly without piling or crossing any of the turns. Between the primary and the secondary an insulation of at least four thicknesses of paraffined paper should be provided, and it is well to interpose two thicknesses of paper insulation in the middle of the secondary. The terminals of both primary and secondary should be reinforced by means of stranded wire extended from the inside of the winding through holes drilled in the heads and soldered to clips secured either upon the head or upon the base. The stranded terminal wire should be heavily insulated with a silk or cotton wick. The core should be composed of the very best and softest Swedish iron wire, thoroughly annealed. The wire should not be over a No. 20 B. & S. gauge and preferably No. 26 or 28. It should be thoroughly varnished, cut to proper length and packed into the core tube, and each piece of wire composing the core should be the full length of the tube. Short pieces or spliced pieces should not be allowed.

For the coil frame fibre heads about ¼ in. in thickness and from 1 in. to 1¼ in. square, mounted upon a fibre tube ½ in. in diameter and from 4 to 6 ins. in length is preferable. While many makers use paper tubes and wooden heads, fibre is much more desirable.

Production of Artificial Gas.

A report just issued from Washington, by Mr. Edward W. Parker, gives the following figures of gas production that are of interest. The table shows the total quantity of gas made from coal by the 533 companies distributed over 44 States and Territories. Prices for artificial gas are low in States where natural gas is used largely in the principal cities, as in Illinois, Indiana, Kentucky, Ohio, Pennsylvania, West Virginia and also Massachusetts, where a large portion of the gas made is a by-product from coke-making in retort ovens:

TABLE I. PRODUCTION OF GAS AT GAS-WORKS AND COKE-OVEN PLANTS IN 1902.

Number of plants reporting	533
Coal carbonized, short tons	5,015,511
Gas made, cubic feet	30,764,625,332
Gas sold, illuminating purposes:	
Cubic feet	23,401,318,526
Value	$23,688,963
Average price per 1,000 cubic feet	$1.012
Gas sold, fuel purposes:	
Cubic feet	5,677,755,029
Value	$5,653,918
Average price per 1,000 cubic feet	$0.996
Gas sold, total:	
Cubic feet	29,079,073,555
Value	$29,342,881
Average price per 1,000 cubic feet	$1.009
Gas unaccounted for, cubic feet	1,685,551,777

TABLE II. PRODUCTION OF GAS AT GAS-WORKS IN 1898.

Number of companies reporting	433
Coal carbonized, short tons	2,042,698
Gas made, cubic feet	19,469,464,957
Gas made per ton of coal, cubic feet	9,465
Gas sold, illuminating purposes:	
Cubic feet	15,955,149,507
Value	$18,953,114
Average price per 1,000 cubic feet	$1.188
Gas sold, fuel purposes:	
Cubic feet	2,476,051,907
Value	$2,549,181
Average price per 1,000 cubic feet	$1.0295
Gas sold, total:	
Cubic feet	18,431,201,414
Value	$21,502,295
Average price per 1,000 cubic feet	$1.1666
Gas unaccounted for	1,038,263,543

Of the total amount of gas produced in the United States in 1902, 1,685,551,777 cubic feet, or 5.48 per cent., were lost by leakage or accident. The marketed product amounted to 29,079,073,555 cubic feet, of which 23,401,318,526 cubic feet, or 80.45 per cent., were sold for illuminating purposes and 5,677,755,029, or 19.55 per cent., for fuel. As a usual thing the gas sold for illuminating purposes brought higher prices than the fuel gas, but there were a few instances where fuel gas was sold at high enough figures to make the average price for this gas in the State higher than illuminating gas. The price of illuminating gas varied from 65.2 cents per 1,000 cubic feet in Massachusetts to $2.13 in Montana, Nevada and New Mexico. Fuel gas ranged from 29.2 cents in West Virginia to $1.98 in Oregon. The average prices of fuel and illuminating gas in 1902 for the country as a whole show a difference of only 1.6 cents per 1,000 cubic feet, the former being 99.6 cents and the latter $1.012.

An Electrical Engineer in Thibet.

Mr. Oscar T. Crosby, the well-known electrical engineer, who, during the past few years has devoted a great deal of his time to exploration in the remote regions of the world, including Abyssinia, Somaliland, the Blue Nile, etc., has just returned to this country after a most interesting expedition through Turkestan and Thibet. While in England on his way home he addressed the Royal Geographical Society on the subject, and a number of his friends in this country having invited him to redeliver this lecture, he appeared last week at the American Institute before a gathering of some 400 or 500 people under the auspices of the New York Electrical Society and of fellow-members in the American Institute of Electrical Engineers. The lecture made a most agreeable diversion from the usual programme of the Society and was a delightful and fascinating narrative of adventure and peril in the mysterious region beyond the snowy ranges of the Himalayas, and in a land upon which Russian and British political intrigue is now said to be focussed, the Indian government having recently sent an expedition to Lhassa. For over two hours Mr. Crosby, who has keen powers of observation, a splendid command of language, and a fine sense of humor, held his audience entranced while he detailed the successive stages of his long journey, during the last 50 days of which, spent about 15,000 ft. above sea level, he did not take his clothes off; and during the last five days of which his party was on the very verge of starvation. Although he did not succeed in reaching the capital of the Grand Llama, Mr. Crosby was able to see a great deal of the life and scenery of Turkestan and Thibet and secured a number of interesting photographs, many of which were shown on the screen by lantern. He also brought back with him ancient manuscripts from some of the sand-buried cities of central Asia, whose history still remains in such impenetrable gloom. Before starting on his trip, Mr. Crosby provided himself with a phonograph, upon the cylinder of which his credentials and attributes were set forth in the choicest Chinese dialect of the region visited; but this vocal passport he had to leave behind him with a great deal of other baggage which succumbed to the rigors of the expedition. At the close of the lecture, on motion of Vice-President Mullin and Mr. Frank J. Sprague, an enthusiastic vote of thanks was passed to the lecturer for the great pleasure he had afforded the Society and so many of his old friends. During the evening it was announced that immediately upon the Union Engineering Building becoming an accomplished fact, President Carty had filed with the conference committee, on behalf of the Society, a request that it might be given accommodation and facilities within the building: and that this request had been favorably acted upon. This news was received with great enthusiasm.

Recent Electrochemical Developments.

MANUFACTURE OF SULPHURIC ACID FROM SULPHURETED HYDROGEN GAS.

The Salom process for the reduction of lead from galena consists in the use of a cathode of galena (lead sulphide) in sulphuric acid as electrolyte. The cathodic reaction is the reduction of lead sulphide to metallic lead with a simultaneous evolution of hydrogen sulphide gas. While the main object of the process is the production of lead, yet the hydrogen sulphide is a valuable by-product and something must be done with it. In a patent granted to Mr. P. G. Salom on March 22 a method is described for using it for the manufacture of sulphuric acid.

The hydrogen sulphide gas is first burned, to form sulphur dioxide. The sulphurous-acid gas is then oxidized in the presence of water by means of electrolytic action, the current of gas being subjected to progressive anodic treatment in a series of divided receptacles through which it travels. The process is so conducted as to permit the progressive transfer from time to time of the contents of each receptacle into the next one of the series, and the discharge of the contents of the ultimate receptacle (in which the action has proceeded to the fullest extent) into a receiving tank, the gravel of the liquid contents being in the inverse direction to the flow of the gas through the same. The apparatus used by Mr. Salom is very similar to that employed by him formerly for lead reduction and consists of a stack of trays placed one upon the other.

EXTRACTION OF COPPER FROM COMMINUTED MINERAL MIXTURES.

In a patent, granted on March 22, Mr. E. A. Le Sueur, who is best known by his early pioneer work in the development of the diaphragm cell for the electrolysis of sodium chloride, describes a process for obtaining the copper from mineral mixtures containing only a very small amount of copper, as, for instance, the waste sands from stamp mills. Mr. Le Sueur proposes to treat them by a wet process and his process consists, therefore, of two steps: The first using the solution of the copper, the second its precipitation.

For solution he uses an ammoniacal solution of cupric hydroxide, with the addition of certain apparently inert salts, like ammonium sulphate. If there is no access of air, the reaction is a reduction of the cupric ions, already in the solution, to the cuprous state, while the metallic copper passes simultaneously into solution, also in the cuprous state. While in the sense of the ionic theory this is an electrochemical phenomenon, this step is purely chemical from the practical point of view, since no current is passed from the outside through the solution.

For the second step—the precipitation of the copper from the solution—either chemical or electrochemical means may be employed. In the latter case the author suggests the following cycle, the whole process being conducted in the form of a cycle, as follows: Copper is first dissolved, as described before, in cuprous form, about the same weight of copper going into solution as is contained in it in the cupric state at the start of the operation. Then electrolysis begins with an insoluble anode and as much copper is now deposited upon the cathode as had gone before into solution, while the other part is oxidized from the cuprous to the cupric form at the anode. Then the solution is again in its original condition and may again be used for leaching out other ore.

STORAGE BATTERY INVENTION.

A patent, granted to Mr. S. Lake, of Bridgeport, Conn., relates to mechanical details of the connection of the battery plates of common size to the bus-bar in such a way that individual plates may be easily removed. In a patent, granted to Mr. M. C. Burt, of Chicago, a cooling device is described which is intended to counteract the heating of the solution by Joulean heat.

Mr. C. B. Askew, of Chicago, refers, in a recent patent, to details of construction of a grid for pasted storage battery plates. The grid is made of sheet lead transversely sawed from opposite sides in planes at right angles to the medium plane of the sheet, so that each side of the sheet is provided with parallel grooves. The grid is also provided with perforations.

CURRENT NEWS AND NOTES.

TURBINES FOR CUNARDERS.—Great interest has been aroused in marine engineering and electrical circles by the announcement that the Cunard Steamship Company has decided to adopt steam turbines in the new fast steamers which are to be built under an agreement with the British Government, which will have a gross tonnage of 28,000, which are expected to travel at a speed of 25 knots an hour and will cross the Atlantic in about five days.

WIRELESS AT THE ISTHMUS.—A cable dispatch from Panama of March 26 says: "The postmaster at Panama to-day received official cable advices from Minor Keith, who is in Costa Rica, stating that a system of wireless telegraphy was successfully inaugurated last Thursday between Port Limon, Costa Rica, and Bocas del Toro, Panama. The convention recently held here authorized the President of the Republic of Panama to sign a contract for the installation of this system. Mr. Keith will also establish a wireless station at Colon."

UNDERGROUND CONSTRUCTION.—President Edgar, of the National Electric Light Association, has asked Dr. S. S. Wheeler to act as chairman of the committee to examine the papers of those competing for the gold medal offered by Past President Doherty for the best paper on underground construction, to be presented at the twenty-seventh convention of the association. Dr. Wheeler has consented to serve, and the other members of the committee will be Mr. Louis A. Ferguson and Mr. H. G. Stott. All of these gentlemen are excellent authorities on the subject, and it is hoped that the papers—which are to be handed in before April 21—will be of a character to make their work a most interesting one. Dr. Wheeler, it may be noted, was at one time electrical engineer for the New York Board of Electrical Control, in the early days of its subway work for underground wires.

MUNICIPAL ELECTRICIANS.—There will be a meeting of the executive committee of the International Association of Municipal Electricians on Saturday, April 2, at 10 A. M. at the Astor House, New York City.

POSTPONEMENT OF IOWA ELECTRICAL CONVENTION.—The Iowa Electrical Association convention which was to have been held at Des Moines April 13 and 14 has been postponed one week to April 20 and 21. Headquarters will be at the Hotel Savery.

WIRELESS IN CHINA.—It is stated that the Italian legation at Pekin has been provided with a Marconi wireless telegraphy station which enables direct communication to be maintained with the vessels of the Italian fleet in Chinese waters. Thus the Italian legation will be able to communicate with its ships at Taku and Tien-tsin without recourse to the lines of the Chinese Government.

WESTINGHOUSE RUSSIAN GIFT.—The text of the acknowledgment by the Empress of the gift of $5,000 by the Russian Westinghouse Company to her fund for the relief of the sick and wounded is as follows. It is signed by Count Rostovtsoff: "It has been a pleasure to her Majesty, the Empress Alexandra Feodorovna, to express her sincere thanks to the stockholders of the Westinghouse Company, consisting chiefly of citizens of the United States, who have placed $5,000 at her Imperial Majesty's disposal for the purpose of aiding the sick and wounded soldiers in the Far East, as well as for their expression of sympathy with Russia, which at the present time will have peculiar value. It is my pleasant duty to inform you of this by her Majesty's order."

THE YORK HAVEN POWER PLANT.—The officers and promoters of the York Haven Power Company are determined not to allow the damage which the recent freshet wrought to the extensive plant at York Haven to interfere with their original plan which was to have the plant in operation and supplying current to York and other towns by next May. At a meeting just held by the officers and the largest stockholders the reports of the damage were received. Plans were at once developed for the immediate repair of the plant. A temporary power house of wood is to be built over the machinery and a permanent brick structure will be reared over this. Repairs to the machinery can be made quickly and by the use of a temporary switchboard and the quick clearing away of the debris in the big race it will be possible to have the plant in operation within the next sixty days. The experts estimate that $10,000 will cover the cost of repair.

NEW YORK POOL ROOMS.—The Western Union Telegraph Company has been co-operating vigorously with the city authorities to stop business in the gambling pool rooms. It is said that Mayor McClellan's attention was directed to the controversy between the Western Union Telegraph Company and the several hundred pool rooms in this city—all of which the police declare are closed—the telegraph company having declared its ability, by withholding its service from the pool rooms, to put them all out of business, if certain leaks were not stopped. The Mayor was asked if it had occurred to his administration that by bringing pressure to bear on the telegraph company and compelling it to stop serving pool rooms it might do what the police admit they have great trouble in doing. "Do you mean," replied the Mayor, "that we should indict the officials of the Western Union Telegraph Company as accessories to the fact?" A moment later the Mayor, still thinking it over, said: "If the telegraph company carries out its threat to close the pool rooms, I guess the pool rooms will have to go to see brother Marconi."

TEXAS ELECTRICAL ASSOCIATIONS.—The Southwestern Gas, Electric and Street Railway Association and the Southwestern Electrical Association will hold a joint convention at Dallas, Texas, on April 25, 26 and 27. This will be the fifth annual convention of the former association, and the second convention of the latter. It is proposed to consolidate the two associations and the proposition will be voted upon at that time. Among the subjects to be discussed at the meetings will be: "Advantages of the Combination of Gas and Electric Light Plants"; "The Operation of Single-Phase Motors from the Central Station Standpoint"; "Framing of City Franchises for Public Service Corporations"; "Combination of Public Utilities in Small Cities"; "Economics of the Meter"; "Benefits and Evils of Telephone Competition"; "Accidents on Street Railways and Damage Suits"; "Central Station Accounting"; "Electricity and Risks"; "Requirements of the National Board of Underwriters in the Southwest," and "Developments of Interurban Railways in the Southwest." Mr. F. E. Scovill is secretary of the Southwestern Gas, Electric and Street Railway Association with headquarters at Austin, Texas.

THE NAME OF EDISON.—An article in *Cassier's Magazine* for April states that when Mr. J. Ricalton returned, in 1889, from a year's exploration tour in foreign climes, made in Edison's behalf in search of a suitable bamboo for filaments, he told how he had learned to regard Edison as the most widely known man in the world at that time. In all his journeyings in the Far East he had been astonished many times to find his name so familiar; even the unlettered natives of half-civilized countries had learned to associate it with the electric light. His donkey boy in the streets of Cairo was endeavoring, in broken English, to tell him something about the Khedive, when Mr. Ricalton asked him the name of the American Khedive. The boy shook his head to indicate that he did not know. Mr. Ricalton mentioned the name Harrison, who at that time was President of the United States, but the boy did not recognize it. Then Mr. Ricalton mentioned Edison's name: the boy smiled cognizantly and drawled the name, "Ed-ee-sone," while pointing to an electric light in front of the hotel. A few weeks later Mr. Ricalton mentioned the name to his courier in Morocco, whereupon the latter quickly proceeded to offer his knowledge of the man. Edison's name truly, Mr. Ricalton concluded, was a household word even at the ends of the world.

TEST OF COMMERCIAL AUTOMOBILES.—At the present time eighteen entries have been received by the Automobile Club of America for the service test of commercial motor vehicles which is to be held under the auspices of the club next week. There are eight classes according to the weight-carrying capacity. In the first class, including vehicles carrying 1,000 pounds or under, there are three entries, all being light gasoline delivery wagons. The second class has the largest number, nine vehicles, their carrying capacity limit being between 1,000 and 2,000 pounds. Of these nine the electrics are most numerous, five of the nine wagons being equipped with electric motors. Four of them are delivery wagons and one an express wagon. Of the other four, three are gasoline delivery wagons and one a steam delivery wagon. The third class, between 2,000 and 3,000 pounds, has two cars entered, both gasoline delivery wagons. The fourth class, between 3,000 and 4,000 pounds, has one, a gasoline truck. The fifth class, between 4,000 and 5,000 pounds, has one, an electric truck. No entries were made for the sixth and seventh classes, but in the eighth class, for vehicles carrying from 8,000 to 10,000 pounds, two heavy trucks are entered, one being a gasoline-electric truck and the other a steam truck. With the exception of the last class all the vehicles will perform the regular daily service of two local express companies, while the two big trucks will do the regular work required of the wagons in use by a large brewery. The club has engaged the services of a number of observers to assist in checking results.

LETTER TO THE EDITORS.

Cheap Current From Municipal Plants.

To the Editors of Electrical World and Engineer:

SIRS:—In your issue of March 19 Mr. C. W. Koiner, superintendent and chief electrician of the Madison County Gas & Electric Company, of Oneida, N. Y., takes exception to a statement made in my descriptive article relating to the South Norwalk municipal plant, published in your issue of February 20, regarding the rate of 1.9 cents per hp-hour by meter as charged by this plant for a consumption of say 50 hp-hours for 26 10-hour working days per month. I said in the article that there is no place known with the exception as given where power can be obtained so cheaply.

Mr. Koiner says that this statement is "erroneous" and "misleading," and that he "knows of cities and towns in his neighborhood that sell current for less than 1.9 cents per hp-hour." Assuming that the gentleman is familiar with his subject, I am willing to acknowledge my ignorance in the presence of superior knowledge and humbly ask him to make good his assertion, by giving the names of the "cities and towns in his neighborhood" that make a business of selling electric power under the conditions and below the rate to which he takes exception. I believe that this information will be relished by the consumers of power in the places in mind, and further, that, as it is undoubtedly the aim of all good central station managers to give the greatest value possible, with due regard for profit, for the least cost of the consumer, such information would awaken a certain degree of professional curiosity as to the economies that make a lower rate possible.

The gentleman takes the opportunity, before concluding his remarks, with some seeming loss of dignity, to say disagreeable things about those who operate or advocate municipal central stations, from which it might be inferred that he is addicted to making extravagant assertions. I think that most of those who have to do with central stations (private or municipal) are a pretty good lot of people, and am glad to believe that I have many friends on both sides, among whom I would like to add the name of Mr. Koiner.

When visiting my old home not a great way from Oneida, it will be my pleasure to run in on Mr. Koiner, for a friendly call. I am thoroughly in accord with his sentiments regarding misstatements, only I would go a little further and say that "every misleading statement emanating from agitators" for or against "municipal ownership should be called to account." Both sides should be fair to each other and justice will follow. Private and municipal plants each have their place, and where one does right the other is not needed.

I see that my friend is faithful to his trust. I try to be the same to mine, and the question is not that I happen to be in charge of South Norwalk's municipal plant, but that I am here for results, without regard to who owns the plant, and incidentally I can look upon the good and bad of both private and municipal ownership with regret for the bad and joy for the good in each.

South Norwalk, Conn. A. E. Winchester.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

Dynamos, Motors and Transformers.

Speed of Direct-Current and Induction Motors.—Hobart.—An illustrated paper read before the (Brit.) Inst. Elec. Engs. on the rated speed of electric motors as affecting the type to be employed. High speed is a very favorable condition for the continuous-current motor, but up to certain limits conduces to improve results for induction motors. The author gives a great many details on the design and behavior of direct-current and induction motors for varying speeds, and gives two comparative tables with all the dimensions, efficiencies, weights and costs for 150-hp continuous-current motors running at speeds between 68 and 1,224 and for 150-hp induction motors, operated at 21 cycles per second at synchronous speeds of 70, 210 and 630, or at a frequency of 63 cycles at synchronous speeds of 630, 940, 1,260 r.p.m. The principal conclusions at which he arrives are: Induction motors are for all capacities, considerably cheaper than continuous-current motors of equivalent ratings. The general performance and the mechanical construction of induction motors improve rapidly with increasing rated speeds. The general performance and the mechanical construction of continuous-current motors improve rapidly with decreasing rated speeds. The use of very low-speed induction motors and very high-speed continuous-current motors ought to be avoided whenever this is commercially practicable.—Lond. *Elec.*, March 11.

References.

Magnetic Dispersion in Induction Motors.—Behn-Eschenburg.—A continuation of his paper. He shows that in the ordinary constructions of motors with open slots the part relatively contributed by the peripheral dispersion to the total values of the dispersion coefficient plays a very subordinate part. For closed slots, in which the iron bridge is made thin enough, this dispersion coefficient may be estimated about four times greater than for slots with slits. He then begins a general discussion of the winding coefficient. The paper is to be continued.—Lond. *Elec.*, March 11.

Alternators in Parallel.—Koehler.—An elementary article, illustrated by diagrams, in which the author discusses the fundamental principles of the operation of alternators in parallel, and describes the working of phase indicators.—*Elek. Anz.*, March 6.

Lights and Lighting.

Candle-Power and Temperature.—Eisler.—A paper in which the author refers to Lummer and Kurlbaum's determinations of the light given out by incandescent platinum at varying temperatures. They have developed an empirical formula which shows the rapid increase of candle-power with the increase of absolute temperature. This relation may also be found indirectly by means of calculation on the basis of Langley's figures for the sensibility of the eye in the different portions of the spectrum, and on the basis of the distribution of energy in the spectrum of an incandescent body. The author carries out this calculation and shows that the measurements of Langley and those of Lummer and Kurlbaum confirm each other, and that the following conclusions may be drawn with a certain degree of probability. The physiological action of combined light (that is, light of different wave lengths) equals the sum of the single actions of the light of the different wave lengths in it. The radiation of the theoretically "black" body differs from that of platinum in the visible part of the spectrum in absolute value, but both depend in exactly the same way upon the temperature. For both the black body and platinum there is the same relation in candle-power and temperature. The author criticises former attempts to give figures for the mechanical equivalent of light. Tumlirz, basing his conclusions on tests of the Hefner lamp, had stated that the visible radiation has the energy value of about 1,900,000 ergs per second. From this figure it follows that with no type of illumination would it be possible to get more than 5.2 cp per watt. The author shows that this conclusion is wrong since the physiological value of the visible radiation depends greatly on the temperature of the light. For about 4000° absolute temperature (arc light) this value is 3.5 times greater than for 1800° absolute temperature (Hefner candle). It would, therefore, follow that light corresponding to the composition of the spectrum of the black body at 4000° would give 18.7 candles per watt, if the efficiency was 100 per cent. If one desires to give a figure for the most ideal case of the generation of light, one might assume a process in which the energy is completely transformed into radiation of light of that wave length for which the human eye has the highest sensibility. For this special wave length one would get 65 candles per watt with an efficiency of 100 per cent. But such a light would not be practical, since a practical source of light should be of the same color composition as sunlight. For this case he gets a figure of 27 candles per watt for an efficiency of 100 per cent. In practice we will never attain this value, if some parts of the energy are transformed into invisible radiation and into other forms of energy which are not wanted. But even if by the use of phenomena of luminescence we should succeed in transforming the energy completely into visible radiation, there would be, nevertheless, a difference in the value of different sources of light according to the degree in which such "perfect" luminescent lights approach the spectrum of the sun.—*Elek. Zeit.*, March 10.

Photometric Tests of Street Lamps.—A table giving the results of comparative tests of street lamps extending over a period of 18 months. The tests were made by Bradley. The total cost per candle-power per year was found to be 21.5 cents and 17.46 cents for two sets of electric arcs with opalescent globes; 34.4 cents for electric arcs with muranese globes, 56.6 cents for refuge lanterns (4 mantels), 15.3 cents for Sugg's high-pressure gas lamps, 40 cents and 36.6 cents for two different sets of incandescent gas mantels, and 59.8 and 96.4 cents for two sets of triple flat-flame lamps. In the case of incandescent mantels, including high-pressure lamps, great variations in candle-power are found to be due to the condition of the mantels—what appears to the naked eye as a slight diminution in intensity, resulting in an enormous loss of candle-power. A slight defect in any of the incandescent mantels in high-pressure lamps causes a great loss of candle-power.—Lond. *Elec.*, March 11.

TRACTION.

Mersey Railway.—KIRKER.—A paper read before the Manchester Section of the (British) Inst. Elec. Engs. Electric traction was inaugurated on May 3, 1903, arrangements having been made for an instantaneous and complete transformation. The steam traffic ceased on May 2, and electric traction, with a complete train service, began on the succeeding morning. The three-minute schedule has been successfully maintained from the beginning. The trains vary in size from two to five cars. In the three, four and five-car trains there are two motor cars, situated at the extremities. Multiple-unit control is used. The average electric load is 22,000 kw-hours per day. Concerning ventilation (which is important since the road is a tunnel road) he says that under steam conditions the average cost per half year exceeded $12,000; with electric traction it falls below $1,000 for a corresponding period. As to the schedule speed, the rate was 15 miles per hour for the steam trains and electric traction was laid out on the basis of 20 miles per hour, which is attained. With the steam locomotives the train mileage was less than 6,000 per week. During the last quarter of 1903 the electric trains lacked but 40 miles on an average of 15,000 miles per week. Concerning the coal consumption, it was estimated that the average would not exceed 4 pounds per kw-hour at the switchboard, and the average for the last quarter of 1903 and the first six week of this year is below 4 pounds. The consumption of energy for a loaded three-car train was estimated not to exceed 9.25 kw-hours per train mile; for the last quarter of 1903 the actual figure was less than 9. The cost of operation per train mile (including the power house expenses, the cost of power for operating and lighting trains, the maintenance of electrical equipments, cars and collector rails) was below 13.5 cents per train mile for an average train 230 ft. long, and weighing 105 tons, including motors. The corresponding cost per steam train, 200 ft. long and weighing 77 tons, exclusive of locomotive, but working at a schedule speed of 15 miles per hour instead of 20, exceeded 22 cents per train mile. The total power station cost did not exceed 0.7 cents per kw-hour during the last quarter of 1903.—Lond. *Elec. Rev.*, March 11.

Capacity of Traction Motors.—MÜLLER.—An article in which the author describes a method for determining the size of a traction motor by calculation on the basis of tests of the heating of kindred motors. When used on the road, the motor assumes a certain end temperature which it maintains nearly constant throughout service. Under these conditions the heat which it gives out by radiation is equal to the heat produced by the electric current in the motor. This end temperature is required to be not over 75° C. over that of the surrounding air (in Germany). The total heat which is produced in the armature conductors is the sum of i^2t, where i is the current in the conductors at any time and t is a time element. The average iron loss is the sum of $Wt \div T$, where W represents the different iron losses during the different time elements, t and T, is the total time of a trip and return trip. If both the field and armature coils of a traction motor are tested at a series of voltages, for instance, 200, 300, 400, 500 volts, for continuous running at a temperature of 75° C. over the temperature of the surrounding air, then the watt represents that heat which the motor is able to give off at the iron losses which correspond to these voltages. One is, therefore, enabled to plot the capacity for continuous running as a function of the iron losses. A curve is thus obtained which, when once determined for the type of motor, is sufficient to determine the size of the motor for given conditions of service. Since a certain voltage corresponds to the determined average iron losses, one may say that the variations of load in the traction service may be represented by a continuous load, the current of which is given by the sum of $i^2t \div T$ and the voltage by the sum of $W t \div T$.—*Elek. Zeit.*, March 11.

Monorail.—A description of the model of Behr's monorail for the St. Louis Exposition. It is built on a scale of ¾ in. to the foot and comprises a circular track and a motor car running on it. Current is led to the car by means of two miniature rails running along each side of the track. This itself consists of a single running rail which is carried—in actual practice—a few feet above the ground, and of four guide rails which serve to steady the car in case it should tend to oscillate from any cause. The five track rails are carried by triangular supports of metal, the running rail being placed at the apex and the guide rails at the sides of the triangle. Owing to the mechanical difficulty of reducing the motors to scale, somewhat larger motors had to be installed and they are placed in the passenger compartment of the car. This in conjunction with the very sharp curves of the model track is said to account for the somewhat jerky and unsteady running.—Lond. *Elec.*, March 11.

REFERENCES.

Electric Railways in Italy.—A note stating that on the Milan-Varese Railroad several trains have recently been equipped with the multiple-unit system and the results have been satisfactory. The continuation of this road from Varese to Luino, which is now operated by steam, will also be equipped for electric traction and three-phase motors will be used in this case. The line from Castle Raimonda to Camerino in central Italy is now being equipped electrically with the direct-current system. The road from Turin to Torre Pellice, of about 50 km. length, is to be changed to electric traction, and it is intended to use a single-phase system.—*Elek. Zeit.*, March 10.

Tramway Traffic.—UPTON.—The first part of an article on through booking and conveyance of passengers, parcels and merchandise on tramways and light railways.—Lond. *Elec. Rev.*, March 11.

INSTALLATIONS, SYSTEMS AND APPLIANCES.

Hackney Station.—The first part of an illustrated description of the Electricity Works and Destructor Plant of the Metropolitan Borough of Hackney. The supply is on the direct-current system at 40 volts, and from the commencement flat rates of 8 cents for lighting and 4 cents for power have been charged for electrical energy. The plant began working in 1901 with a capacity of 1,800 kw, which has already been increased to 3,372 kw. The refuse destructor consists of 12 cells, each group of four cells being designed to deal with 60 tons of refuse per day. The generating plant consists of two 250-kw sets, two 300-kw sets and one 1,500-kw generator, all driven by vertical triple-expansion enclosed high-speed engines, provided with condensing plant. In addition there is a booster of 50 kw driven by a motor.—Lond. *Elec. Rev.*, March 11.

REFERENCE.

1,000-kw Double-Current Turbine Generator.—An abstract of a specification for a 1,000-kw, double-current generator for the Stepney Electricity Works. It consists of a steam turbine coupled to two 500-kw double-current generators in tandem on an extension of the turbine shaft. Each machine is shunt wound and multipolar and provided with a commutator and three slip rings, the frequency of the three-phase currents being 40 to 60 periods per second.—Lond. *Elec.*, March 11.

ELECTRO-PHYSICS AND MAGNETISM.

N-Rays.—In order to disprove the assertion that the effect of N-rays is purely subjective, Blondlot has made experiments in photographic registration of the effect of these rays upon a small electric spark. In all the 40 experiments made only one was unsuccessful, while all others showed a distinct effect of the N-rays. Ballet has used N-rays successfully in order to diagnose some diseases of the nervous system; there is a diminution in the emission of N-rays in paralyzed or atrophied muscles in myopathic and other cases. Charpentier and Meyer have found that the intoxication and curarization of certain nerves produces a perceptible effect upon the radiation of N-rays by the muscles which they control. Jegou has found that any wire carrying an electric current emits N-rays; a simple means of obtaining N-rays is to take a Leclanche cell and to close the circuit for some time. The N-rays are stored in the liquid, which becomes a powerful source of the same.—*Comptes Rendus*, February 22; Lond. *Elec.*, March 11.

N-Rays.—BLONDLOT.—An account of an experimental investigation of the dispersion of N-rays and a measurement of their wave lengths. A beam of N-rays, when subjected to dispersion by means of an aluminum prism, is dissolved into several beams corresponding to different indices of refraction. The wave lengths of the N-rays were found to be much shorter than those of light.—*Comptes Rendus*, January 18; translated in Lond. *Elec.*, March 11.

Stresses in a Magnetostatic Field.—WALKER.—A (Brit.) Physical Society paper referring to the observation made by Quincke that when a glass bulb containing a solution of ferric chloride was placed between the poles of a strong electromagnet, the level of the liquid in a capillary attached to the bulb, fell. This has generally been held to require for its explanation a system of stress which differs from the magnetic stresses of electrical type. The present author endeavors to show that the experiments can be quite well explained by the stresses of the electrical type.—Lond. *Elec.*, March 11.

REFERENCES.

Resistance and Temperature.—KÖNIG.—An article giving the simple formulas for calculating the change of electric resistance with temperature. He also gives a simple diagram which enables one to quickly read of the temperature variations of copper resistances. —*Elek. Anz.*, March 3.

Radium.—DANNE.—The first of a series of articles on radium salts; the present portion deals with their preparation and properties, some interesting illustrations being given.—*La Nature*, March 5.

ELECTRO-CHEMISTRY AND BATTERIES.

Ferro-Nickel from Pyrrhotite.—SJOESTEDT.—An illustrated account of experiments made at Sault Ste. Marie on the production of ferro-nickel direct from the Sudbury nickeliferous pyrrhotite. Experiments were made to subject the roasted fines to electric smelting and an electric furnace was erected for this purpose, in which a ferro-nickel pig iron was made from a poor roasted pyrrhotite, with about 3 per cent. sulphur and 53 per cent. iron, at the rate of 60 pounds per hour, with an electrical energy of 108 kw. This is equivalent to 225 gross tons per year, corresponding to an expenditure of 230 hp per ton-day. With a furnace of 300 to 500 hp, which would be more economical, 180 to 200 hp would probably suffice for obtaining a gross ton of metal. But even at that rate the intended plant for the manufacture of 50 tons of ferro-nickel pig per day would have required an electric installation of 10,000 hp, which meant more time and expenditure than were considered necessary. It was, therefore, decided to dead roast the ore, briquette the roasted fines and convert the briquettes, together with an addition of non-nickeliferous iron ores, by the ordinary blast furnace process, into a pig of desired nickel contents.—*Iron Age*, February 13.

Electro-Analysis.—HOLLARD.—A Faraday Society paper on some applications of the theory of electrolysis to the separation of metals from one another. He discusses three different principles and gives examples of their particular application. The first is to reduce the resistance of the bath by suppressing the formation of gas at the anode, either by introducing a reducing agent at the anode or by the use of a soluble anode. As an application the separation of zinc from nickel is discussed. The second method is based on the use of a metal for the cathode which prevents the liberation of hydrogen since it has a higher overvoltage for the production of hydrogen than other metals. The third method consists in preventing a certain number of metals from precipitating themselves upon the cathode by bringing them into the state of complex salts, the separation of antimony and tin in a concentrated solution of sodium hydrogen sulphide being an example of this principle.—Lond. *Elec.*, March 11.

Electrochemical Developments.—BLOUNT.—The first of the series of Cantor lectures. He stated that the electrochemical industries appear at present to pass through a transition stage. Of those processes which are already of practical utility, copper refining is the most important. Competition between chemical and electrochemical manufacturers is extremely beneficial, since it tends to stimulate workers in both fields to further exertion. As a result, any electrochemical process for using substances which can also be produced chemically is in a more flourishing condition than one which forms the sole basis of manufacture. Pure carbonates can only be produced electrolytically and, therefore, this particular branch is not in quite so healthy a condition as it might be. For copper refining, he believes the multiple system to be better than the series system, although much depends upon convenience. To make a process commercially successful it is necessary to employ a high rate of deposition. In the Dolphin plant good circulation is effected together with the free admixtures of air with the electrolyte, and a current density of 25 amp. per square foot is used. For producing zinc electrolytically, he considers the prospects of obtaining it from a fused salt as good. "The electrolytic winning of lead he considers as absolutely hopeless; while the winning of zinc might be large, but the refining, never."—Lond. *Elec.*, March 11.

REFERENCE.

Concentrated Solutions.—JONES AND GETMAN.—A long account of an experimental study of the molecular lowering of the freezing point of water produced by concentrated solutions of electrolytes. The authors find that, with but few exceptions, electrolytes in general give abnormal molecular depressions of the freezing point in concentrated solutions. They conclude that in concentrated solutions there is combination between the molecules of the dissolved substance and the molecules of the solvent, thus removing a part of the solvent, as far as freezing point lowering is concerned. To explain the conductivity result it is also necessary to assume that there is a certain amount of electrolytic dissociation, together with the hydration, existing in these solutions.—*Phys. Rev.*, March.

UNITS, MEASUREMENTS AND INSTRUMENTS.

Determining the Coefficient of Mutual Induction.—TROWBRIDGE.—A description of a very simple method of determining the coefficient of mutual induction. It is based on the following principle: Two coils of mutual inductance, M, and of self-inductances, L_1 and L_2, when joined in series with the windings in the same direction are equivalent to a single coil of a self-inductance, $L' = L_1 + L_2 + 2M$. When the coils are joined in series so that the lines of force from one oppose the lines from the other, the system is equivalent to a single self-inductance, $L'' = L_1 + L_2 - 2M$. The two coils (provided with a commutator for reversing the direction of the current through one of them) may be put in one branch of a Wheatstone bridge, the other branches of which consist of two non-inductive resistances and a variable standard of self-induction. A balance for steady currents and for variable currents being obtained when the currents are in the same direction through the two-coil gives L'. Repeating the balancing, when the currents are in opposite direction, gives L''. Thus we get M directly as one-fourth the difference between L' and L''. This method, which is very exact, depends on the availability of a variable standard of self-induction. If such a standard is not available, the determination of M may be effected as follows. A coil of a self-inductance L (preferably intermediate between L' and L'') is prepared and by the bridge method the ratios of L' to L and of L'' to L may be found—calling these p and q, respectively, M becomes $\frac{1}{4} L (p - q)$. If L be determined by balancing against electrostatic capacity, then M may be calculated, since p and q are numerical expressions obtained by the use of the bridge. —*Phys. Rev.*, March.

Magnetograph.—WATSON.—A (Brit.) Physical Society paper in which he describes an instrument resembling in principle the Threlfall quartz-thread gravity balance. The principle is to have a magnet suspended on a horizontal quartz fibre kept stretched by means of a spring. The center of gravity of the magnet and the torsion of the fibre are so adjusted that the axis of the magnet is always horizontal. Any variation of the vertical force produces a rotation of the magnet about the fibre, which can be suitably recorded by means of a mirror attached to the magnet. The temperature compensation is effected by weighing the magnet on the same side of the axis of the fibre as the south pole, so that the magnetic couple and the couple due to the torsion of the fibre act in the same direction. Hence, since an increase in temperature causes one of these doubles to decrease and the other to increase, by suitably adjusting the weight and, therefore, the magnitude of the torsion couple, complete compensation can be obtained.—Lond. *Elec.*, March 11.

Electro-Thermometer.—CALLENDAR.—An account of his second lecture on electrical methods of measuring temperatures, the first lecture having been abstracted in the Digest last week. One of the physical problems which can be solved by the application of the electric thermometer is the determination of the absolute expansion of mercury; although this has been done previously, the results require verification, and the author intends to carry out investigations in this direction, using a mercury column 60 ft. long in conjunction with a platinum resistance thermometer. For determining the expansion of various other materials with the temperature, the electrical methods are likewise very convenient; also for determining the latent heat of solutions, for measuring the specific heat of water and steam, for observing the lowering of the freezing point of ice under pressure, and for determining the temperature of steam at different pressures, etc.—Lond. *Elec.*, March 11. A very complete illustrated account of the first lecture of Callendar is given in Lond. *Eng'ing*, March 4.

TELEGRAPHY, TELEPHONY AND SIGNALS.

Type-Printing Telegraph.—SIEMENS.—A very long illustrated paper read before the Berlin Electrical Society on the new high-speed type-printing telegraph of the Siemens & Halske Company. The type printing is done by a photographic method, as shown in Fig. 1. On the rim of the type wheel the 45 different letters and types are cut out at uniform distances on the periphery. This type wheel revolves between an electric spark-gap, *F*, and a sensible strip of paper, *P*. If a certain letter is between the spark-gap and the sensible paper, the arc will send its light through the letter, which

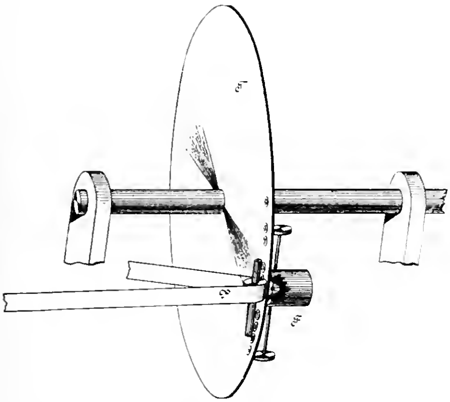

FIG. 1.—TYPE PRINTING TELEGRAPH.

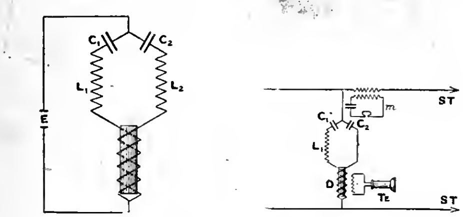
is cut out in the wheel, and the letter will be printed on the paper strip. Since the time of the electric spark is smaller than one-millionth second, the paper strip can be moved at practically any speed without distorting the letter. The receiver and transmitter are operated as two apparatus always revolving in exact synchronism at a speed up to 2,000 r.p.m., or even more. In every revolution one letter may be printed so that 2,000 letters can be transmitted per minute. For every letter transmitted, the transmitter has to send out two current impulses, one positive and one negative, which act on a relay in the receiving station. By the negative impulses one of nine group condensers of the receiving apparatus is charged, while by the positive impulses the condenser is discharged at that place which corresponds to the desired letter. The apparatus is described in detail and profusely illustrated.—*Elek. Zeit.*, March 10.

Simultaneous Telegraphy and Telephony.—Brune and Turchi.—A description of an instrument called a separator, by means of which any existing telephone circuit, whether using earth return or metallic return, can be utilized for simultaneous telegraphic and telephonic messages. The separator is constructed on the principle illustrated in Fig. 2, where *E* is the source of alternating current



FIGS. 2 AND 3.—SIMULTANEOUS TELEGRAPHY AND TELEPHONY.

and the circuit divides itself into two branches of inductances, *R*, and capacities, *C*. If this circuit is traversed simultaneously by two superimposed sine currents of different frequencies and the constants of the circuit are so regulated that there exists a certain relation between the one frequency and the inductances and capacities, then only the current of the other frequency will give rise in the core to a resultant flux, differing from zero, and the effects of the two currents are thus separated. Fig. 3 illustrates the manner in which this system would be utilized for sending one telephonic and two telegraphic communications simultaneously over the same metallic telephone line, *m* being the microphone, *Te* the telephone and *St* the telegraphic station.—*Nuovo Cimento*, October, 1903; abstracted in Lond. *Elec.*, March 11.

Telephony in Great Britain.—A long editorial stating that there are indications that the telephone industry in Great Britain is approaching a crisis. There are at present governmental, municipal and private company telephone systems, but up to the present telephony has not been one of the most successful industries in England; some of those who are carrying it on are doing so at a loss, while others are just making it pay its way. The reason is thought to be that those connected with telephony feel that its present basis is not sufficiently firm. The position of competing telephone concerns must necessarily be insecure, for telephony is, in the nature of things, a business in which competition cannot continue to exist.—Lond. *Elec.*, March 11.

Wireless Telegraphy.—Mees.—An elementary and very clear description of the fundamental principles on which wireless telegraphy is based. The action of electric waves is explained by means of the analogy with a tuning fork.—*Rose Technic*, March.

New Books.

Cours D'Electricité. By H. Pellat. Paris: Gauthier-Villars. 2 volumes. Vol. I, 329 pages, 145 illustrations; price, 10 francs. Vol. II, 522 pages, 221 illustrations; price, 28 francs.

These volumes treat successively of most of the essential subjects in an academic course of electricity; the outstanding matters of electrolysis, electro-capillarity and kindred phenomena will be dealt with in a forthcoming volume. It is evident that M. Pellat's audience at the Sorbonne consisted more of men already familiar with the subject and anxious to hear it expounded by a recognized authority, rather than of ordinary college students looking for the usual sequence of subjects with its strict didactic form and goodly array of mathematical symbols.

M. Pellat is always very lucid in his exposition even of the more recondite phenomena: he also makes a good defence of his somewhat radical departure from the time-honored orthodox mode of treatment. Thus, at the very outset, he admits the importance of Coulomb's law, but declines to use it as the basis of his treatise on electrostatics because of its inapplicability to heterogeneous media. As usually written, the law of force is $F = \frac{1}{K} q_1 q_2$. The constant, *K*, shows that the medium must be homogeneous; for, if not, the force may not act along the line joining the two point charges and may not vary as the inverse square of the distance.

Again, we find the opening chapter of Vol. II devoted to electrodynamics, whilst permanent magnets, electromagnetism and electromagnetic induction follow later on. The reasons assigned for this inversion of customary order are that it tends to simplify calculations, leads to a shorter mode of treatment, and, above all, shows up the real meaning of what is called "quantity of magnetism," which the author emphatically holds to be a mere mathematical concept corresponding to nothing real in nature.

One likes such passages as: "The idea of a force existing between two bodies at a distance from each other without an intermediary is too repugnant to common sense to be admitted." "Newton did not say that the heavenly bodies attract each other, but that "everything takes place as though they do." Gilbert's *De Magnete* is spoken of as "a remarkable work on the mutual action of magnets." Boyle is credited with the introduction into scientific nomenclature of the term *electricity*, whereas it was first used by Charleton in his *Ternary of Paradoxes*[1], page 97, published in 1650, when Boyle was in his 24th year. Previous to the coinage of the term by Charleton, the adjective form was in use; thus, we had a *motus electricus*, *vis electrica*, *corpora electrica*, and the like.

Our author attributes the discovery of the Leyden jar to Dean von Kleist and takes care to note that it was due to a mere accident; further on he adds that it was rediscovered in a similar haphazard way by young Cunæus while working in the laboratory of Van Musschenbroeck in the University of Leyden. Though this is by no means improbable, yet the good luck of Cunæus has often been discredited.

The principle of the electrophorus is ascribed to Wilcke, of Stock-

[1] See Wheeler Collection in the Library of the American Institute of Electrical Engineers.

holm, in 1762; but the apparatus, as we have it to-day, is unquestionably Volta's, belonging to the year 1775.[2]

A few omissions occur in the development of the old frictional machine, which, if supplied, the following would be the main points in its evolution: The original globe of sulphur of Von Guericke was replaced by one of glass by Hauksbee. In turn, this was changed for a glass cylinder by Gordon, a Scotch Benedictine monk, then professor at Erfurt, Germany, while Winckler, of Leipsig, substituted a leather cushion as a rubber in lieu of the hand of the operator. Canton improved the action of the rubber by covering it with an amalgam of tin and mercury. Sigaud de la Fond had a plate machine constructed in 1756, which was greatly improved some years later by Ramsden, of London.

Much space is given to the theory and operation of the Holtz machine, a few paragraphs only being devoted to the Wimshurst, which, invented in 1881, is now rapidly replacing its famous prototype.[3]

The Wimshurst machine is rightly said to be practically independent of all atmospheric conditions, to which priceless advantage the author might have added two others, viz.: that it is always self-exciting when the contacts are clean, as they ought always to be; and that it never indulges in the provoking idiosyncrasy of changing its polarity during a lecture.

As to its reversibility, the late Mr. Wimshurst was in the habit of illustrating this essential feature of influence machines to his friends in his laboratory on Clapham Common, London, by sending the current from one of the larger machines into a very small one, which then acted as a motor and did so very satisfactorily. It would be interesting to know if the statement one sometimes hears is really true, viz.: that the current from, say, a 20-in. Holtz or Wimshurst machine will drive one of similar dimensions as a motor.

Electrical readers are aware that M. Pellat has done excellent work in determining the dielectric constant (K) of paraffine and ebonite; Vol. I, Chapter IX, contains an account of his method and of the apparatus which he used.

In Vol. II we notice with pleasure a description of the elegant method introduced by our own Steinmetz for determining the intensity of the current in alternating circuits; it is a well-deserved tribute to American talent and originality.

Only brief reference is made to the discoveries in radioactivity by Becquerel and the Curies. The fractionization of the atom by J. J. Thomson and the electronic theory of Lodge are not even mentioned; such reticence may, however, be overlooked in view of the author's eloquent insistence throughout on the grand, fruitful work of Clerk Maxwell.

"Annuaire" for the year 1904. Published by the Bureau des Longitudes. Paris: Gauthier-Villars. 850 pages, illustrated. Price, 1.50 francs.

This little volume appears for the first time in divided form. Hitherto it has contained not only astronomical, physical and chemical tables, but also geographical and statistical tables. The yearly increasing matter in every department has rendered it necessary to publish these two divisions of tables on alternate years. This year the astronomical, physical and chemical tables appear.

It is wonderful how much matter is condensed into so small a volume. The first hundred pages relate to calendars. The Gregorian, Russian, Jewish, Mussulman, Roman, Chinese and French Republican calendars are all given. Then follow a number of astronomical tables, occupying 250 pages. More than 300 pages are devoted to condensed tables of densities, specific heats, elasticities and other physical and chemical data.

At the end of the book are two interesting special chapters. They relate respectively to the results of the International Geodetic Conference, held at Copenhagen in August, 1903, and to an elementary explanation of the phenomena of the tides. Electric units receive a special chapter from M. Cornu. The terrestrial magnetic elements for a number of towns and cities in France are also tabularly stated. At Paris, for example, on the 1st of January, 1904, the horizontal intensity is given as 0.1984 gauss, the dip 64° 44′ and the declination as 14° 36′ W.

The tables of the book are very valuable, not merely because they are in clear and compact form, but also because they are official, and represent the data accepted by the French Government. An official value of a quantity is often a very useful one, altogether apart from the question of relative accuracy.

The book is naturally not free from errors of oversight. For example, in defining longitudinal extension, an area is expressed in millimeters, where clearly square millimeters is understood. But the authors are to be congratulated upon the great compactness and extensiveness of the data set forth.

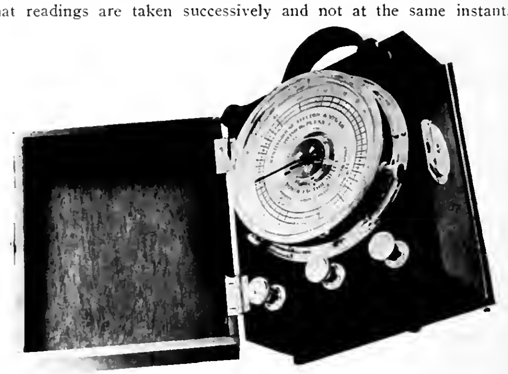
New Portable Power-Factor Meter.

The ordinary method of ascertaining the power factor of a polyphase circuit by means of a comparison of the output in watts with the indicated volt-amperes—a quantity obtained by the multiplication of the indicated voltage by the indicated ampere output—is open to serious criticism. In addition to the tedium and inconvenience involved in making three observations, a multiplication and a division, there is an evident liability to error caused by the number of operations required to obtain the result, which is increased by the fact that readings are taken successively and not at the same instant.



PORTABLE POWER-FACTOR METER.

The inaccuracy of such a method is demonstrated by the fact that by its use there may be shown a power factor of over 100 per cent.

It has been found possible to avoid errors and to simplify the process of determining the power factor of a polyphase circuit by employing a single instrument which indicates directly upon a scale the power factor of a circuit, which reproduces on the dial by the position of a pointer, the angle of phase difference, and gives the actual power in percentage of the apparent power. Such an instrument made in suitable form for testing purposes is shown in the accompanying illustration of a new portable power factor meter made by the Westinghouse Electric & Manufacturing Company. It operates with equal facility and accuracy on either a leading or lagging current, and indicates whether the current leads or lags, whether power is delivered to or by the circuit, and the power factor.

In principle it consists of two sets of coils, one of which contains a separate series winding for each of the phases in the circuit, and the other a potential winding which is connected across one phase of the circuit. The series coils are so arranged as to produce a resultant rotating field. A small iron vane passing through the poten-

[2] Volta's condensing electroscope was destroyed in the fire at Como in 1899; one of his "piles" was saved.

[3] James Wimshurst was born in London in 1832, where he died on January 3, 1903. In 1898 he was elected Fellow of the Royal Society.

tial winding forms movable pole pieces for this winding, which take up a position in the rotating field depending upon the phase relation of the currents producing this field and the voltage impressed upon the potential winding. The pointer attached to the shaft carrying the movable vane indicates on a scale the angle between the current and the voltage, the scale being so graduated as to read directly in power factor. Should the power factor of the different phases differ from each other, the instrument will indicate the average power factor.

Different instruments are provided for two and three-phase circuits. They are made with the same care and accuracy that is employed in the manufacture of the other Westinghouse testing instruments, are finely finished and provided with covers which are made removable for convenience in use.

Another Large Concern to Build Steam Turbines.

Another large engine building concern is entering the turbine field, the Hooven-Owens-Renschler Company, makers of the Hamilton Corliss engine at Hamilton, Ohio, having so decided. A 1500-kw horizontal turbine is now under construction at the company's extensive shops. It is intended to exhibit this machine at the St. Louis World's Fair.

A 600-hp compound condensing Hamilton Corliss engine has been ordered by the Bayshore Terminal Company of Norfolk, Va. It will be direct connected to a direct-current Westinghouse generator of 400-kw capacity. An engine of similar capacity is also to be installed on the New York and Hudson River Railway and Ferry Company at Edgewater, N. J. The generator will also be of Westinghouse build. A 300-hp engine has been requisitioned by the Chambersburg and Gettysburg Electric Railway Company, of Chambersburg, Pa. This will be a belted machine.

Electromagnetic Track Brake.

A new electromagnetic brake has been developed by the British Thomson-Houston Company, which we illustrate herewith. The brake consists of a cast-steel shoe suspended from a bracket fastened to the side of the car truck. This bracket is well ribbed and braced, and provided with heavy lugs, which take the thrust of the brake through cast-steel links in compression. The bracket is formed to act as the seat for two compression springs, which support the brake proper by wrought-iron eye-bolts. These springs keep the brake-shoe free from the track when it is not in operation.

The brake-shoe itself consists of a heavy steel casting with a cored recess, into which the magnetizing coil, which is energized by current from the motors acting as generators, is placed. A brass cap or cover is placed over this coil, and so fitted as to form a water-tight protection to the coil. A steel core extends through the coil providing magnetic circuits, which are completed by sections of rail under the end of the coil.

The terminals of the magnetizing coil consist of insulated flexible wires, brought out through bushed holes in the top of the cast-steel frame of the shoe. They consist of two wires in duplicate, and are

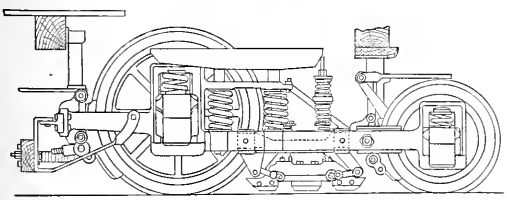


FIG. 1.—DIAGRAM OF TRACK BRAKE.

of sufficient length to extend from the end of the coil winding to the car underframing without a joint.

Each shoe is provided with wearing plates for contact with the rails. These plates are steel castings, held in place by machined bolts, so placed that the plates may be renewed without removing the brake-shoe from the truck.

The brake has been developed in two different forms. The first consists of a large shoe with a bracket designed to suit the various types of single trucks. Two shoes of this type constitute a set, the windings being connected in parallel. This insures protection against failure due to an open circuit. The second is designed for double-truck cars, four shoes per car constituting a set, one shoe being attached to each side frame of each truck. The operating coils of the two shoes on one bogie truck are placed in series, and these are placed in parallel with the two on the other bogie truck. Thus in case of injury to any one shoe or coil only half of the braking effort of the car would be rendered inoperative.

Following are the results of some tests made with the brake, which were carried out under actual working conditions on one of the

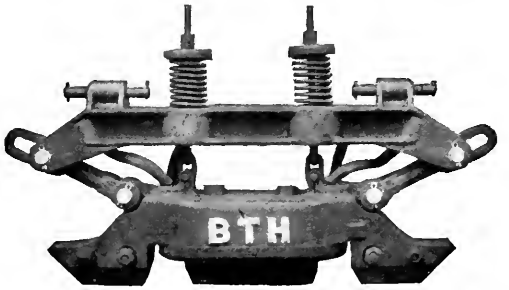

FIG. 2.—TRACK BRAKE.

heaviest routes in England. A four-wheel, double-deck car, with two motors, was used, with the following results on emergency stops:

Speed on applying brake.	Time to stop.	Distance to stop.	Grade Down.
25 m. p. h.	4 seconds	25 yards	1 in 13
14 m. p. h.	1.6 "	5.3 " Level	1 in 14

The first test represents extreme conditions, such as a car running down a steep incline, and considering the grade and the high speed the stop was very rapid, being made in about two and one-half car lengths. The second test would correspond to the case of a car traveling at a moderate speed and obliged to pull up suddenly; it will be seen that such a stop can be made in less than a car length.

SPEED REGULATION DESCENDING GRADES.

Speed maintained.	Grade.	Current per motor.
5 m. p. h.	1 in 13	4 amps.
	1 in 14	
5 m. p. h.	1 in 17	3.5 "
5 m. p. h.	1 in 45	2 "

The second table is interesting inasmuch as it shows that a low and even speed can be maintained when the car is coasting down the steepest grades, so that it is always under perfect control. If necessary the car can be brought to a stop by further movement of the controller handle and held at rest by the wheel brake.

Hauling-in Heavy Cables.

The Knickerbocker Construction Company, 15 Cortlandt Street, New York, has acquired the right to use the Grinnell patent hauling machine and all the devices connected with it. The principal feature of this machine is a chute or guide for the hauling rope, which is connected with the hauling machine extending to the opening at the duct. The rope coming from this guide goes around sheaves on the machine, which insures a perfectly uniform pull entirely regulated by the man operating and without any of the surge usual on capstan and windlass work.

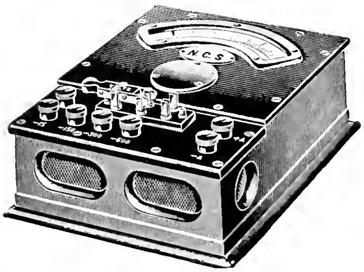
By this arrangement any obstruction in the duct can be felt by the man operating as readily as if he was pulling directly by hand. When the end of the cable reaches the manhole, pulling is continued around the chute without making a separate hitch on the cable until sufficient is in the manhole for splicing purposes. The pull while perfectly uniform can be instantly regulated from nothing to a speed of 40 ft. per minute on the ordinary heavy cables.

By the use of this machine the work can be accomplished rapidly without any chance of injury to the cable. By the continuation of the method of hauling into the manhole and carrying the cable up around the large sheaves of the machine, cables can be hauled out without injury to them and placed on the reels ready for hauling in elsewhere. On the smaller machines gasoline engines are used, and on the larger ones steam engines.

English Portable Testing Set.

The demand for a testing set suitable for use in an engine room and one that can be placed anywhere and be free from the danger of erroneous readings resulting from stray fields, led Nalder Bros. & Thompson, Limited, of London, to produce the instrument illustrated herewith. The instrument is of the moving coil type, and is dead beat. It is fitted with a white enamelled metal scale and a metal mirror. The screening of the instrument has received very careful attention, and is stated to be so efficacious that it is almost impossible for the reading to be affected, even if it be placed quite close to a dynamo or motor.

The voltmeter resistances are carried in the instrument itself, and



PORTABLE TESTING SET.

the current shunts in a separate case. Measurements up to 1,500 amp. and 600 volts can be made, and, as a double-pole change-over switch is provided, resistances can be measured by the practically simultaneous observation of current potential difference. The pressure required to deflect the pointer to the top of the scale on the ammeter side (terminals *AA*) is .12 volts, and, as the scale is divided into 120 divisions, each division corresponds to .001 volt, so that the fall of volts on rail joints, etc., can be tested conveniently. The current shunts are of a new design, and very convenient for connecting, in addition to which they are light. A complete set up to 600 amp. can be carried in quite a small box.

Oil Circuit Breakers.

The use of circuit-breakers as a means of protecting the car equipment from dangerous overloads has become quite general and has led to the development of several different types of breakers designed especially for this class of service. The oil car circuit-breaker shown in the accompanying cut, manufactured by the Hartman Circuit-Breaker Company, of Mansfield, Ohio, is designed to take the place of the fuse block and hood switch on the car. It automatically opens the circuit in case of overload or short-circuit and it can be operated by hand as readily as the usual hood switch.

The switch and current-carrying parts are immersed in oil within a tight cast-iron case. The feature of oil insulation permits of more compact and simple construction than is possible with the usual magnetic blow-out type. The distinctive feature of the circuit-breaker, however, is the use of a series break, consisting of five double-break plug contacts connected in such manner as to give ten breaks in series. The circuit is broken simultaneously at ten distinct points, and the break taking place in oil there is absolutely no destructive arcing, and the circuit-breaker will open quickly and safely on the severest overloads.

The operating mechanism is very simple and consists of a vertical rod, to the lower end of which are attached the movable bridging contacts. The rod operates in a brass bearing and is controlled by a toggle. A slight turn of the handle will cause the toggle to straighten out, thus raising the contact rod and effecting the closing and locking of the switch. The tripping coil is immersed in oil within the case, and, when an overload occurs, the plunger or core operating within the brass tube of the solenoid delivers a strong hammer blow against an extension of the lower joint of the toggle, throwing the toggle out of center and effecting the opening of the switch. Ample space is provided between the live parts of the switch and the cast-iron case, and, as an additional precaution against grounding, the case is lined with insulating cement. Connection to the outside circuit is made within the case by means of insulated cables.

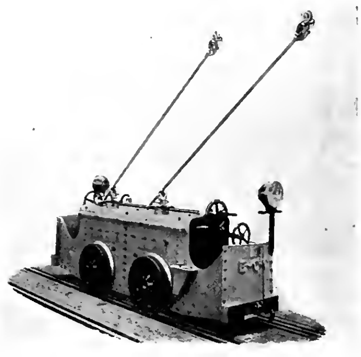
While the circuit-breaker was primarily designed for car service it is also well adapted for switchboard use. It is usually placed on the back of the panel with the handle rod projecting through

CIRCUIT BREAKER.

the board, and the circuit-breaker is opened or closed by hand from the front of the board. The circuit-breaker is also especially well adapted for the protection of motors in mills and factories, for the reason that it is not affected by damp and dirty locations, and there being no exposed current-carrying parts, the circuit-breaker is never a source of danger to those who may be working in the vicinity.

Mine Locomotive.

The accompanying illustration shows an electric locomotive for mine and tunnel work recently designed by the Electric Construction Company, of London, and Wolverhampton, England. Owing to the space limitations in this class of work machines to be adapted to the conditions must be small and compact. In this particular instance



MINE LOCOMOTIVE.

the locomotives were specified not to exceed 3 ft. in width, 3 ft. 4 in. in height, as the tunnel is only 6 ft. high at its maximum point.

The total weight of a complete locomotive of this type is about 4½ tons. It is capable of hauling a load of 35 tons at a speed of 5 miles to 6 miles an hour, but when running light it can attain 10 miles an hour. It is fitted with two motors, each having a normal capacity of about 12½ hp. They can be controlled from either end. Ordinary hand brakes and also emergency brakes are provided.

Power is conveyed to and from the locomotive by two overhead wires.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—There was considerable activity in the stock market and strength in prices on the announcements regarding the practical winding up of the Northern Securities Company. This naturally affected the rest of the list to a greater or less extent. Later in the week some uncertainty seemed to prevail as to the distribution of the Northern Securities' assets so far as its holdings in Northern Pacific and Great Northern were concerned, the effect of which was to cause a rather sharp decline in prices throughout the list. On Friday, however, the market recovered its tone and there was a renewed advance. Excepting these stocks there were no important developments. There was more or less renewed bullish manipulation in Amalgamated Copper. Among the industrial stocks the most important change was that in Allis-Chalmers preferred, the result of the week's trading being a net loss of 10½ points, the closing quotation being also the lowest, namely, 39½. This stock touched 48 during the week. The common stock closed at the highest figure of the week—8⅜—this being a net gain of ⅜ point. General Electric made a net gain of two points, closing at 166, ex-div., while Westinghouse common lost 1½ points, closing at 161½, which was also the lowest price of the week, the highest being 166. In the traction list there was considerable activity in trading in Brooklyn Rapid Transit, the total number of shares dealt in being 142,360. This stock fluctuated between 42¾ and 44¾, closing at 43¼, this being a net loss of ⅝ point. Metropolitan Street Railway was also active as to trading, 35,475 shares being sold at prices ranging between 110 and 113¼, the closing quotation being 111, ex-div., this being a net gain of one point. Western Union kept quite steady throughout the week, closing at 88¼, this being a gain of ⅛ point. On the curb there was a fair demand for investment issues, with generally higher prices for the entire list. Following are the closing quotations of March 29:

*Asked

ST. LOUIS BELL STOCK.—In order to provide additional capital for the removal in St. Louis of overhead wires, the connection of Southwest Missouri lines, extension of toll service, completion of its systems in the southwestern portion of the State, and the betterment of its urban properties, the shareholders of the Bell Telephone Company of Missouri will, on May 17, vote to increase the capital stock from $4,000,000 to $10,000,000. Treasurer Fritz Nisbet states that the directors will be given power to issue this stock from time to time. The right will be offered present holders of the stock to subscribe to the new issue at par.

NEW GENERAL ELECTRIC STOCK.—The $3,325,000 of new stock, the issue of which General Electric stockholders will be asked to approve at a special meeting on May 10, will leave approximately $4,387,600 stock available for sale to present holders. The authorized capitalization of General Electric is $45,000,000, of which $43,937,400 was outstanding in February, 1903, leaving $1,062,600 in the treasury. This balance, with the $3,325,000 now to be authorized, will make $4,387,600, or practically 10 per cent. of the outstanding capitalization, as it was reported a year ago.

ELECTRIC STORAGE BATTERY REPORT.—The Electric Storage Battery Company reports as follows for the year ended December 31, 1903:

	1903.	1902.	1901.	1900.
Gross	$1,761,058	....	....	$1,447,519
Expenses	352,048	....	....	297,779
Net	$1,409,010	....	....	$1,149,140
Other income	92,581	....	....	168,105
Total income	$1,501,591	$1,113,199	$900,243	$1,317,845
Dividends	812,435	812,427	812,413	....
Surplus	$689,156	$300,772	$87,830	....

The condensed balance sheet of the Electric Storage Battery Company as of December 31, 1903, is as follows:

Assets:	1903.	1902.
Plant investment	$283,482	$241,279
Treasury stock	1,750,575	1,750,575
Stocks and bonds in other corpor.	2,839,831	2,845,482
Patents, agreements and franchises	13,564,866	13,523,796
Mortgages	71,000	15,000
Cash	357,495	521,503
Accounts receivable	1,500,820	1,004,568
Notes receivable	240,528	47,065
Inv. accts., nat., stk., etc.	707,829	574,329
Total	$21,316,429	$20,532,601
Liabilities:		
Preferred stock	$453,700	$5,000,000
Common stock	17,546,300	13,000,000
Accounts payable	107,011	94,292
Unpaid dividend scrip	1,737	1,737
Sundry liabilities	4,523	4,523
Profit and loss surplus	2,972,632	2,323,354
Res. for plant deprec., bad debts and unfinished contracts	230,522	104,216
Total	$21,316,429	$20,532,601

AMERICAN MARCONI REPORT.—The Marconi Wireless Telegraph Company, of America, issues the following statement as of January 31, 1904:

Assets:	1904.	1903.
Patent rights, good will, etc.	$5,318,494	$5,286,494
Cost of stations, etc.	175,606	139,939
Stock on hand	14,770	31,224
Accounts receivable	31,088	18,382
Cash	22,115	15,432
Furniture and fixtures	1,216	1,204
Treasury stock	582,760	700,000
Organization expenses, salaries, office and station expenses, etc.	85,183	35,468
Total	$6,231,232	$6,228,166
Liabilities:		
Capital stock	$6,190,000	$6,190,000
Accounts payable	17,232	38,166
Notes payable	24,000	....
Total	$6,231,232	$6,228,166

The annual meeting will be held on April 18.

DIVIDENDS.—The New England Telephone and Telegraph Company directors have declared the regular quarterly dividend of 1½ per cent., payable May 16. The directors of the Hall Signal Company have declared a regular quarterly dividend of 1½ per cent. on its common stock and a dividend of 6 per cent. on its preferred stock, payable April 1. The directors of the Cincinnati, Newport and Covington Light and Traction Company have declared the regular quarterly dividend on the preferred stock of 1¼ per cent., payable April 15.

MICHIGAN TELEPHONE BONDS.—A deed conveying all the property of the Michigan Telephone Company to the Michigan State Telephone Company, as the assignee of N. W. Harris, the purchaser under foreclosure, has been filed. There was filed at the same time a first mortgage executed by the Michigan State Telephone Company to the Old Colony Trust Company, of Boston, for $10,000,000 to secure an issue of a like amount of 5 per cent. thirty-year gold bonds.

BOSTON AND WORCESTER TROLLEY.—The Boston and Worcester Street Railway Company has petitioned the Massachusetts Railroad Commissioners for permission to issue $100,000 additional capital stock and also $200,000 twenty-year 4½ per cent. bonds, the proceeds to be used to pay for expenses and new equipment.

KEYSTONE TELEPHONE BONDS.—It is stated that as soon as market conditions will permit, the Keystone Telephone Company, of Philadelphia, Pa., will ask authorization to issue $5,000,000 bonds, of which $3,500,000 will be sold at once.

BRITISH MARCONI WIRELESS.—The report of the Marconi Company for the year ended September 30 last, to be submitted to the annual meeting, shows receipts for the year of £36,376, £10,607 in excess of the general charges.

CUMBERLAND TELEPHONE reports February gross $319,591, as compared with $277,769 last year, with a net gain in surplus of $31,121, the total February surplus being $118,556.

Commercial Intelligence.

THE WEEK IN TRADE.—Retail business has improved somewhat under the stimulus of better weather, and the tone of wholesale and jobbing trade is thereby strengthened. On the whole, however, distribution is not equal to that of a year ago. Other favorable features are the better winter wheat condition, and evidences of further activity and strength in the iron and steel trades. There is more doing in building, but threatened disturbances in labor circles constitute a drawback at several large centers. Country roads are in poor condition and collections are a source of complaint. Railway earnings tend to improve as transportation difficulties are surmounted, and the outlook is that gross receipts for March will show a slight increase over those of the corresponding month last year. There is still complaint of lack of cars, particularly in the coke producing districts. The decisions of the bituminous coal miners not to strike has been a decided element of strength to general business throughout the West. The industrial situation is quite satisfactory, although unrest tends to increase as spring advances. Reports from the Northwest indicate that the lumber cut in that section is much smaller than that of a year ago. In Maine, however, the cut is a good one. It is reported that Minneapolis flour mills have shut down, owing to the decreased demand for flour. Export trade from San Francisco is good with all parts of the world except Hawaii. Recent rains in the lower Mississippi Valley have helped the farmers, who are now actively engaged in planting. Cotton is coming up in Texas, where the winter wheat crop is in good condition. The situation in the metal markets generally is a very satisfactory one. Finished products have improved. Sales of steel rails are more numerous, and transportation companies are buying shop and track materials, an order for 8,000 cars having been placed with Chicago manufacturers. The market at Pittsburg for steel billets and sheet bars is very firm, with a heavy demand. The country's iron furnaces are pretty well supplied with orders up to July 1, and finishing mills have fully three months' production booked. Other metals have been stronger, copper notably so on an increased foreign and domestic demand. Domestic consumers are showing rather more interest, but orders from home sources are still below the average. The lack is, however, off-set by the very large export business which amounts to 15,500 tons so far this month and is expected to reach 20,000 to 21,000 tons for the entire month of March. The closing prices of the week were 12¾ @ 13 c. for Lake: 12⅝ @ 12⅞ c. for electrolytic, and 12½ @ 12¾ c. for casting stock. During the week ending March 24 there were 215 business failures, according to *Bradstreet's* compilation, against 193 the week previous and 175 the corresponding week last year.

INCANDESCENT LAMPS.—It is understood that incandescent lamp makers have been holding convention in Cleveland and New York the last week or two, but the intention and results have not been disclosed. A great many rumors are afloat as to the object and "plan of campaign." One definite statement that is warranted, however, by the conditions known as we go to press is that the Sawyer-Man Company, which is controlled by the Westinghouse Electric interests, has declined to enter the pool, or combination, or whatever it may be, as to policy and prices. Pending authoritative announcements on the general subject, the following from a Cleveland newspaper will fairly serve the same purpose: "Electric lamp manufacturers all over the country have formed an agreement by which prices will be maintained at a uniform rate. The agreement was reached at a meeting of representative manufacturers last week at The Hollenden. There was no suggestion of combination and competition will be as active as before, but by uniting on uniform rates cutting will be eliminated and competition will be determined by quality of products, thereby greatly benefiting the consumer, it is said. The meeting was called to make adjustment of the differences existing between the various companies because of the universal use of patents controlled by the General Electric Company. This concern owned a number of patents for incandescent lamps, but the patents had been in general use by all the manufacturers. The General Electric Company was finally forced to press its claims in self-defense and suits were begun against manufacturers and dealers who had been using the patents. The latter concluded that they had better pay royalties and be sure of their ground, rather than bear the expense of litigation, and such arrangements were made with every lamp company in the country. These companies, in taking the license, agreed to maintain the scale of prices which had been observed by the best established companies for a number of years. This action will not raise the price above that formerly charged for first-class lamps, but will take off the market lamps of unrecognized makes for which, it was claimed, was charged any price the purchaser would pay. The result will be that the purchaser will pay no higher price than formerly and will be sure to incur no liability for damages for infringement of the patents, dealers claim. All suits against the licensees and customers are withdrawn and the arrangements do not affect the identities or the managements of the various companies concerned in the least. The prices are those under which the Edison lamp has been sold. All existing contracts will be filled at the prices prevailing at the time of contract."

SOME C. & C. ORDERS.—The C. & C. Electric Company, 143 Liberty Street, New York, has secured an order for a 300-kw, three-bearing belted generator from the Electric Company of America, Philadelphia. The machine will be used for both light and power purposes in the company's central station plant at Atlantic City, N. J. The Aetna (Ind.) Power Company has ordered one 180-kw and one 40-kw two-bearing generator for light and power use. A 100-kw, direct-connected generator has been called for by the Citizens' Electric Light & Power Company, of Altoona, Pa. The engine will be a 150-hp one, built by the Erie City Iron Works. This outfit is intended for lighting. A generator of 100-kw capacity has been ordered by the National Meter Company for direct connection to a Nash gas engine. This equipment is to be used for lighting the Steeplechase Park at Coney Island. A similar outfit has been ordered for shipment to St. Louis, Mo. Two 40-kw and one 25-kw direct-connected generators have been ordered for the Mechanics' laboratory, University of Pennsylvania, Philadelphia. The engines will be of Westinghouse manufacture. A 12½-kw, also an 18-kw generator, have been ordered by the National Meter Company for direct connection to 20-hp and 30-hp Nash gas engines for the St. Louis exhibition. The Roberts Chemical Company, of Niagara Falls, is to be shipped a 100-kw special generator for direct coupling to an alternating-current motor already installed. This equipment will be used for electrolytic purposes. A 125-kw engine type generator is to be installed in the plant of the Brylgon Steel Casting Company, at New Castle, Del. The engine will be of Harrisburg build. The C. & C. people also report receipt of an order for a number of motors to be used for driving machine tools in the Boston Navy Yard. Three motors have also been ordered through Feer & Clarkson, of Lebanon, Pa., for operating hoists at the Brooklyn Navy Yard.

LAUNCH WORK AT BAYONNE, N. J.—The Electric Launch Company is very busy with a great many orders for various types of pleasure launches and yachts. W. B. Dinsmore, Jr., of New York, has placed an order for a 21-foot electric launch for use on Tuxedo Lake. The success of the electrics at Tuxedo during the past two years has very much interested society, and boating is expected to become very popular during the coming season. Mr. A. Montgomery Ward, of Chicago, has ordered a 30-foot electric launch for use at Oconomowoc, Wis., one of Chicago's most attractive summer resorts. The launch will be of special design so that it can be taken from one lake to the other over an incline railway built by the cottagers, connecting two lakes. Mr. C. A. Grippin, of Bridgeport, has ordered a large electric cabin launch for use at Lake George. The launch will be used for pleasure purposes and also for conveying guests from the railroad station to Mr. Grippin's camp on Cull Bay Point, where for two years he has been building his summer home. A private electric light plant for lighting the residence and charging the launch has been installed. By an ingenious arrangement the residence can be lighted by the electricity in the launch if the electric plant is not running. Mr. Moritz Walther, of New York has purchased a large electric cabin launch for use on Upper Saranac Lake in the Adirondacks. This boat will join a large fleet of electric boats now in use on this lake. A powerful electric searchlight will be furnished the launch, enabling the boat to navigate at all hours of the night.

LORAIN SPECIAL WORK FOR MANILA.—The Lorain Steel Company branch of the United States Steel Corporation has captured the contract for the special work for the Manila electric traction system, in face of severe British competition. The contract, which is valued at about $30,000, calls for delivery of the material May—June. As previously noted in these columns, J. G. White & Co. have the contract for the construction of the system, which is also to light the Philippine capital. An American syndicate composed of Charles F. Swift, of Detroit, Mich.; Ex-President Frank H. Buhl, of the Sharon (Pa.) Steel Company; F. Kimberley, of Sharon; J. G. White, President Smith, of the Pittsburg Securities Company, and other Westinghouse interests, will operate the lines, etc. Westinghouse equipment will be installed in the power station. A contract will be awarded next week for 100 cars.

HUGE CONTRACT FOR ANDERSON SWITCHES.—The Albert & J. M. Anderson Manufacturing Company have secured what is said to be the largest contract for switches ever awarded. The contract was allotted by the New York Edison Co. and calls for special type edgewise switches in the manufacturing of which no less than 58 tons of copper will be used. Delivery is called for in six months. The Metropolitan Street Railway Company of New York has ordered a substantial lot of big service switches. Eccles & Smith, of San Francisco, have sent in a requisition for 3,000 straight line hangers, ears, pull-offs, etc., for use on the new 30-mile Huntington road. The Interborough Rapid Transit Company of New York has ordered 700 heater switches with magnetic blowout. An elaborate switchboard outfit has been ordered for the purpose of testing different kinds of current in the Lamp Testing Bureau, New York. The Anderson people have also got a number of fair-sized orders in hand for their various specialties to be shipped to the British electrical engineering and contracting concern, Robert W. Blackwell & Co., Limited.

THE BALL ENGINE COMPANY, Erie, Pa., has made the following recent shipments: National Tube Works, Pittsburg, Pa., one 800-hp cross compound Corliss engine, direct connected to alternator. United States Coal Company, Dillonvale, Ohio, one 500-hp Corliss direct-connected engine. Whiting Foundry Equipment Company, Harvey, Ill., one 400-hp Corliss direct-connected engine. Continental Coal Company, Jacksonville, Ohio, one 400-hp engine. Steamer "City of Buffalo," Detroit, Mich., one 80-hp direct-connected engine. J. M. Denholm Bros. & Co., Ltd., East Liberty, Pa., one 150-hp direct-connected engine. Leyden Coal Co., Leyden, Colo., one 175-hp engine. Forest Park Highlands Amusement Company, St. Louis, Mo., two 175-hp direct-connected engines. Semet-Solvay Co., Syracuse, N. Y., two 150-hp direct-connected engines. Dilworth, Porter & Co., Ltd., Pittsburg, Pa., three 50-hp engines. Union Ice Company, Bakersfield, Cal., one 350-hp engine. Soldiers and Sailors' Home, Grand Island, Neb., one 75-hp direct-connected engine.

TRANSMISSION IN OREGON.—The Rock Creek Power and Transmission Company of Baker City, Oregon, is installing a plant near that place, consisting of two 400-kw three-phase, 60 cycle General Electric generators, directly coupled to 900-hp water wheels, running at 450 r.p.m. The latter were furnished by the Pelton Water Wheel Company, of San Francisco, and operate under a head of 960 ft. Three 300-kw three-phase transformers raise the voltage to 22,500—at which pressure it is transmitted 27 miles to Baker City, and 17 miles in another direction to adjoining mining properties. A mixed light and motor load has been secured up to capacity of the two generators. The latter will operate during the greater portion of the time in parallel, but a single governor of the hydraulic pattern will control both units. This plant is the most important of its kind in eastern Oregon, and is expected to be in commercial operation the latter part of this coming May.

EQUIPMENT FOR MEXICAN CAR SHOPS.—Now that the Mexican Car & Foundry Company, S. A., has been organized under the concession granted to Isaac M. Hutchison, of Mexico City, contracts for machine tools, which are to be electrically operated, will be let practically immediately for installation in the company's plant to be built about four miles north of the Mexican capital. The initial capacity of the factory will be five cars daily. Later on it is intended to build trolley cars. M. Hutchison is president and general manager of the company. He has represented the Mexican interests of the St. Louis Car Company for some time past. He also looks after the business of the Niles-Bement-Pond Company and A. L. Ide & Sons. About $100,000 gold will be expended for equipment in the first instance. The works will be electrically lighted.

LIGHTING EQUIPMENTS FOR NEW YORK.—The engineering and contracting firm of Mackenzie, Quarrier & Ferguson, 114 Liberty Street, New York, has secured within the past few days several orders for Harrisburg engines to be installed in New York. The Women's Hospital, One Hundred and Tenth Street, is to be equipped with two 150-hp engines to be direct connected to 100-kw Western Electric Company generators, for lighting purposes. Luchow's Restaurant, Fourteenth Street, is to be provided with a 90-hp engine for direct connection to a Western Electric generator of 60-kw capacity, also for lighting use. The Hanover Fire Insurance Company, 34 Pine Street, has ordered a 75-hp engine to be direct connected to a 50-kw General Electric generator. This outfit will be utilized for additional lighting purposes.

AMERICAN BRIDGE COMPANY.—A number of changes are announced in connection with the American Bridge Company. The Eastern and Pittsburgh divisions of the company's business have been abolished, and the plants now embraced in them have been put in charge of Mr. R. J. Davis, as operating manager, with headquarters in the Frick Building, Pittsburg. President Alfred J. Major gives the schedule below for the removal of the general offices of this company from Philadelphia to Frick Building, Pittsburg: March 26, president, assistant to president and operating manager, March 31, auditing department; April 9, treasury department. Notable gains and economies are expected to attend this concentration of effort and management.

EQUIPMENT FOR FLORIDA PLANT.—The Manatee Light and Power Company of Bradentown, Fla., is about to extend considerably its plant, and has just awarded contracts for additional generators and engines. The new machinery to be installed will have a capacity of 700 kw. The generators have been ordered from the Bullock Electric Manufacturing Company. There will be three machines, a 300 kw alternating-current engine type, 60-cycle, 200 r.p.m. generator; one 300-kw 550-volt, 200 r.p.m engine type railway generator, and a 550-volt belted railway generator of 100 kw capacity. The 300-kw generators will be direct connected to engines to be built by the Harrisburg, Pa., Foundry and Machine Works.

EQUIPMENT FOR MEXICAN MINES.—The United Mining and Development Company of America, 66 Broadway, has just let contracts through E. Gybbon Spilsbury, of the E. G. Spilsbury Engineering Company, 45 Broadway, for considerable electrical equipment to be installed in its Mexican property. A water power plant is to be built for the purpose of operating the company's mines. The initial equipment will be about 400 hp. The generator will be of Westinghouse build. A Pelton water wheel will be used. A large lot of machine tools to be electrically operated, have been ordered through Mexican concerns, who represent American manufacturers in the Southern republic.

GILMORE GENERATORS FOR ENGLAND.—The Gilmore Electric Co., of Boston, and Postal Telegraph Building, New York, recently secured a contract for four generators of 80-kw capacity each for lighting an asylum in the vicinity of Liverpool. The generators will be direct connected to Scotch engines. An order for six machines of similar capacity has just been received for shipment to London, where the generators will be used for both light and power purposes.

THOMAS INSULATORS FOR MEXICO.—Thomas & Son, of East Liverpool, Ohio, have been awarded a contract for 40,000 insulators by the Mexican Light & Power Company, Limited, for use in the construction of the Mecaxa-Mexico City transmission system. Various other interesting contracts will be let shortly by the Mexican company, whose New York offices are at 29 Broadway, and of which F. S. Pearson is the consulting engineer.

LIGHTING FOR BLOOMINGDALE STORE.—The Bullock Electric Manufacturing Company, through its New York office, has secured a contract for lighting equipment to be installed in Bloomingdale Brothers Department Store, East Fifty-ninth Street. A 150-kw three-bearing slow-speed belted generator and a 200-r.p.m. engine of 100-kw capacity direct-connected to a Watertown engine have been ordered.

CHICAGO, ILL.—Articles of incorporation will be filed at Springfield, Ill., by the United States Telegraph and Telephone Company. The plan, it is said, is to absorb the National Telegraph News Company of Chicago, the Sempire Clock Company of St. Louis, and the Chicago and Milwaukee Telegraph Company, of Milwaukee.

EQUIPMENT FOR TWENTY-THIRD STREET FERRY HOUSES.—It is proposed to install a plant of about 400-kw capacity for the purpose of generating current to light the new Central, Erie and Lackawanna ferry houses, West Twenty-third Street. Kenneth M. Murchison, Jr., 5 West Thirty-first Street, is now drawing up the plans.

ELECTRIC PUMPS FOR PHILIPPINE DRY DOCK.—The International Steam Pump Company, 114 Liberty Street, New York, has secured the contract for the large electrically operated Blake pumps to be used on the steel dry dock now under construction at Sparrow's Point by the Maryland Steel Company for use in the Cavite Naval Station, Philippine Islands.

WAGNER MOTORS ADOPTED.—The Wagner Electric Manufacturing Company, St. Paul Building, will fill all future power motor requirements for the Public Service Corporation of New Jersey. Under 35-hp the machines will be of single phase type. Above that size the motors will be polyphase.

ROBB ENGINE FOR SCOTCH LIGHTING PLANT.—J. G White & Co., Ltd., of London, has placed an order for a 300-hp Robb engine which is to be installed in the municipal lighting plant at Perth, Scotland.

ELECTRIC ROCK DRILLS FOR NEW ZEALAND.—The Denver (Col.) Engineering Works have secured a substantial contract for electrically operated rock drills for installation in New Zealand mines.

THE PERKINS MACHINE COMPANY, South Boston, Mass., has purchased the Slater Engine Works at Warren, Mass. The Perkins Company manufactures presses, punches, shears, etc.

DIRECTORY OF ELECTRICAL ASSOCIATIONS, SOCIETIES, ETC.

(Published first issue of each month.)

American Electrochemical Society. Secretary, C. J. Reed, 929 Chestnut Street, Philadelphia, Pa. General meeting, Washington, D. C., April 7, 8 and 9, 1904.

American Electro-Therapeutic Association. Secretary, Dr. C. E. Skinner, New Haven, Conn. Next meeting, St. Louis, Sept. 13, 1904.

American Institute of Electrical Engineers. Secretary, Ralph W. Pope, 95 Liberty Street, New York. Meetings, last Friday each month.

American Railway, Mechanical & Electrical Association. Secretary, Walter Mower, 12 Woodward Avenue, Detroit, Mich.

American Society of Municipal Improvements. Secretary, G. W. Tillson, Brooklyn, N. Y. Next meeting, St. Louis, Oct. 4, 1904.

American Street Railway Association. Secretary, T. C. Pennington, 2020 State Street, Chicago.

Association of Edison Illuminating Companies. Secretary, W. S. Barstow, New York City and Portland, Ore.

Canadian Electrical Association. Secretary, C. H. Mortimer, Toronto, Ont. Next meeting, Hamilton, Ont., June, 1904.

Colorado Electric Light, Power & Railway Association. Secretary, George B. Tripp, Colorado Springs, Col. Annual meeting last Wednesday in October.

Connecticut State Street Railway Association. Secretary, E. W. Poole, Bridgeport, Conn. Annual meeting in November.

Engine Builders' Association of the United States. Secretary, D. Fleming, Harrisburg, Pa.

United Electrical Contractors' Association of New York State. Secretary, F. Fish, Rochester, N. Y.

Electrical Trades Society (Member National Electrical Trades Association). Secretary, A. P. Eckert, 39 Cortlandt Street, New York. Board of Directors meets second Friday of each month.

Illinois State Electric Association. Secretary, H. E. Chubbuck, LaSalle, Ill.

Indiana Public Utilities Association. Secretary, A. M. Barron, South Bend, Ind. Next meeting, Indianapolis, Ind., Oct. 18, 1904.

Independent Telephone Association of the United States of America. Secretary, Frank G. Jones, 48 West Jackson Boulevard, Chicago. Next meeting, St. Louis, Sept., 1904.

Independent Telephone Association of Southern Indiana. Secretary, E. W. Pichardt, Huntingburg, Ind.

International Association of Municipal Electricians. Secretary, Frank P. Foster, Corning, N. Y.

Interstate Independent Telephone Association. Secretary, E. M. Coleman, Louisville, Ky.

Iowa Electrical Association. Secretary, W. S. Porter, Eldora, Ia. Next meeting, Des Moines, April 20 and 21, 1904.

Iowa Telephone Association. Secretary, C. C. Deering, Des Moines, Ia.

Kentucky Independent Telephone Association. Secretary, James Maret, Mount Vernon, Ind.

Maine Street Railway Association. Secretary, E. A. Newman, 471 Congress Street, Portland, Me.

Massachusetts Street Railway Association. Secretary, Charles S. Clark, 70 Kilby Street, Boston, Mass. Meets second Wednesday of each month, except July and August.

National Arm, Pin & Bracket Association. Secretary, J. B. Magers, Madison, Ind. Next meeting, St. Louis, July, 1904.

National Electrical Contractors' Association of the United States. Secretary, W. H. Morton, 44 Whitesboro Street, Utica, N. Y. Next meeting, St. Louis, Mo., September 14, 15 and 16, 1904.

National Electric Light Association. Secretary, Ernest H. Davis, Williamsport, Pa. Next meeting, Boston, Mass., May 24, 25 and 26, 1904.

New England Street Railway Club. Secretary, J. H. Neal, 101 Milk Street, Boston, Mass. Meets last Thursday of each month.

New York Electrical Society. Secretary, G. H. Guy, 114 Liberty Street, New York.

Northwestern Electrical Association. Secretary, T. R. Mercein, 85 Michigan Street, Milwaukee, Wis. Next meeting, St. Louis, Sept., 1904.

Ohio Street Railway Association. Secretary, Chas. Currie, Akron, Ohio.

Ohio Electric Light Association. Secretary, D. L. Gaskill, Greenville, Ohio.

Ohio Society of Mechanical, Electrical and Steam Engineers. Secretary, C. J. Miller, Canton, Ohio. Next meeting, Columbus, O., May 13, 1904.

Pacific Coast Electric Transmission Association. Secretary, G. P. Low, 600 Rialto Building, San Francisco, Cal.

Southwestern Electrical Association. Secretary, J. L. Ellis, Oklahoma City, Okla. Next meeting, Dallas, April 25, 26 and 27, 1904.

Southwestern Gas, Electric & Street Railway Association. Secretary, Frank E. Scovill, Austin, Texas. Next meeting, Dallas, April 25, 26 and 27, 1904.

Street Railway Accountants' Association of America. Secretary, W. B. Brockway, 40 Morris Street, Yonkers, N. Y.

Street Railway Association of the State of New York. Secretary, W. W. Cole, Elmira, N. Y. Next meeting, Utica, N. Y., Oct. 11 and 12, 1904.

Vermont Electrical Association. Secretary, C. C. Wells, Middlebury, Vt. Next meeting, Montpelier, August, 1904.

Western Society of Engineers, Electrical Section, Chicago, Ill.

General News.

THE TELEPHONE.

JACKSONVILLE, ARK.—The Jacksonville Telephone Company has been incorporated with a capital stock of $1000. The incorporators are S. W. Murtishaw, W. G. Graham, E. J. McBride, E. C. Stone and Mrs. Emma C. Martin.

ROGERS, ARK.—The Tri-State Independent Telephone Association has been organized, Mr. W. T. Stahl, of Siloam Springs, being president; S. H. Slaughter, of Lafayetteville, vice-president; K. J. Comfort, of Westville, secretary, and W. D. Wasson, of Gentry, treasurer. The association represents independent lines in southwest Missouri, northwest Arkansas and northeast Indian Territory, and its object is the betterment of local and long distance service. A farmers' line service will be encouraged. A meeting of the association will be held in June.

WASHINGTON, D. C.—The District Telephone Company has been incorporated with a capital stock of $1,000,000. The directors are C. S. Walton and J. H. Ralston.

LEWISTON, IDAHO.—A franchise has been granted to the Nez Perce Co-operative Telephone Company to operate and maintain a telephone line in this city.

WYOMING, ILL.—The Fidelity Telephone Company has been incorporated with a capital stock of $25,000. The directors are A. L. Johnston, A. B. Hoff and others.

TREMONT, ILL.—The Tremont Independent Telephone Company has been incorporated with a capital stock of $20,000. The directors are A. J. Davis and W. H. Ames.

WILLIAMSVILLE, ILL.—The Sangamon Telephone Company has been incorporated with a capital stock of $2500. The directors are J. P. Telfer, R. U. Richardson and others.

EAST LYNN, ILL.—The Fountain Creek Telephone Company has been incorporated with a capital stock of $34,000. The directors are W. A. Yeasel, G. H. Wiel and others.

HEBRON, ILL.—The Farmers' New Era Telephone Company has been incorporated with a capital stock of $5000. The directors are George Hunt, L. A. Nichols and others.

JOHNSON CITY, ILL.—The Good Service Telephone Company of Johnson City has been incorporated with a capital stock of $2500. The incorporators are J. E. Poindexter, D. H. Penson and Calvin Dillon.

TROY, ILL.—A license has been issued by the Secretary of State for the incorporation of the Troy Telephone Company, of Troy, Ill. The capital stock is $10,000. Incorporators: J. H. Steinhaus, J. W. Gornett and C. Busse, Jr.

CHICAGO, ILL.—The United States Telegraph and Telephone Company has filed articles of incorporation in this State. Among the incorporators are Col. G. Watson French, of Davenport, Iowa; Henry E. Weaver, H. L. Turner and H. D. Critchfield, of Chicago; Max R. Ortvine and A. B. Hulit, of St. Louis. This probably means the entrance of independent telephone toll lines to Chicago. H. D. Critchfield, one of the incorporators, is general manager of the Automatic Electric Company and closely identified with the Illinois Tunnel Company. It is rumored that the Chicago & Milwaukee Telegraph Company's line will be taken over by the new company.

HANCOCK, IND.—The Coffman-Heller Telephone Company has been incorporated with a capital stock of $120. The directors are G. W. Coffman and others.

FORT WAYNE, IND.—The annual meeting of the stockholders of the National Telephone & Telegraph Company was held here recently and officers were elected as follows: President, Henry C. Paul; vice-president, Charles S. Bash; secretary, William L. Moellering, and treasurer, William A. Bohn. The company operates exchanges in several towns in this part of the State. The financial statement showed that the earnings were satisfactory and exceeded those of last year by several thousand dollars.

RUSHVILLE, IND.—The Rushville Telephone Company held a meeting on March 18 to devise a plan to raise additional capital necessary to extending the lines and purchasing a new and modern switchboard. The company's plant has proven a paying investment, and the 200 stockholders voted that each shareholder increase the amount of his stock. By this plan $32,000 was raised and extensive improvements are now assured. L. C. Lambert, a local capitalist, offered to buy the plant and said he would agree to expend $100,000 on it for betterments during the next ten years.

TAMA, IA.—The Tama Telephone Company has been incorporated with $15,000 capital stock.

STUART, IA.—The Lincoln & Stuart Telephone Company proposes to establish a local exchange.

POCAHONTAS, IA.—The Pomeroy-Palmer Telephone Company has been formed to build a rural line.

PORTLAND, ME.—The Northeastern Telephone Company is preparing to extend its lines to South Windham and Raymond. This company operates an automatic system.

AMBOY, MICH.—The Clear Fork Telephone Company has been organized here.

MILLIKIN, MICH.—The Michigan Bell Telephone Company will build an exchange here.

RED WING, MINN.—D. M. Neill and others contemplate establishing a local telephone exchange.

ST. CLOUD, MINN.—The Clearwater Telephone Company has increased its capital from $10,000 to $25,000.

SLAYTON, MINN.—The Enterprise Telephone Company has been granted a franchise for a telephone exchange.

ST. PAUL, MINN.—The Armstrong Telephone Company will increase its capital stock from $25,000 to $100,000.

MAZEPPA, MINN.—A farmers' telephone line is to be built from Mazeppa covering Bear Valley and Zumbro Falls.

WILLMAR, MINN.—The Lake Andrew & Dover Telephone Company has been formed here by farmers. A 30-mile line will be built.

ST. PAUL, MINN.—The Armstrong Telephone Exchange Company of Truman has increased its capital stock from $25,000 to $100,000.

OVANDO, MONT.—Articles of incorporation of the Big Blackfoot Telephone Company, which will operate between this city and Drummond, have been filed with the Secretary of State.

HANNIBAL, MO.—The Missouri & Kansas Telephone Company is seeking a franchise here for an exchange.

ST. LOUIS, MO.—The Kinloch Telephone Company, of this city, announces that its lines to Carthage and Joplin will be completed by June 1. In the "zinc belt" the independent companies show great increase in earnings.

JEFFERSON CITY, MO.—The Laddonia, Rush Hill & Mexico Union Telephone Company has been granted a certificate of incorporation. The capital stock is $1000. The incorporators are: J. N. Rosser, E. A. Featz, C. L. Stewart, J. C. Maxwell and T. J. Roberts.

ST. JOSEPH, MO.—The Missouri River Telephone Company, with a capital stock of $150,000, has filed articles of incorporation. The company is composed of J. E. Zeluff and Walter S. Dickey, of Kansas City; W. T. Rankin, Frank S. Travis and John R. Stafford, of Tarkio, and Ralph O. Stauber, of St. Joseph.

LINCOLN, NEB.—The Hay Springs Alcova Telephone Company has been incorporated with a capital stock of $25,000.

NEWARK, N. J.—The Newark Telephone Exchange has been incorporated; capital, $25,000. Directors: E. A. Smith, J. E. Pulver, E. P. Thatcher, Newark.

WOLCOTT, N. Y.—The Farmers' Co-operative Telephone Company has been organized here by J. P. Fowler, Fred Brown, S. Sears and others.

ALBANY, N. Y.—The Sherburne Telephone Company has been incorporated with a capital stock of $10,000. The directors are: Jesse H. Shepard, F. G. Shepard, H. A. Shepard, Estella A. Shepard, Charles A. Fuller and Frank C. Cashman.

TROY, N. Y.—The Commercial Union Telephone Company has been organized here for the purpose of merging the Rensselaer Telephone Company of this city, the Saratoga Telephone & Telegraph Company of Saratoga Springs and the new Union Telephone Company of Glens Falls. The new company elected J. T. Christie, president; W. Levis Burke, secretary, and Peter McCarthy, treasurer. It will extend its lines.

BISMARCK, N. D.—The Milton Telephone Company has been incorporated with a capital stock of $10,000.

BOWBELLS, N. D.—A telephone exchange is proposed in this place, Mr. G. L. Bickford being one of those interested in the enterprise.

BORDEN, OHIO.—The Laurel Telephone Company of Borden has been incorporated with a capital stock of $1000 by William R. Jackson, Edwin Packwood, F. M. Vance and E. Ross.

ALLIANCE, OHIO.—The Stark County Telephone Company will establish an exchange at Louisville and will give toll connection with farmers in Harrisburg, Fairport, Pairs and other villages.

GETAWAY, OHIO.—The Getaway Telephone Company, of Getaway, Lawrence County, has been incorporated with a capital stock of $5000, by J. E. Schneider, John W. Gerlach, W. W. Poindexter, W. T. Cox and G. W. Thader.

CINCINNATI, OHIO.—The Council of Norwood has granted a 25-year franchise to the Norwood Citizens' Telephone Company, which is an independent concern. This is regarded as an entering wedge in favor of the admission of independent service in this city.

TOLEDO, OHIO.—What is said to be the largest single extension to a telephone switchboard in America has just been completed at the exchange of the Home Telephone Company in this city. The extension has a capacity of 1000 connections, which bring the total capacity of the exchange up to 7000 lines. The new work was done by the Sterling Electric Company, of Lafayette, Ind., and cost about $29,000, making the total expenditure on account of the switchboard $148,000.

TITUSVILLE, PA.—The Pennsylvania Railroad Company is installing a telephone line on its Chautauqua Division.

EMERY, S. D.—The Tri-County Mutual Telephone Company is seeking a local franchise.

MITCHELL, S. D.—The Dakota Central Telephone Company will build a line from Aberdeen to Mitchell.

GARRETSON, S. D.—A telephone company has been organized to build a local and rural system. A. J. Berdahl is interested.

FORT SUPPLY, TEX.—The Fort Supply Telephone Company has been incorporated with a capital stock of $10,000. The incorporators are: J. T. Brewer, J. P. Gandy, Robert Simis, M. W. Phillips and J. S. Peterson.

CHARLESTON, W. VA.—A charter has been granted here to the Wheeling & Pittsburg Telephone Company, of Wheeling, W. Va., which has been incorporated with a capital stock of $100,000. The incorporators are: J. A. Howard, J. P. Young and F. C. Handlan, of Wheeling; R. C. Hall and J. G. Plant, of Pittsburg.

DALLAS, WIS.—J. A. Anderson is seeking a franchise for a telephone exchange.

GRANTSBURG, WIS.—A telephone company has been formed at Swiss to build a line from Gordon to Grantsburg.

ELECTRIC LIGHT AND POWER.

GURDON, ARK.—The City Council has granted S. Scott Harris and T. L. Hodges a franchise for an electric light and power plant.

WASHINGTON, D. C.—It is reported that certain officials of the government are considering a plan to establish in the vicinity of the west end of the Mall an immense power house from which heat, light and electric power will be supplied to all government buildings in the northwest and southwest sections of the city. The plan at this time has not assumed definite form, but the proposition is being discussed among a number of government officials who seem to favor the project.

ALBANY, GA.—The city of Albany has contracted with the Albany Power & Manufacturing Company for 300 horse-power to be delivered at the city electric light plant at $8000 annually. The power company is developing a big power on Muckafoonee Creek near the city. The matter will be submitted to a vote. The saving to the city is estimated at $3000 or more per annum.

DUQUOIN, ILL.—The City Councils of Duquoin and Pinckneyville have in contemplation the construction of an electric light plant to give service to both places.

RIDGEFARM, ILL.—The matter of issuing $10,000 bonds for a municipal lighting plant is under consideration.

MOROCCO, IND.—H. D. Hallett, of Aurora, is preparing plans for water works and an electric light plant, to cost $26,000.

JEFFERSON, IND.—Local capitalists, headed by Hon. Louis Schneck and George H. Voight, have employed hydraulic engineers to examine Fourteen Mile Creek and the Tunnel Mill property with a view to utilizing the falls for developing power. A company will be formed to establish a power house for generating electricity by water power. The experts say that sufficient fall can be had to furnish 10,000 hp. It is the intention to operate an electric railway connecting this city and New Washington by this power.

CLARION, IA.—The City Council has decided to expend about $6000 in improving the electric light plant.

HOUGHTON, MICH.—The Portage Lake Gas & Coke Company has petitioned for a franchise to establish electric and gas lighting.

KALAMAZOO, MICH.—Application has been made by H. C. Hoagland for a receiver for the Kalamazoo Valley Electric Company. The Kalamazoo Company furnishes power to many factories in Kalamazoo and Battle Creek, and also supplies the power for the operation of the electric railways between Allegan and Jackson.

DULUTH, MINN.—Bids will be received April 11 by the Common Council for $50,000 bonds to be used for extending and improving water and light plant. H. W. Cheadle is City Clerk.

MINNEAPOLIS, MINN.—The effort of the Retail Dealers' Association to bring the Minneapolis General Electric Company and the city council to an agreement on a franchise has come to naught.

CARTHAGE, MO.—The Carthage Heat, Light & Power Company has been incorporated with a capital stock of $100,000, all paid. The incorporators are S. A. Stucky, I. C. Hudson and D. C. Brainard.

HARVARD, NEB.—J. J. Keefe, of York, Neb., has secured the franchise for an electric light plant.

OMAHA, NEB.—The Omaha Electric Light & Power Co. is planning to expend $75,000 in improvements on its plant this spring.

VALATIE, N. Y.—The City Clerk writes that it was voted March 15 to construct an electric light plant.

LOCKPORT, N. Y.—The Lockport Light, Heat & Power Company has been incorporated, with a capital of $75,000.

ALBANY, N. Y.—The Nassau Light & Power Company, which was recently incorporated, has increased its capital stock from $500,000 to $1,500,000.

FT. EDWARD, N. Y.—The Village Trustees have granted a franchise to the Hudson River Electric Company to furnish electricity for power, heat, fuel and lighting purposes.

ALBANY, N. Y.—The Heat, Light & Power Improvement Company of America, of New York, has been incorporated; capital, $600,000. Directors: James P. Lowery, Andrew Ritchie and Charles T. Eldridge, New York.

SYRACUSE, N. Y.—The Syracuse syndicate which owns the controlling stock of the Wayne County Electric Light & Power Company, is anxious to dispose of its interests in the same to business men of Lyons and Clyde.

AMSTERDAM, N. Y.—The Citizens' Electric Company, of Amsterdam, has been incorporated with a capital stock of $50,000. The directors are: William W. Dickson, Frank W. La Chapelle, Maurice G. Walsh, George C. Stuart and W. Fenton Myers, of Amsterdam.

NEW YORK, N. Y.—Bids will be received April 23 by Mordecai T. Endicott, chief of the Bureau of Yards and Docks, Navy Department, Washington, D. C., for installing a turbo-alternator with exciter set, 5 induction motors, 1 motor generator, 2 switchboards and accessories at the navy yard here. Estimated cost, $44,000.

CONCORD, N. C.—The town of Concord has voted to purchase the electric light plant at $8500.

SALISBURY, N. C.—The Salisbury and Spencer Railway & Electric Company has bought the Salisbury Gas & Electric Lighting Company.

WAYNESVILLE, N. C.—B. J. Sloan has contracted to furnish the city of Waynesville with power for light for 10 years, the power to be generated at a falls on Pigeon River, by the erection of a dam. The capacity of the plant will be 1500 horsepower. The city will take at least 125 horsepower at $20 per horsepower per annum.

HAMILTON, OHIO.—The city will issue $5000 in bonds for the purpose of improving its lighting system. Walton S. Powers is secretary.

MARYSVILLE, OHIO.—Mr. McKibben, of Van Wert, is preparing estimate of cost, etc., for an electric light plant. The contract for lighting expires this spring.

CAMERON, OHIO.—The Cameron Pottery Company has made a proposition to the town council to light the streets. The company has recently completed its plant and has more power than it requires.

BEDFORD, OHIO.—Philadelphia, Pa., capitalists represented by E. A. Mandeville and Edw. Roberts, are stated to have purchased the plant of the People's Electric Light Company. It is proposed to enlarge the plant, and install some new machinery.

ZANESVILLE, OHIO.—Hon. C. U. Shryock, of Zanesville, has obtained a franchise from the village of Philo for the construction of an electric lighting plant and water works system. A plant will be erected at Taylorsville Dam where excellent water power will be obtained. The villages of Duncan's Falls and Taylorsville will also be supplied.

MT. VERNON, OHIO.—The city council has passed an ordinance granting a franchise to H. C. Hubbell, C. C. Hubbell and John W. Hawk for an electric light, power and hot water heating system. The rate of current shall not exceed 15 cents per kilowatt and arc lights are to be furnished at $65 per year on moonlight schedule. The plant is to be built at once.

BEAVERDALE, PA.—A charter has been issued to the Beaverdale Electric Light Company, of Beaverdale; capital, $5000. Directors: W. L. Hicks and C. O. Templeton, of Tyrone; C. F. Fraser, of Altoona, and T. J. Gates, of Tyrone.

BUSHKILL, PA.—A charter has been granted to the Bushkill Water Power Company, with a capital of $5000. The company intends using the water to furnish electric power for commercial purposes, and also for a cement mill which the company will erect in the near future.

KNOXVILLE, TENN.—At a meeting of the City Council an ordinance was passed on first reading to put all wires underground. The Council also reported at this meeting favorably on the city owning a lighting plant.

HEMPSTEAD, TEX.—W. P. Lipscomb is reported interested in the construction of an electric light plant.

BARTLETT, TEX.—Plans are being considered for the construction of an electric light plant, to light Bartlett, Granger and Holland.

RICHFIELD, UTAH.—The Clark Power Company has in view a project for establishing a large power plant near here which will supply sufficient power for all the towns in the county. The plant also includes the construction of electric railways.

SALT LAKE CITY, UTAH.—Articles of incorporation of the Shoshone Falls Power & Lighting Company have been filed at Boise. The company is organized with a capital stock of $2,500,000, and bonds of a like amount will be issued. The main promoters are McDonald & McCoy, of Chicago, although Utah and Idaho capitalists are largely interested in the project. The plan is to establish three power plants on the Snake River, where from 80,000 to 100,000 horse-power will be generated, the first plant to be installed at Shoshone Falls. The Utah Light & Railway Company expects to receive, for distribution, about 8000 horse-power, which will relieve it of the criticism it is now undergoing as a result of its inferior lighting service.

RICHMOND, VA.—Governor Montague has signed the bill appropriating $25,000 for the construction of a heat, light and power plant on the Capitol Square.

RICHMOND, VA.—The State Legislature of Virginia has refused to take up the matter of the city of Newport News issuing $100,000 bonds to establish a municipal electric light plant.

TOLEDO, WASH.—The City Council has granted W. A. Gray a franchise for an electric light plant.

BERKELEY SPRINGS, W. VA.—The Cacapon Power Company, of Berkeley Springs, has been incorporated, with a capital of $100,000, to use water power of Cacapon River, in Morgan County, to generate electric power for industrial plants. The company proposes to light both Hancock, Md., and Berkeley Springs with electricity. Incorporators: Morrison Barclay and Thos. Barclay, of Greensburg, Pa., and F. R. Reed and J. H. Siler, of Berkeley Springs.

NEW LONDON, WIS.—The city has purchased the local electric light plant and will make improvements.

MONTICELLO, WIS.—E. W. Van Norman, Village Clerk, writes that it was voted March 11 to issue $8000 bonds for an electric light plant.

QUEBEC, QUE.—Another electric company for the city of Quebec is likely to be formed soon under the name of the Quebec Electric Company. The idea of the new company is to install a hydraulic electric plant at Seven Falls, on the River Ste. Anne, in the county of Montmorency. The company will seek incorporation at the next session of the legislature for power to construct an electric railway from these falls to the city of Quebec by way of St. Paul, St. Joachim, Ste. Anne de Beaupre, Chateau Diver, L'Ange Gardien, Montmorency Falls, Beauport and Limpilpu, and to sell in these places electricity, heat and power.

QUEBEC, QUE.—The amalgamation of the two Quebec electrical companies, the Jacques Cartier Electric Light & Power Company and the Quebec Railway, Light & Power Company, which entered into a secret agreement some months ago, has been publicly announced. The latter company has just issued a circular to its clients, informing them of an increase in the rate of charges for the electric light service. Heretofore, ten cents per kilowatt, with a cash discount of 10 per cent., was charged consumers, and now they are called on to pay 15 cents per kilowatt with a 20 per cent. cash discount, which means a practical increase in the rates of 40 per cent. The result of this increase is that many of the consumers are returning to the use of gas and coal oil.

THE ELECTRIC RAILWAY

BESSEMER, ALA.—Local interests have raised funds for making a survey for an electric railway to extend from Bessemer to Blue Creek, Brookwood and Blockton. The move is at present purely a local one, with the end in view of including outsiders to lend aid if a favorable report is made on the project. S. E. Jones and W. J. Parkes are members of the committee which has the matter in charge.

SAN JOSE, CAL.—Articles incorporating the Santa Clara Valley Transit Company have been filed. The capital stock is placed at $1,000,000, of which $25,000 has been subscribed. The directors are: F. M. Lockwood, J. A. Mehling, V. A. Scheller, W. C. Andrews and A. D. Cutler.

PUEBLO, COL.—Leading citizens of Bessemer are the promoters of a plan to establish an electric railway here.

STONINGTON, CONN.—The Westerly Railway & Lighting Company, of Stonington, has filed a certificate of organization. The authorized capital stock is $400,000. The company will begin business with $20,000 capital. It is organized to construct and operate railroads, street railways, electric light plants, power plants, gas works and ferries. The directors are: James O. Sweet, Jewett City, Conn.; Francello G. Jilson and Frank P. Sheldon, of Providence; Nathan B. Lewis, of West Kingston, R. I.; Joseph M. Kingelsmith, of Stonington, and H. Hobart Babcock, George W. Mansfield and William Hoxsey, of Westerly. Subsequently, the directors elected Frank P. Sheldon president; George W. Mansfield, vice-president; Nathan B. Lewis, secretary, and Joseph M. Kingelsmith, treasurer.

WATERBURY, CONN.—The local municipal authorities have granted to the Cheshire Street Railway Company the necessary rights to construct the Waterbury end of the proposed line between this city and Cheshire. The Cheshire Company is an underlying corporation of the Connecticut Railway & Lighting Company.

HILLSBORO, ILL.—The Hillsboro Electric Railroad Company has been organized, with a capital stock of $15,000. The incorporators are: Isaac Hill, T. M. Jett and L. V. Hill.

EAST CHICAGO, IND.—The Hammond, Whiting & East Chicago Electric Railway Company has increased its capital stock from $300,000 to $1,000,000.

ANDERSON, IND.—The Indiana Union Traction Company will begin the construction of its new shops here this summer. The company has set aside $150,000 for this work.

CRAWFORDSVILLE, IND.—It is anounced that the Consolidated Traction Company will, in a few days, receive bids for the construction of a large power house in this city. Edward Hawkins is president of the company.

RICHMOND, IND.—The Richmond & Northwestern Electric Railway Company has been incorporated. The capital is $50,000, and the directors are: George M. Hodges, G. G. Bambach, W. D. Riddel and L. I. Lowman, of Dayton.

EVANSVILLE, IND.—The Evansville, Boonville & Rockport Traction Company has completed its survey to Rockport, a distance of 37 miles, and has contracted for private right of way from Evansville to Boonville, a distance of 17 miles.

INDIANAPOLIS, IND.—The Jackson & Fort Wayne Interurban Railway Company has filed articles of incorporation with the Secretary of State. The object of the corporation is to construct and operate an electric railway from Indianapolis to Jackson, Mich. The line will be 130 miles long. The capital stock of the company in Indiana is $50,000. The incorporators and stockholders are: John H. Roberts, Joseph McKee, Charles W. Wadkins, of Grand Rapids; Will H. Mann, of Muskegon; William Sullivan, of Mackinac Island, Mich.; Stephen H. Powers, of Angolia, Ind.

MARSHALLTOWN, IA.—It is reported that a contract has been closed with J. G. White & Company, of New York, for the construction of the Marshalltown Electric Street & Interurban Railway. The road will be built from Marshalltown to Grundy Center, 30 miles, and then, if feasible, will be extended to Parkersburg and ultimately to Charles City, on the north, and to Ferguson, south of Marshalltown. The power house will be built at Marshalltown.

LOUISVILLE, KY.—The Louisville & Southern Indiana Traction Company has been granted a franchise to enter the city.

PADUCAH, KY.—Articles of incorporation for the Kentucky & Ohio River Interurban Railroad Company have been filed here. The company is capitalized at $250,000, and the incorporators are: J. J. Freundlich, C. E. Whitesides, O. B. Williams, of Paducah; O. B. Pettit, of Wabash, Ind.; L. B. Whitesides, of Franklin, Ind., and C. T. Crump, of Columbus, Ind.

LAKE CHARLES, LA.—W. C. Easterling and W. C. Pfeiffer have applied to the City Council of this town for a franchise for constructing and operating an electric street railway system here. They represent a syndicate of Pennsylvania capitalists.

ANNAPOLIS, MD.—A bill will be introduced in the Legislature to grant a charter to the Baltimore, Westminster & Union Mills Railway Company. The incorporators of the company named are Charles E. Fink, Joseph Friedenwald, W. A. Jackson and others. The capital stock is to be $20,000.

ANNAPOLIS, MD.—A bill has been introduced in the Senate to incorporate the Roland Park Electric & Water Company. The capital stock is $25,000, and the company is to operate in Baltimore city. The incorporators are Edward H. Bouton, George Miller, Robert J. W. Hamill, Richard W. Marchant, Jr., and Osborn I. Yellott.

BOSTON, MASS.—The Nahant Selectmen have granted the franchise for the new electric railway between that town and Lynn to the Nahant Street Railway Company, which includes among its incorporators Senator Henry Cabot Lodge, George Abbot James and others. Frand Ridlon & Company will finance the road and supervise its construction.

WORCESTER, MASS.—Representatives of the Worcester & Northern Street Railway Company have been at work, so it announced in Worcester, buying up stock of the Gardner, Westminster & Fitchburg Street Railway, which operates a line to the base of Mt. Wachusett. The Worcester & Northern proposes to run a line to the top of the mountain, using a cable road, and wants the line from Gardner and Fitchburg as a feeder.

ATTLEBORO, MASS.—Preliminary plans for a new street railway to connect the Milford, Attleboro & Woonsocket Street Railway with the Boston & Worcester road are well under way, and the legal papers have been drawn up and submitted to Boston capitalists, who will finance the new company. The company proposes to purchase the Caryville branch line from the Milford, Attleboro & Woonsocket Company.

WORCESTER, MASS.—It is announced that a company to be known as the Worcester, Southbridge & Sturbridge Street Railway Company is about to be formed, to acquire the Worcester & Southbridge Street Railway after that road has passed out of the hands of the receivers, and to acquire also the Southbridge & Sturbridge Street Railway, which has been operated under the Worcester & Southbridge management. The company is said to have a capital stock of $700,000. It is said that William E. Rice, who has been prominent in the settlement of the troubles of the Worcester & Southbridge Company, will be president of the new corporation. The two roads will be put up for sale at auction as soon as the claims have been adjusted, and it is the purpose of the new company to bid them in.

MONROE, MICH.—The Detroit, Monroe & Toledo Short Line is making extensive improvements at its power house in order to provide better facilities for handling the new extension to Detroit, which is now nearing completion. A new engine, generator and additional boilers are being installed.

GRAND RAPIDS, MICH.—The Grand Rapids, Holland & Lake Michigan Interurban Railway Company has elected members of the board of directors for the ensuing year. Directors organized as follows: Benjamin S. Hanchett, president; John P. Crozier, vice-president; Willard Kingsley, secretary; Strathearn Hendrie, treasurer and general manager.

MINNEAPOLIS, MINN.—The Twin City Rapid Transit Company proposes to extend its present White Bear line from Mahtomedi to White Bear village, passing through Dellwood and White Bear Beach.

LEXINGTON, MO.—The citizens of Lexington are considering the proposition of building an electric railway from Nigginsville to Lexington Junction. Gustave Maerie is the promoter.

KANSAS CITY, MO.—A sub-station is to be built at Twelfth Street and Cleveland Avenue by the Metropolitan Street Railway Company. Two rotaries will be installed, and from them power will be supplied to the car lines on the East Side. When the new station is in commission the stations at Eighth Street and Woodland Avenue and Eighteenth and Olive Streets will be shut down. The sub-station at Fifteenth and Walnut Streets will also be equipped with two rotaries. One will be transferred from the Kaw River power plant, the other is now on the way from the east. The equipment at the power station at Thirty-first and Holmes Streets will also be improved. Two engines at the new plant at Second Street and Grand Avenue are now in commission, and a third engine will be ready for service by June 1.

NEWARK, N. J.—President Thomas N. McCarter, of the Public Service Corporation, has made formal application to the Board of Public Works of Newark for permission to construct five extensions to the trolley system.

SUMMIT, N. J.—An agreement has been reached between the Springfield Township Committee and the Morris County Traction Company, whereby the company will be given a franchise through the township for its proposed electric railway from Summit to Elizabeth.

BATH, N. Y.—The Bath Town Board has granted a franchise to John Tuerk to construct the proposed electric railway from Branchport to Hornellsville.

LOCKPORT, N. Y.—It is announced that all the finances have been arranged for the completion this summer of the electric railway between Lock port and Rochester, via Albion.

ROCHESTER, N. Y.—The entire proceeds of the $100,000 of new stock recently authorized to be issued by the stockholders of the Rochester Railway Company will be used for improvements.

EAST AURORA, N. Y.—The Buffalo & Southeastern Electric Company has been granted a franchise to operate an electric railway here. John H. Boyle, of Utica, is promoting the company. The plan is to connect with Buffalo.

GREENSBORO, N. C.—The Greensboro Electric Company has decided to make many improvements to its system. It is said that a new steam turbine wheel will be installed at the power house. The boiler capacity of the plant will be increased and improvements will be made in the rolling stock.

TOLEDO, OHIO.—Stockholders of the Toledo & Indiana Railway Company will meet April 5 to discuss plans for extending the road westward and for the erection of a large power house.

CLEVELAND, OHIO.—The Eastern Ohio Traction Company will build a new line from Euclid Heights to Warrensville, which will provide a new route into the city for the cars of the Garrettsville division of the road.

COLUMBUS, OHIO.—The Marion, Bucyrus & Tiffin Railway & Light Company has been incorporated, with $10,000 capital stock, by M. B. Earnhart, J. B. DeWitt, S. S. Thorn, O. M. Blake and W. H. Davidson. The company proposes to build an interurban line between Marion, Bucyrus and Tiffin. This is one of the most important projected lines in Ohio, as its completion will make possible, through electric travel between Cincinnati and Toledo and Cincinnati and Cleveland. The Municipal Bonding & Securities Company, of New York, is financing the road.

GUTHRIE, O. T.—A territorial charter has been granted to the Oklahoma City, Lexington & Sulphur Springs Electric Railway Company, with headquarters at Lexington, with $1,000,000 capital. The incorporators are: Charles Stewart, of Parkersburg, W. Va.; H. A. Hawk, J. S. Little, H. L. Forehead and others.

FRANKLIN, PA.—Application has been made to the State Department at Harrisburg for a charter for a company to construct an electric railway from Franklin to Butler, a distance of 53 miles. The company is to be capitalized at $400,000.

ALLIANCE, PA.—An ordinance has been introduced in Council granting a franchise to the Blue Ridge Electric Passenger Railway Company. The line will run from Walnutport, along the Lehigh River, to Alliance, crossing over to Bath and Nazareth.

WILKINSBURG, PA.—A charter has been issued by the State Department to the Wilkinsburg & Braddock Electric Street Railway Company to construct a line from Turtle Creek to Wilkinsburg. The capital is $21,000. Hawley McKinney, of Pittsburg, is president.

PROVIDENCE, R. I.—The act authorizing the Pascoag & Providence Street Railroad Company to increase its capital stock to $300,000 has been passed by the Senate in concurrence with the House of Representatives.

CHATTANOOGA, TENN.—The stockholders of the Chattanooga Electric Railway Company have decided to build a line to Chickamauga Park.

OGDEN, UTAH.—The City Council has granted a franchise to the Ogden Rapid Transit Company to extend its system into the suburbs of the city. The equipment required will be ordered at an early date.

ST. ALBANS, VT.—The St. Albans Street Railway has suspended operations, and rumor has it that the company is financially embarrassed.

RICHMOND, VA.—It is stated that the Richmond Passenger & Power Company has under consideration the extension of its lines to Washington by way of Ashland and Fredericksburg.

COLFAX, WASH.—The Board of County Commissioners has granted a franchise to the Palouse & Spokane Electric Railway Company for an electric railway from Spokane to Colfax.

HAMILTON, ONT.—The Hamilton, Grimsby & Beamsville Electric Railway Company will make additions and improvements to its plant.

WOODSTOCK, ONT.—Wallace & Little, of this city, will apply for a charter for an electric railway between Crantford and Hamilton. David Brennan, of Detroit, and other American capitalists are interested.

New Industrial Companies.

THE EASTERN ELECTRIC COMPANY, of Newport News, Va., has been chartered, with A. L. Powell president.

THE MICHIGAN AUXILIARY FIRE ALARM COMPANY has been incorporated at East Orange, N. J.; capital, $30,000. Incorporators: Paul Muntur, Joseph Genwardt and Charles A. Green.

THE GUSTAVE S. NEU COMPANY of New York has been incorporated to deal in electrical supplies. The capital stock is $10,000, and the directors are G. S. Neu, Marion Neu and W. L. Frank, New York.

THE SHEDD ELECTRIC COMPANY, of Elizabeth, N. J., has been incorporated; capital, $250,000. Incorporators: William H. Peck, J. Foster Symes, C. A. Matthews, H. C. Henshaw and H. Richmond Palmer.

THE FIELD MULTIPLEX TELEGRAPH INSULATION COMPANY has been incorporated at Jersey City, N. J., with a capital stock of $20,000. The incorporators are James D. Campbell, R. W. Ashcroft and Kenneth K. McLaren.

THE INTERNATIONAL ACCUMULATOR COMPANY has been incorporated at Portland, Me., with a capital stock of $1,000,000, of which $50 has been put in. The officers are: President, Ardon W. Coombs, Portland; treasurer, Winfield S. Carpenter, Boston.

Legal.

NEW ORLEANS FRANCHISES.—At New Orleans, on March 26, Attorney-General Guion brought suit in the District Court to have the New Orleans Railways Company, a company chartered under the laws of New Jersey, declared unconstitutionally incorporated, and therefore unable to do business in Louisiana. The company has a capital of $80,000,000, most of the bonds being held in New York. It controls all the street car and suburban lines of New Orleans, besides owning the gas works and electric light plant of the city and furnishing all light—gas and electricity—for public and private lighting.

Obituary.

MR. H. H. CARPENTER.—Mr. Hiram H. Carpenter, an inventor of electrical devices, died on March 28 at Bellevue Hospital, New York City. He had recently returned from a European tour. He was born in Williamstown, Mass., sixty-four years ago, and was a cousin of the late United States Senator Matthew Carpenter of Wisconsin. He invented and improved some storage batteries, and lately had been engaged upon a wireless telephone. He was an officer in the Iron Brigade of Wisconsin in the Civil War, and commanded the Twentieth New York Cavalry during the latter part of the war.

MR. C. D. CRANDALL.—It is with deep regret that we note that Mr. Chester D. Crandall, manager of the Western Electric Company, died at his home in Edgewater, Chicago, March 22, 1904. He had been a prominent figure in the Bell telephone field for many years. Soon after he graduated from the University of Rochester in 1879, he became connected with the Western Electric Company. At one time he was associated with the Missouri & Kansas Telephone Company at Kansas City, but returned to the Western Electric Company. He was a member of the Union League Club and other prominent clubs in Chicago. He had been an associate member of the American Institute of Electrical Engineers for several years. He leaves a wife and daughter.

PERSONAL.

ASA M. MATTICE.

MR ASA M. MATTICE has accepted the appointment of chief engineer of the Allis-Chalmers Company. Mr. Mattice was graduated from United States Naval Academy, Annapolis, Md., at the head of the class of Cadet Engineers of 1874, and remained in the naval service until 1889. During his 17 years' service, he was attached to the Naval Academy for three years as instructor in engineering, and acted three years as assistant to the Engineer-in-Chief of the Navy at Washington, D. C. The remainder of his duty was on board ship and at navy yards. While serving as assistant to the Engineer-in-Chief, he had direct charge of the designs for the machinery of the first vessels of the new navy, and the great success of the several new types originated led to their rapid adoption in the navies of the world. From the time of Mr. Mattice's resignation from the Navy until the end of 1899, he was the principal assistant to Mr. E. D. Leavitt, consulting engineer, Cambridgeport, Mass., where his work was principally in connection with large mining machinery, pumping engines, mill plants and power plants, along with a great deal of miscellaneous engineering. In 1900 he resigned to engage in independent engineering, but in December of that year accepted an appointment as chief engineer of the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa. In June, 1903, he was appointed chief engineer of the Westinghouse Machine Company, East Pittsburgh, Pa., and consulting engineer of the Westinghouse Electric & Manufacturing Company, which positions he held up to the present date. Mr. Mattice took up his new duties on April 1 with headquarters at the central works of the Allis-Chalmers Company, Milwaukee.

F. H. BETHELL.

MR. FRANK HOPKINS BETHELL has been appointed general manager of the Chesapeake & Potomac Telephone Company, with headquarters at Washington, D. C. He is one of the youngest managers in the present Bell telephone system to hold so prominent and responsible a position. Mr. Bethell began his telephonic career in that excellent school, the New York & New Jersey Telephone Company, and was connected with its Brooklyn office. He went thence to the New York Telephone Company, and for the past three years has been its contract agent. His work in this arduous position has been of a really brilliant character and has attracted considerable notice. During the three years of his incumbency the company has doubled the number of telephones in use in Manhattan and the Bronx, so that at the time this is written there are not less than 140,000 telephone stations installed or under contract in the district named, this being by far the largest telephonic network in the world. Mr. Bethell's success in New York has been due to his own efforts. He has a clever diplomatic way of handling men, and the high *esprit de corps* in the contract department is due to his methods, while at the same time he has made friends with the great New York public, so that complaints are rarely heard. Mr. Bethell has developed business in many ways, and is a great believer in advertising. His work in the New York newspapers, as well as in the booklets he has constantly sent out, has been attended with the splendid results as noted above. Great regret is felt by the officers of the New York Telephone Company as well as by Mr. Bethell's own immediate staff at his departure, but they realize that the move is strictly in the line of promotion and wish him abundant success. He begins his new labors on April 1. The principal points covered by the Chesapeake & Potomac Company are Washington, Baltimore, Annapolis, Belair, Cumberland, Frederick, Hagerstown, Westminster, Md., and Martinsburg, W. Va. Comprising as it does the national capital, this field involves at once great opportunities and great responsibilities, while at the present time the work is complicated by the heavy restorations necessary in Baltimore after the great fire.

MR. H. W. POTTER, of the export department of the Westinghouse interests, sailed March 29 for Panama. He expects to be absent about a month.

MR. B. E. SALISBURY, secretary and general manager of Pass & Seymour, Inc., of Solvay, N. Y., was in New York City last week on important business for that concern.

MR. CLINTON L. ROSSITER, president of Rossiter, MacGovern & Co., has gone to Mexico in connection with the Toluca Light & Power Company, in which he is interested.

MAJOR W. A. GLASSFORD, U. S. Signal Corps, upon his return to this country from service abroad shortly, will proceed to Atlanta, Ga., and report for duty there as signal officer.

MR. FRANCK Z. MAGUIRE, of London, has just arrived in this country by the "St. Louis," and will be here for two or three weeks, going first to Washington.

MR. S. B. FORTENBAUGH, electrical engineer of the Underground Electric Railways Company of London (Yerkes syndicate), is now in this country on a flying trip, and has been visiting Schenectady, etc.

MR. JOHN McDOUGALL, of Montreal, Can., who represents the interests of the International Steam Pump Company, 114 Liberty Street, in that part of the world, is now on a visit to New York.

MR. A. M. BARRON has moved from Indianapolis, Ind., to South Bend, Ind., where he will continue his engineering work. Mr. Barron is secretary of the Indiana Public Utilities Association, which will hold its next meeting at Indianapolis in October.

PRESIDENT CHARLES SUMNER HOWE is to be installed as head of the Case School of Applied Science, Cleveland, Ohio, on May 11. Considerable preparations are now being made for the inauguration exercises, and official invitations are being sent out.

MR. G. W. FRANK, of J. G. White & Co., 49 Exchange Place, New York, has gone to Mexico for the purpose of supervising the remodeling of the Monterey Electric Light & Power Company's plant, the contract for which is being carried out by J. G. White & Co.

MR. W. K. PALMER, consulting engineer, 402 Lyceum Building, Kansas City, Mo., is engineer for the municipal lighting plant for Versailles, Mo. Plans and specifications will be ready in about two weeks. Bids will be required on boilers, engines, generators, switchboard, poles, etc., together with the building.

MR. MARTIN MOLONEY.—A cable dispatch from Rome of March 26 says: "Marquis Martin Maloney, of Philadelphia, and Miss Maloney were to-day received in private audience by the Pope, who conversed with them at considerable length in the most cordial manner. They were presented to His Holiness by Cardinal Satolli."

MR. LOUIS F. MAHLER, formerly western manager of the De Laval Steam Turbine Company, and St. Louis manager for the Bullock Electric Manufacturing Company, is now representing the Buckeye Engine Company, of Salem, O.; the International Steam Engineering Company, of Atlanta, Ga., and New York, and the Chase-Shawmut Company, of Newburyport, Mass., at Suite 1008-9 Chemical Building, St. Louis.

DR. A. C. CREHORE, of Yonkers, N. Y., has issued in neat pamphlet form a recent article of his in *Country Life in America*, describing a new sun-dial that tells standard time all the time the sun shines and indicates the time of sunrise and sunset throughout the year. The gnomon of an ordinary dial is represented in this form by a phosphor bronze wire carrying a small metal head.

MR. F. W. BENNETT, chief engineer of the Cienfuegos, Palmira & Cruces Electric Power & Railway Company, is expected to arrive from Cuba very shortly. The company is to build a large hydraulic plant for the purpose of generating power for light and traction use in the Santa Clara province. The consulting expert of the company is Mr. Cornelius C. Vermeule, 203 Broadway, New York.

MR. EDWARD BENNETT has resigned from the Nernst Lamp Company and with Mr. Murray C. Beebe will engage in engineering and expert work with offices in the Farmers' Bank Building, Pittsburg. Mr. Bennett became associated with the development of the Nernst lamp shortly after the inception of the work in this country, and for the past fifteen months has served as chief electrician of the Nernst Lamp Company.

MR. HUGH L. COOPER, at one time hydraulic engineer of the Stilwell-Bierce & Smith-Vaile Company, and who later on acted as expert in charge of the large water power plant on the Rio Tiete, Brazil, operated by the Sao Paulo Tramway, Light & Power Company, is now in charge of the construction of the Mexican Light & Power Company's extensive system. He has sailed for Mexico after a short visit to the States.

MR. EDWARD GUINLE, of the electrical engineering and contracting firm of Aschoff & Guinle, of Rio Janeiro, Brazil, will arrive very shortly on a somewhat extended visit to the United States. The firm represent the Brazilian interests of several large American electrical and mechanical concerns. Mr. Guinle will make his headquarters in the offices of G. Amsinck & Co., 6-9 Hanover Street. He is expected to place some large contracts.

MR. S. M. CONANT, now representing the Crocker-Wheeler Company of Ampere, N. J., in Atlanta, Ga., is to be married at Holy Trinity Church, Church Road, Richmond, Va., Tuesday, April 5, to Miss Helen Temple Southall, daughter of John H. Southall, treasurer of the Virginia Trust Company of Richmond. The ceremony will be performed by the Rev. C. M. Conant, M. D., father of the bridegroom, assisted by the Rev. Dr. Gravatt, rector of Holy Trinity.

MR. F. S. PEARSON, 29 Broadway, New York, has gone on a trip to Mexico for the purpose of inspecting the progress made in the construction of the Mexican Light & Power Company's Mecaxa plant, which is to generate initially no less than 45,000 hp for transmission to Mexico City, etc. Mr. Pearson is vice-president and consulting engineer of the company, which is controlled by Canadian capitalists. He expects to be back in about ten days.

MR. JAMES MITCHELL, general manager at Sao Paulo, Brazil, of the Sao Paulo Tramway, Light & Power Company, is expected to arrive in New York next week. Mr. Mitchell was formerly one of the partners of the recently dissolved firm of James Mitchell & Co., of Rio de Janeiro and Sao Paulo, which represented the interests of some of the leading United States electrical concerns. While in New York he will make his headquarters in the Sao Paulo Company's office, 29 Broadway.

MR. MURRAY C. BEEBE has resigned from the Nernst Lamp Company, and in association with Mr. Edward Bennett, has opened an office in the Farmers' Bank Building, Pittsburg, to engage in the practice of electrical and mechanical engineering and in expert work. Mr. Beebe was for several years an instructor in electrical engineering in the University of Wisconsin, which position he left to take up work on the development of the Nernst lamp, and when the Nernst Lamp Company was later formed, became its chemist and technical superintendent.

MR. GEORGE J. GOULD on his recent trip through the Southwest was so pleased, it is said, with the performance of the engine which drew his train over 5000 miles without a break that he presented the engineer and fireman who handled it with purses each containing $100 in gold. The locomotive plowed its way through snow, ran through the heart of the Salt River Valley, was fed with forty different kinds of coal, and used water of every known analysis in its boiler, yet the only repairs it needed were such as were made en route by the crew. His Manhattan Elevated electric locomotives have also been doing about as well.

MR. W. MARCONI has had the misfortune to lose his father, Mr. Giuseppe Marconi, at the age of 82, at Bologna, Italy. Mr. Giuseppe Marconi was born in 1823. The mother of William Marconi, of wireless telegraph fame, was his second wife. She was Miss Anna Jameson, daughter of the founder of the well-known Dublin firm. She was a beautiful girl and was sent to Italy to complete her education. She met in that country the elder Marconi, a dashing young Italian, who was of good family, in possession of a large estate near Bologna, their mutual liking arising out of a common taste for outdoor sports. Their elder son, Alfonso, was born in 1865 and William in 1874, at the family house, the Villa Grifone, near Pontecchio. Signor Marconi took great pride in his son's achievements.

MR. FRANK W. FRUEAUFF, auditor of the Denver Gas & Electric Company, has been asked by President Edgar to report on office methods and accounting at the 27th convention of the National Electric Light Association, to be held in Boston May 24-27. Mr. Frueauff is a very progressive young man, and as he is familiar with the up-to-date methods of keeping central-station accounts, including modern devices for saving time and insuring accuracy in office work, the report, which he has promised to prepare, is sure to be a valuable addition to the programme of the meeting.

PROF. F. G. BAUM, formerly assistant professor in the department of electrical engineering at Stanford University, California, has been appointed electrical engineer and general superintendent of the California Gas & Electric Corporation, which recently absorbed the Standard Electric Company and now controls all the local distributing companies around the bay. Prof. Baum will have entire charge of all construction and operation of the water systems, power houses, transmission lines and sub-stations of the company. Prof. Baum graduated from Stanford in 1898, taking the degree of electrical engineer a year later. He then became connected with the department as instructor and assistant professor. He resigned a year ago on his appointment as assistant electrical engineer of the corporation of which he becomes chief engineer and general superintendent.

MR. ANDREW CARNEGIE.—The reason for Mr. Andrew Carnegie's gift of $50,000 to Kenyon College, at Gambier, Ohio, announced just as he sailed for Scotland, is that it is an expression of Mr. Carnegie's grateful remembrance of kindness shown to him years ago by Edwin M. Stanton, who, when secretary of war in President Lincoln's cabinet, made Mr. Carnegie assistant manager of posts and telegraphs. Mr. Carnegie's gift will be used to establish what is to be known as the Edwin M. Stanton chair of economics. Mr. Carnegie gave the money on learning that Mr. Stanton's early education had been secured at Kenyon College. The gift was partly due also to a suggestion from the late Senator Hanna, who had himself given $50,000 to the college to found a dormitory. Mr. Carnegie has always welcomed such opportunities to emphasize his various close relationships with the telegraphic field.

MR. WINSLOW H. HERSCHEL, who has been stationed at the Jerome Park Reservoir, Aqueduct Department of New York City, has sailed for Europe on behalf of the Allis-Chalmers Company. He will remain on the other side for a year, making his headquarters at Zurich, where he will act as local agent and technical correspondent for the company. The works of Escher, Wyss & Co. are located at Zurich. As previously mentioned in these columns, the Allis-Chalmers Company has acquired the American rights for the Swiss concern's water turbines. Mr. Clemens Herschel, M. Am. Soc. C. E., formerly hydraulic engineer of the Holyoke, Mass., Water Power Company, also consulting hydraulic engineer from time to time during the past score of years for several Niagara water power companies, has charge of the new water turbine and other hydraulic machinery department of the Allis-Chalmers Company.

MESSRS. KEMPSTER B. MILLER AND S. G. McMEEN, two of the best known telephone engineers of Chicago, have become associated as consulting engineers, experts and solicitors in patent causes, and will open offices at 1442 and 1443 Monadnock Block, Chicago, about May 1, 1904. As consulting engineers in the telephone field they will fill a place hitherto unoccupied even in such an important independent telephone center as Chicago. Mr. Miller needs no introduction as a telephone engineer. He is a graduate of Cornell. After several years in the U. S. Patent Office as examiner of telephone patents he left to become one of the pioneer independent telephone manufacturing company engineers with the Western Telephone Construction Company of Chicago. He left that company to accept a much higher salary as instructor in telephony for the International Correspondence Schools, where he remained a year. About four years ago when the Kellogg Switchboard and Supply Company was started he took an important engineering position with that company which he has held ever since. His book on "American Telephone Practice" is recognized as the standard work on telephone circuits and switching, being the only comprehensive book of the kind in the field. Mr. S. G. McMeen is best known through his long connection with the Central Union Telephone Company as chief engineer and assistant engineer. Graduating from Purdue in 1895, he went at once into field work for the Central Union Telephone Company. In 1893 he became assistant chief engineer, and later chief engineer, until 1902, when he took charge of the telephone central office and exchange equipment work for the Western Electric Company, where he has been for the two years just past. It would be hard to find two engineers better fitted by all around experience and personal acquaintance to enter the telephone consulting field than Messrs. McMeen and Miller, and the industry is to be congratulated on having available such talent outside of the manufacturing companies. It is a good thing for the business.

Trade Notes.

OIL FILTERS.—The American Ship Building Company has given a second order for Cross oil filters for its yards at Lorain, Ohio.

THE BOSSERT ELECTRICAL CONSTRUCTION COMPANY, of Utica, N. Y., has increased its capital stock from $75,000 to $100,000.

THE BUFFALO STRIKE.—The strike of electrical workers at Buffalo, N. Y., has been settled by a complete backdown of Local Union I. B. E. W., in regard to all the vital points at stake.

AUTOMOBILE MOTORS.—The Elwell-Parker Electric Company, Cleveland, O., has recently closed a contract for a large number of automobile motors, and the company is building a number of 200-hp heavy-duty hoisting motors.

SALUS COMPOUND.—The Electric Appliance Company, Chicago, is anxious to tell the world about "Salus Compound," which is the insulation that it claims makes the Packard transformer so effective. It has literature on the subject and will be glad to send it to any address.

MILLING MACHINES.—The Hess Machine Company, Fifteenth and Chestnut Streets, Philadelphia, in a pamphlet just issued describes and illustrates its line of milling machines and cutters for large output. The company furnishes electric motor drive, designed to suit each individual case, and the company has on hand designs suited for direct, alternating and multivolt motors, low and high speed.

DINKEY VENTILATED CONTROLLERS.—A very handsome and complete illustrated catalogue has been issued by the manufacturers of the Dinkey ventilated controllers, the Electric Controller & Supply Company, of Cleveland, O. The construction is shown complete and in detail of this apparatus for cranes, the original type of which was brought out at the Homestead Steel Works of the Carnegie Steel Company to meet the special requirements of steel works. The catalogue is known as Bulletin No. 9.

HAND PORTABLE ELECTRIC DRILLS.—E. H. Cadiot & Company, 12, Rue St. Georges, Paris, France, have made hand portable electric drills a specialty since 1896. They have sent us a new catalogue of these machines, whose object is to enable small drill holes to be made in any kind of material or machinery which cannot be easily transported to large electric drilling machines. These small drills have met a steady and increasing sale. Messrs. Cadiot have recently introduced some powerful machines of this class, which, however, retain all their portable features and are in every way up to date.

THE NERNST LAMP COMPANY has recently established district offices at St. Louis, Mo., and Denver, Col. The St. Louis office, embracing the southwest territory, is located at 908 Pine Street, with Mr. H. M. Reed as district sales manager. The Denver office, covering the middle western territory, is at 1619 Glenarm Street, with Mr. F. D. Marthens as district sales manager. These offices will carry a complete stock of Nernst lamps and supplies, and will be provided with an attractive exhibition room, in which will be shown the different types of Nernst lamps in actual operation and in comparative tests with other illuminants.

REMODELING OF POWER PLANT.—The Canadian Rubber Company of Montreal recently remodeled its power plant and found that the tall brick chimney, 110 feet high, would not give the proper amount of draft necessary in connection with the four new Stirling boilers it was to install. Mechanical draft was necessary, and for this purpose a large Sturtevant horizontal engine was installed, and now the proper amount of draft is easily attained and regulated at will regardless of the weather conditions. This installation is another illustration of the necessity of mechanical draft, especially in connection with the remodelling of old boiler plants.

HOW TO MAKE INDICATORS, reducing wheels and planimeters and how to use them intelligently from the first lesson to the last, is a line of instruction which any progressive engineer should be interested in. Such a course is being offered by the Indicator Instruction Company, No. 19 Franklin Avenue, Scranton, Pa. This is a concise, practical course of instruction, as it covers the subject in twenty-four pages from the making of the patterns to the construction and testing of an indicator spring. The company is making a special offer for enrollments received prior to April 15 and offers to send prospectus and all particulars free to those interested. Mr. A. C. Lippincott is the instructor.

THE NATIONAL-ACME MANUFACTURING COMPANY, Cleveland, O., manufacturer of the Acme automatic multiple spindle screw machine and parts produced on this machine, has recently found it necessary to add a night shift in its products department. The speed and accuracy of its Acme machine enables it to rapidly produce special milled work from steel, iron and brass, and the company has been particularly successful in securing business of this class from telephone, battery and electrical instrument manufacturers. Its business in the machine tool line is fully up to that of last year. An interesting machine recently shipped by this company was a multiple spindle screw machine for producing caulks for cavalry horses for the Japanese army—an instance of the careful attention which the "Yankees of the East" are giving to the most minute details in the care of their army equipment.

THE ROSSITER, MACGOVERN Electrical Company, western agents of Rossiter, MacGovern & Co., has found it necessary, owing to the very large increase in its office staff, to move its offices from the Missouri Trust Building to its factory, corner Papin Street and Compton Avenue, St. Louis. The business under the active management of Mr. J. A. Peirce has increased immensely since the company was first organized, less than two years ago. Among recent contracts taken by this company is the complete installation of the power house of the Kokomo, Marion & Western Traction Company, Kokomo, Ind., calling for the complete installation of a power station of 1000 kilowatts. Everything is furnished, including engines, boilers, generators, pumps, etc., and two 150-kw motor-generator sets. The company is also installing one 500-kw direct-connected, direct-current 600-volt unit in the station of the Louisville Lighting Company, Louisville, Ky., besides having in hand a large number of the electrical exhibit installations at the Louisiana Purchase Exposition.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED MARCH 22, 1904.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., New York.]

754,969. STORAGE BATTERY; Martin C. Burt, Chicago, Ill. App. filed Aug. 13, 1903. (See page 658.)

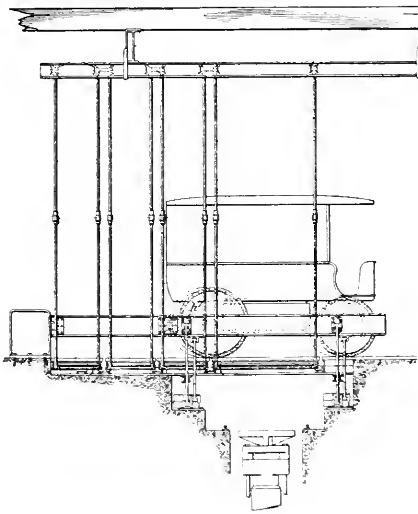
754,980. SYSTEM OF SPEED REGULATION FOR MOTOR-DRIVEN MACHINERY; Gano S. Dunn, East Orange, N. J. App. filed Aug. 20, 1903. A variable speed motor is combined with a number of trains of gears, the velocity ratio of the gear trains being proportioned so that the entire range of speed obtained with each successive train covers a portion of the range obtainable with the next succeeding train.

754,997. METHOD OF PROVIDING CABLES OR OTHER FLEXIBLE BODIES WITH SOLID ENDS; George G. M. Hardingham, London, England. App. filed Mar. 21, 1903. The cable is inserted in an opening in the head and a tool driven into another opening to force the metal into intimate contact with the cable.

755,029. ARMATURE WINDING OR COIL; Frank A. Merrick, Johnstown, Pa. App. filed Nov. 9, 1899. A form of coil intended to occupy small space at the heads of the armature.

755,032. APPARATUS FOR WIRELESS TRANSMISSION OF ENERGY; Daniel M. Moore, Newark, N. J. App. filed Apr. 18, 1903. The current is broken in a vacuum, the object being to create the waves or vibrations of radiant energy in a more economical and effective manner.

755,048. AUTOMATIC CIRCUIT CLOSER; James L. Russell, Boston, Mass. App. filed Nov. 2, 1903. A tubular walking-beam containing an expansible liquid is arranged near two lamps and controls the circuit of the lamps by oscillating from one position to the other by reason of the heating effect of the lamp upon the liquid contents of the beam.



755,087.—Positioning Apparatus for Vehicles.

755,087. POSITIONING APPARATUS FOR VEHICLES; George A. Ward, New York, N. Y. App. filed Dec. 23, 1902. The sections of a platform upon which the vehicle runs to receive its battery are movable by power devices so as to position the vehicle accurately with respect to the platform upon which the battery is deposited.

755,092. LINE WIRE CLAMP; Herman C. Willitz, Janesville, Wis. App. filed Oct. 17, 1903. A U-shaped spring plate adapted to clamp the wire and a link embracing and confining the ends of the clamp.

755,121. ELECTRICAL APPARATUS FOR THERAPEUTIC PURPOSES; Frederick C. Fisher, Bristol, Eng. App. filed Sept. 21, 1903. Details.

755,125. ALARM DEVICE; William Friedberg, New York, N. Y. App. filed Nov. 11, 1903. Details of a door knob circuit closer.

755,140. ELECTRIC RAILWAY SIGNAL; Bertram M. Kershner, Pittsburg, Pa. App. filed June 21, 1902. A signal wire extends over a block and is normally grounded at each end; the car automatically disconnects one end from the ground and connects it to a source of current supply to actuate the signal.

755,141. ELECTRICAL SWITCH MECHANISM; Hubert Krantz, Brooklyn, N. Y. App. filed June 29, 1903. A special arrangement of the cross-bars and bus-bars of a switchboard affording a saving in material in the construction.

755,142. STORAGE-BATTERY CONSTRUCTION; Simon Lake, Bridgeport, Conn. App. filed Dec. 17, 1903. (See page 658.)

755,165. ELECTRIC SWITCH; Ashley P. Peck, Milwaukee, Wis. App. filed Sept. 21, 1903. A switch having insulating barriers so arranged that when the ends of the movable contact leave the stationary contacts, they are practically inclosed in insulating material.

755,173. ELECTROPNEUMATIC SYSTEM OF DRIVING; Johann Sahulka, Vienna, Austria. App. filed Apr. 18, 1903. A compressor driven from the motor shaft charges an air tank, which supplies an air engine also connected to the axle. The electric motor acts as the main working motor, the air engine being used in starting going over sections of the track where there are no line conductors and in cases where an extra amount of power is required. A controlling device common to both motors enables one or the other motor to be thrown in or out.

755,203. ELECTROMAGNETIC RAIL BRAKE; Karl A. Wilde, Hamburg, Germany. App. filed Dec. 1, 1903. A plurality of pole pieces carrying brake shoes and having tubular extensions, detachably connected together for convenience in assembling and replacing the parts.

755,229. COIL FOR ELECTROMAGNETS OR OTHER PURPOSES; Friedrich Klingelfuss, Basle, Switzerland. App. filed Sept. 28, 1900. The wire layers are in discs perpendicular to the axis of the coil; the insulation being arranged so that its value between every two turns is proportional to the potential difference.

755,247. MANUFACTURE OF SULPHURIC ACID; Pedro G. Salom, Philadelphia, Pa. App. filed June 17, 1902. (See page 658.)

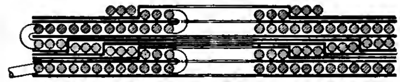
755,282. ELECTROMAGNETIC SEPARATOR; Myron Dings, Milwaukee, Wis. App. filed May 23, 1903. Details.

755,297. AUTOMATIC CIRCUIT BREAKER FOR ELECTRIC TIME OR OTHER SWITCHES; Arthur W. Hutchins, Providence, R. I. App. filed May 15, 1903. Details.

755,302. EXTRACTION OF COPPER FROM COMMINUTED MINERAL MIXTURES; Ernest A. LeSueur, Ottawa, Can. App. filed May 27, 1899. (See page 658.)

755,305. PEAKED WAVE WIRELESS TRANSMISSION; Daniel M. Moore, Newark, N. J. App. filed June 14, 1902. A method of setting up waves of radiant electric energy by producing changes of primary exciting electric potential which, if graphically described as a series of waves, would show waves of highly peaked form.

755,306. ELECTRIC TUBE LIGHTING; Daniel M. Moore, Newark, N. J.



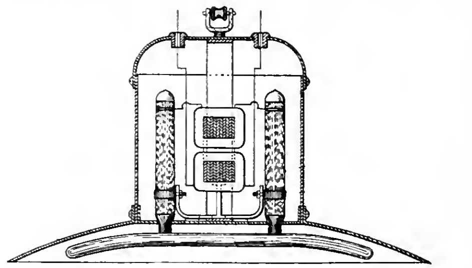
755,229.—Coil for Electromagnet or other Purposes.

App. filed Jan. 19, 1903. The leading-in wires of the tube are in direct connection with the terminals of the secondary of the transformer, the connection being made within a casing inclosing the transformer.

755,307. ELECTRIC TUBE LAMP; Daniel M. Moore, Newark, N. J. App. filed Feb. 6, 1903. A casing containing a transformer and the tubular lamp terminals, that portion of the tube used for lighting, extending through the walls of the casing.

755,320. APPARATUS FOR HEATING AIR; Walter K. Seelye, Dubuque, Iowa. App. filed June 13, 1902. Details of a resistance and valve apparatus for instantaneously heating air on its passage through a dental or other tool.

755,358. RETARDING DEVICE FOR ELECTRIC CIRCUIT BREAKERS; Algernon R. Cheyney, Philadelphia, Pa. App. filed Dec. 2, 1903. An



755,307.—Electric Tube Lamp.

automatic valve controlling the inlet of liquid to a chamber in which the core of the solenoid moves.

755,367. STATIC ELECTRIC MACHINE; Ernest E. Fewkes, Newton, Mass. App. filed June 1, 1903. One or more revolving non-charging generating plates and a revolving charging plate, equalizing combs for all the plates, and electrical connections between the equalizing combs of the charging plate and those of the generating plates.

755,382. DEVICE FOR TESTING ELECTRIC CURRENTS; Charles Oliver, Woolwich, England. App. filed Nov. 29, 1902. A low conductive pencil to be held in the band is fitted with a sliding metallic cap adjustable in position to alter the resistance of the pencil.

755,391. ELECTRIC RAILWAY SHOE; Henry Rosenfeld, New York, N. Y. App. filed Aug. 19, 1903. The contact surface of the shoe has a V-shaped rib and is weighted to remove snow and ice from the rail.

755,393. ELECTRIC CONNECTION; Frank J. Russell, New York, N. Y. App. filed Nov. 6, 1903. Reversible bracket angle-plates are used to compensate for incorrect settings of terminal boxes in a wall.

755,468. RHEOSTAT; Arthur C. Eastwood, Cleveland, O. App. filed Dec. 21, 1903. Wiring connections of a controller are avoided by mechanically fastening the contact fingers to a metal frame to which the resistance circuit is applied and connected.

755,514. FIRING MECHANISM FOR BREECH-LOADING GUNS; John F. Meigs and Sigard A. S. Hammar, South Bethlehem, Pa. App. filed Feb. 2, 1901. Details.

755,537. COIL FOR DYNAMO ELECTRIC MACHINES; Ferdinand Porsche and Ludwig Lohner, Vienna, Austria-Hungary. App. filed July 11, 1902. A coil wound of band conductors and having opposite sides or ends cut away to give it a concave-convex form to fit against the ring of a field magnet.

755,563. AUTOMATIC CONTROLLING DEVICE; Jacob S. Cole, Allegheny, Pa. App. filed July 15, 1903. An automatic switch adapted for electric cranes.

755,577. ELECTRIC VIBRATOR; William MacMillan, New York, N. Y. App. filed July 29, 1902. A circuit changer for vibrating bells in which the contacts are located in a closed box.

Electrical World and Engineer

CONTENTS.

ELECTRIFYING STEAM ROADS.

We have already called attention to the electrification of the Lancashire and Yorkshire steam railroad in England, and last week gave some further interesting data about this work. It is not to be forgotten that outside the Manhattan Elevated this is virtually the largest third rail system in the world, but of course the main interest lies in the change from steam to electricity. This is the first notable example of the kind in England, a country where a great deal more of the same development may be expected, even before it is attempted in this country. Indeed it is striking to note the elaborate figures made by Mr. F. F. Bennett in his recent paper before the British Institution of Electrical Engineers on the electrification of the steam railroads of England. He estimates a total annual expenditure of £13,939,646 or about $65,500,000, and a cost per train mile of 10.0479 penny, with a kilowatt cost of 1.2121 penny. This, he says, shows only an extra profit of 0.29 per cent., which he does not regard as sufficient temptation for making the change. But on the other hand he points to the great increase in traffic, sometimes fourfold, that follows the adoption of electricity, and claims that with an ultimate increase of capital of £300,000,000 to make the change up to its feasible limit of increase, the proportion of net receipts would be raised from the 3.279 per cent of 1901 to 5.1, or an increase in the profits of 1.831 per cent. This would represent an additional profit of £23,558,421 per annum. The complete paper is well worth close study and criticism.

BOOSTER CALCULATIONS.

In dealing with a long trolley feeder that is overloaded, we find that the pressure is unduly low at the distant end, where the feeder connects with the mains. Under these conditions one of two expedients must be resorted to for amelioration: Either more copper must be used or else a higher generating pressure. In the case of a trolley station, it may be impracticable to raise the pressure at the generators. In that event, there must either be more copper or a booster. There must be more conductance in the feeder, or an e.m.f. must be inserted in it. In many cases it is cheaper to put in the booster, and to increase thereby the drop and waste more power in transmission, than to sink investment in the copper and continue to lose the interest on the same. The article on page 687, by Mr. W. A. Del Mar, considers the various conditions controlling the installation and use of boosters.

There are two ways in which boosters may be applied to a trolley system. One is the ordinary way of raising the pressure at feeding points, or increasing the positive pressure. The other is in the application of boosters to the return circuit, in order to keep down the pressure more nearly to that of the ground. Such negative boosters, or depressors, are sometimes called "crushers." The difference, however, between a booster and a crusher is a mere matter of detail, and if instead of a ground return circuit, the return were entirely insulated, the difference would disappear. The value of a crusher is not merely for reducing the apparent drop of pressure in the ground return conductor system, but also for reducing or eliminating the dangers of electrolysis. The computations described for arriving at the most economical booster plant are very interesting. The cost per kilowatt of boosters is manifestly considerably in excess of the cost of generators, since boosters are of relatively small capacity, and require motive power as well as generator power. Boosters also add to the switchboard expense, and the general complexity of a system. Consequently, although boosters have proved a great boon to the electric street railway, they should not be installed without carefully counting the economies of the situation.

SYNCHRONOUS CONVERTERS.

The modern converter is a wonderful machine from the standpoint of efficiency and convenience. It is in very extensive use, particularly in America, and it gives, as a rule, excellent service. It is a very compact machine and very light. That is to say, its output in watts per pound, or per kilogramme, is high relatively to that of the ordinary motor or generator. The reasons for this large output are that the machine is to a great extent a mere revolving commutator, and that during an appreciable part of the time in any alternating-current cycle, the alternating current is directly delivered from the collector rings on one side to the commutator, brushes and direct-current circuit on the other side. Moreover, in the polyphase converter, there is no appreciable absorption of mechanical power. The alternating-current power arriving on one side is converted into direct-current power delivered on the other side, without assuming the form of mechanical power as an intermediary step. In other words, neglecting frictions, the converter is devoid of mechanical torque. In this respect it approaches the conditions of the alternating-current transformer, which is stationary and devoid of torque, but which is, nevertheless, subjected to electromechanical forces of appreciable magnitude. These forces are rendered apparent when the coils are capable of moving relatively to each other, as in "tub transformers." It is surprising how large a proportion of our direct-current supply in large cities comes from alternating-current generators through the medium of converters. The theory of operation of converters thus assumes considerable importance. Part of this theory is covered by the article of Prof. F. G. Baum, appearing on page 691.

The relations between the voltages between collector rings on one side and commutator brushes on the other, are readily capable of being elucidated and apprehended. The heating of the armature winding under the differential action of the alternating and direct currents is, however, a complex matter. It has been worked out by Steinmetz, Child and others. A resumé of the computation is given in Prof. Baum's article, and shows the relative advantage of the six-phase converter. The article also gives the characteristic regulation curves of a particular small polyphase converter when employed as a shunt machine, and when compounded. It is shown that when compounded by the use of a series winding, the pressure at brushes is sustained much better under load than when the machine only employs a shunt field; but that, in order to make the pressure rise, reactance has to be inserted in the external alternating-current circuit. The manner in which the compound winding of the converter can cause the alternating current entering the machine to lead as the load comes on, and thereby force the pressure up at collector rings owing to the negative drop of the leading current in the reactances, is a very interesting well-known proposition.

STROBOSCOPIC METHODS OF OBSERVING AND RECORDING PERIODICALLY AND RAPIDLY VARYING PHENOMENA.

In the January number of the *Journal* of the British Institution of Electrical Engineers is an excellent paper by M. E. Hospitalier on stroboscopic methods of observation and recording. Instruments for stroboscopic observation are called stroboscopes, and instruments which record stroboscopically are called strobographs. The ondograph of the author pertains to the latter class. A commutator is driven, with a definite small amount of asynchronism, by a small electric motor, and the commutator alternately charges a condenser from the periodically varying e.m.f. under test, and discharges the same through a measuring instrument. The latter moves a pen over a rotating cylinder, and, after about 1,000 cycles of the alternating e.m.f. completes a curve that practically represents every detail of variation in the wave.

There are several ingenious mechanical details in the apparatus. One is the avoidance of curvilinear co-ordinates in the traced diagram. When a D'Arsonval galvanometer is fitted with a lever arm and pen, the pen moves on the arc of a circle having for radius the length of the lever. A long arm makes a heavy and unwieldy lever. On the other hand, a short and manageable lever gives markedly curvilinear co-ordinates. In the ondograph, a long balanced pen-holding lever is operated by a short arm on the D'Arsonval galvanometer by a pin-and-slot connection. By this means the rectilinear diagram of co-ordinates is very nearly secured without encountering the mechanical difficulty referred to. By employing an electrodynamometer of the Thomson watt-hour-meter type for the recording instrument, the apparatus may also be made to record the cyclic curve of varying power in an alternating-current circuit, in addition to the curves of cyclically varying pressure and current.

THE ELECTRIC RIGIDITY OF THE ATMOSPHERE.

By far the cheapest and best insulator for high pressures in transmission circuits is air. It costs nothing more than the land beneath. It insulates alike the high-pressure, long-distance systems with many kilovolts, and the telephone wires that throb to vocally responsive voltages of but a volt or two. Of course, air insulation means practically air-and-glass, or air-and-porcelain, insulation, and at the glass or porcelain usually lies the rub. The race for high voltages in recent years has set even the atmosphere at its wit's ends to insulate the wires. Up to forty kilovolts, the spark-leaking distance of which is but a few centimeters, the air gives no trouble at reasonable distances between the wires; but above that limit the air is apt to take alarm and to coruscate with a cylindrical halo or corona that is very expensive to the station manager. The halo of a saint is always assumed by artists to be wattless, but the halo of a high-pressure wire may absorb many watts per foot. Consequently, as sixty kilowatts is already the existing commercial limit of pressure and there is talk of raising this yet further in the not-far-distant future, it becomes necessary to reckon with the air god as well as with the controlling spirits of glass and glazed earthenware. According to our modern views of electrolysis, air insulates like pure water, because it is in a stable molecular condition. There are no atomic valencies to satisfy in ordinary air or water. All the atoms are satisfied. But a disrupted molecule or a chipped atom thirsts for satisfaction and is subject to forces in electrostatic fields.

There are, however, limits to the stability of molecules. Jostle air molecules violently enough and they break up, or ionize. At the same time ozone is produced. At ordinary temperatures, and in the absence of energetic radiations, air molecules are supposed to jostle about with velocities of kilometers per second, but their collisions do not break up more than a few molecules per billion per second. Add, however, an electrostatic field, and the stability under collision is reduced. Lower the atmospheric density, so as to lengthen the mean free path, and give the electric flux more room to act between collisions; also increase the temperature of the air, and its mean velocity of molecular swing and the stability may be overcome. The air ionizes rapidly when the critical limits are reached, and the indicate that the critical voltage of brush discharge descends with from the wires. The recently published researches of Prof. Ryan indicate that the critical voltages of brush discharge descends with the air pressure, so that on transmission lines passing over high mountains the voltages that may be carried are markedly less than that which the same construction would admit of at sea level. Moreover, the danger of brush discharge diminishes with the size of the conductor, a large wire permitting of a higher voltage. This fact favors aluminum wires. After all, at sea level, 100 kilovolts can apparently be carried with wires four feet apart, when the area of each of the wires is 40,000 circular mils. Since it is the top of the wave that counts, for producing halo, a flat-topped wave of voltage is less addicted to brush than a sine-wave or a peaked-wave, for the same effective voltage. On the other hand, the peaked-wave favors the reduction of hysteresis loss in transformers, while the sine-wave favors the elimination of resonant effects by harmonics.

The Question of Fire Risk.

The Institute discussion at the March meeting took a turn which most forcefully impresses the importance of precautions against fire. Modern electrical generators have been so far perfected as to make down-right breaking down of their functions extremely unusual. But it is not unusual for stations to be wholly or partly shut down by accidents, and fire is no unusual cause or concomitant of such occurrences. In fact, the fire risk, while enormously less than it was a few years ago, is still a consideration of much importance. It ought to be, and in fact is, no difficult matter to build a fire-proof station, but in practice fire-proof stations in any proper sense of the term are rare. As a rule, either the designing engineer is thinking of something else or somebody steps in with the blundering notion of making the station pretty and the result is a fire trap at some point. If there is any place in which the Socratic criterion of beauty should be rigidly applied, that place is an electric power station. But when it comes to fire-proof construction, somebody generally protests with serious results. Let us consider seriously the design for a station with especial reference to fire risks and see what safe construction implies. In the first place, the general shell of the plant is an easy task. Whether it be for a water power plant or a great steam-driven station, walls of stone, brick or concrete, with iron roof and floor beams, if there be more than one story, give a construction as safe from fire as anything yet devised by man. Next comes the serious question of floors. Wood which is commonly used implies a grave fire risk, particularly as it is certain sooner or later to become saturated with oil. Tile and concrete make good floors, but are not entirely free from fire risk when oil soaked.

Perhaps the best combination is as follows: For all floor not so situated as to be exposed to oil from the machinery, tile or concrete, and near and around the machinery, metal or glazed tile covered by removable grids of fire-proofed wood. It is a question to what extent fire-proofed wood can be advantageously used, but it is certainly safe enough if not used in large amounts, and there is no need of covering large areas with it. Starting with radical fire-proof construction of such sort, danger to the building as a whole is pretty well eliminated. But in station work continuity of service is of the first importance and precautions must be directed next at the apparatus so that fire shall not be able, even if in the form of an electric arc, to do damage of serious character. For convenience, we may divide the whole equipment into four parts—generators, transformers, leads and switchboard, each of which should be considered with reference to the prevention of fire risk. As to the generators, they are fairly safe except in the case of a prolonged short-circuit, and when internal damage occurs it is generally not very extensive. They are not likely to be injured seriously by external causes if the generator room floor is fairly non-combustible. In a modern large station there is often danger, more or less acute, of getting a short-circuit inside the protecting switches on the board and it is a good rule to get a safety switch cut in as near the generator as practicable. The use of revolving-field generators has greatly reduced the danger of disastrous short-circuits, and such machines form the most reliable part of the plant.

The transformers are far more exposed to danger of fire external and internal than are the generators. The discussion of Mr. Rice's excellent paper brought out the facts in the case very forcibly. The general consensus of opinion was that upon the whole oil transformers were decidedly less severe fire risk than air-blast transformers. The oil, as Mr. Townley in particular forcibly pointed out, is very far from being oil in the ordinary sense of the term. It is inflammable only with great difficulty and will put out an arc started in it under ordinary circumstances without the slightest danger of fire. It is practically merely a liquid insulator, upon the whole less inflammable and less seriously affected by heat than most solid insulators. Still it can be set on fire and then burns fiercely enough. The danger of giving off explosive vapors, to which frequent reference was made in the discussion, does not seem to us considerable owing to the very high boiling point of the oil and the density of the vapor, which makes it far from easy to get air enough for an explosion. For this reason the suggestion of oil tanks strong enough to stand [illegible]00 pounds per square inch internal pressure seems unnecessary, a relief valve in the top of a thin case appearing to us adequate protection. Provision for drainage of the oil in case of serious trouble seems highly desirable, and if the transformers be slightly raised above the floor, and the latter be sloped to drain outside the building into a sand pit no great harm can be done. It might not be a bad idea to put a plug of fusible metal in the base of the case to let out the oil into the scuppers before the flashing point could be reached, but with proper drainage the value of the oil in protecting the coils is so considerable as to make one think twice before letting it out so long as the case holds together. It makes no particular difference whether the transformers are in the generator room or a separate room, so long as oil from the transformers cannot run freely about.

Trouble with insulating the leads from the generator room to a separate transformer room must be taken into consideration. They may be, and in many stations are, a graver fire risk than the transformers themselves. They are usually of fairly high voltage and are very apt to be crowded together in a needless straining after compactness. We have a good deal of sympathy with Mr. Mershon's preference for bare conductors and his lament that our modern oil switches are so bulky to install. Oil switches are by far the best thing to use with even moderately high-voltage circuits, owing to their comparative safety in the matter of setting up surging, but they certainly are clumsy, as in fact any switch for very powerful circuits must be. In large sizes they add considerable difficulty to planning the switchboard, but they are necessary. They are, however, free from the danger of appalling leaps of the current such as are produced by air switches, and which in many plants render the switchboard by far the severest fire risk in the building. We have seen stations in which the switchboards were a constant peril both to life and to property. The commonest fault is a foolish effort at compactness, resulting in crowding the board with apparatus and incurring great risk of short-circuits or of arcs formed fierce enough to ruin the board and shut down the plant. The safest rule is to take plenty of space and to put the board where it is well lighted and fully accessible. The modern electrically or pneumatically-operated switches aid immensely in safe design, but full advantage should be taken of the facilities thus acquired for avoidance of crowding. A plant is as weak as its weakest point and a fire on the board may put it out of service for days. One of the most encouraging features of the papers and discussions under notice is the general unquestioning acceptance of these high voltages as an essential part of the modern programme, susceptible of proper engineering treatment, with a steady tendency towards improvement and the minimization of danger and damage.

A. I. E. E. International Electrical Congress Reception Committee.

The first meeting of the International Electrical Congress Reception Committee of the American Institute of Electrical Engineers was held at 12 West Thirty-first Street, N. Y., Thursday evening, March 24. A large representation of the committee was present; also Mr. George G. Ward, local honorary secretary of the Institution of Electrical Engineers, members of the board of directors, and members of the transportation committee, who had been invited to attend. Chairman Lieb proposed the following itinerary:

The foreign guests of the Institute are expected to arrive in New York previous to September 3, 1904. After that date the itinerary will be as follows:

Sunday, September 4, 1904, New York City.—This day will be spent in a steamer ride up the Hudson River, possibly as far as West Point.

Monday.—The visitors will be entertained by the corporations representing the electrical industries of New York City, including a visit to the power houses of the Rapid Transit Subway Company, the Manhattan Railway Company, the Metropolitan Street Railway Company, the New York Edison Company, the exchanges of the New York Telephone Company, and other points of engineering interest. In the evening there will be a formal reception to the foreign visitors under the auspices of the Institute.

Tuesday, Schenectady, N. Y.—The party will leave New York on Tuesday morning for Schenectady, where they will be received and entertained by the General Electric Company, leaving for Albany in the afternoon. P. M., Albany, N. Y.—Leave Albany in the evening for all-night trip to Montreal.

Wednesday and Thursday, Montreal, Canada.—Reception at McGill University, Montreal, and visits to the important power transmission plants in the vicinity, leaving Montreal Thursday evening by boat or train for Niagara Falls.

Friday, Niagara Falls, N. Y.—Visit to the Falls and the important power houses and electrical industries of the locality. Leave Niagara Falls Friday evening for Chicago, arriving Saturday morning.

Saturday, Chicago, Ill.—Visits to important power houses and local points of interest. Leave Chicago Saturday evening for St. Louis, traveling all night.

Sunday, September 11, St. Louis, Mo.—To be spent in St. Louis.

Monday.—Opening of the International Electrical Congress at 10 o'clock A.M., with joint sessions of all of the sections.

Wednesday.—Special joint session between the American Institute of Electrical Engineers and the British Institution of Electrical Engineers, to which all foreign guests are invited.

September 13, 14, 15 and 16.—Sessions of the various sections of the Congress, with sessions each day from 9 to 12 A.M., and from 1.30 to 4.30 P.M.

Saturday, September 17 (Afternoon).—Closing general sessions of all sections of the International Electrical Congress. (Night.)—Leave St. Louis for Pittsburg, arriving late Sunday afternoon.

Monday, September 19, Pittsburg, Pa.—Reception and entertainment by the Westinghouse Company, and visits to important and interesting local industries. Leave Pittsburg Monday night and arrive at Washington Tuesday morning.

Tuesday, Washington, D. C.—Inauguration of the National Bureau of Standards at Washington and visits to places of local interest.

Wednesday, Philadelphia, Pa.—Visits to important power houses and points of interest. Leave Philadelphia for Boston in the afternoon via boat—Fall River Line.

Thursday, Boston, Mass.—Visits to power houses Harvard University, Massachusetts Institute of Technology and places of local interest. Leave Boston Thursday night for New York by boat.

Friday.—Unassigned.

Saturday, September 24.—Return home by some of the party. Ladies are expected and special arrangements will be made to insure their comfort.

The details of the tour as suggested were thoroughly discussed, and while there was a feeling that it would be a severe tax upon the visitors, it was difficult to see how the trip could be curtailed without omitting some desirable and important features. It was voted that the committee be thanked for the programme as outlined, and that it be accepted with the recommendation that if possible, the chairman of the transportation committee should arrange that there be some plan adopted by which as many sleeping cars as might be necessary would be provided for the special train on the return trip; and that such persons as desired, have the privilege of alternative return routes on regular trains. In case this cannot be arranged, the plan to be adopted as presented.

The following executive committee was appointed: John W. Lieb, Jr., chairman; F. J. Sprague, vice-chairman; J. C. Barclay, J. J. Carty, F. W. Jones, H. Ward Leonard, E. H. Mullin, L. B. Stillwell, H. G. Stott, Calvert Townley, Geo. G. Ward, J. B. White. Local committees at the various points to be visited will be subsequently announced by the chairman.

Incandescent Lamp Combination.

Note was made in these columns last week of the meetings held by the incandescent lamp manufacturers in this city and Cleveland in regard to patents, prices, policy, etc. There is not a great deal to be added to what was then outlined. Under the guidance of Mr. F. S. Terry, of the National Lamp Company, the manufacturers remained in session at the Manhattan Hotel in this city until the end of the week, when important results were reached. Some thirty infringement suits under the Malignani, Howell and Edison patents had been brought against manufacturers, jobbers and others, and these may be regarded as amongst the moving causes for the combination, although there had of late been considerable discussion on the subject also from the standpoint of ruinous rate-cutting. Be the reasons what they may, the following lamp manufacturers have now taken out licenses dating from April 1, granted by the Edison Electric Light Company and the General Electric Company, and all suits against licensees or their representatives have been discontinued. The list of licensees is as follows: Downward Light Electric Company, New York; the Sterling Electrical Manufacturing Company, Warren, Ohio; the Brilliant Electric Company, Cleveland, Ohio; the Banner Electric Company, Warren, Ohio; the Franklin Electric Manufacturing Company, Hartford, Conn.; the United States Incandescent Lamp Company, St. Louis, Mo.; the Standard Electrical Manufacturing Company, Niles, Ohio; Capital Electric Company, Denver, Colo.; Gilmore Electric Company, Boston, Mass.; Liberty Electric Company, Pittsburg, Pa.; Warren Electric & Specialty Company, Warren, Ohio; the Colonial Electric Company, Ravenna, Ohio; Shelby Electric Company, Shelby, Ohio; Bryan-Marsh Company, Marlboro, Mass.; the Buckeye Electric Company, Cleveland, Ohio; Munder Electric Company, Springfield, Mass.; Sunbeam Incandescent Lamp Company, Chicago, Ill.; Columbia Incandescent Lamp Company, St. Louis, Mo.; Independent Incandescent Lamp Company, Cleveland, Ohio; New York & Ohio Company, Warren, Ohio; Fostoria Incandescent Lamp Company, Fostoria, Ohio; General Incandescent Lamp Company, Cleveland, Ohio; National Electric Lamp Company, Cleveland, Ohio.

It will be noted that the Sawyer-Man Electric Company is not in the combination and that company has already issued a statement to the public to that effect. Four other concerns are not included, although it is intimated that some of them may still come in. It is claimed that over 99 per cent. of the lamp production of the country is represented by the capacity of the "pool" licensees. The present annual consumption of lamps is put at 45,000,000. The total productive capacity of the existing factories is placed at about 65,000,000.

With regard to concerns not yet included the statement is made that all in the business on April 1 have the option to come in on taking out a license, agreeing to the scale of prices, and consenting to pay the royalty. No information is vouchsafed as to the royalty, but it is rumored to be a gross charge of ½ cent per lamp, and an actual ¼ cent net. There is also a report that all members of the combination as licensees agree to bind themselves to sell their product at a certain flat price—say 16 cents—and not below; and it is also reported that with this and territory as a basis a certain scale is to apply to central stations, jobbers, isolated plants, etc. The question is raised as to what would be the course adopted toward a new manufacturer coming into the field after April 1 and willing to be licensed, pay the royalty and maintain rates; or, on the other hand, one who would be willing to take out a license, but objected to maintaining the proposed schedule of prices. Extremists urge that an illegal condition "in restraint of trade" might easily arise under the operation of this new license and contract. Meantime the present manufacturers appear to be very well satisfied with the close of the rate war and the protection and immunity which their license affords them. It is understood that they may form an association among themselves for the cultivation of intimacy and closer intercourse.

Steam Turbine and Other Features of the Port Huron Light and Power Company's Station.

By James E. Davidson.

THE Port Huron Light & Power Company was one of the first central station companies to contract for a Curtis steam turbine, a 1,500-kw turbo-generator having been ordered in October, 1902, which has been in operation several months. On account of the interest in the steam turbine at the present time, a description of this company's installation may not be without interest. Before going into the details of the steam turbine outfit, however, a review will be made of the general conditions in the station in which it is installed.

Port Huron is a city of about 20,000 inhabitants, situated at the southern end of Lake Huron on the St. Clair River. It is generally known to the outside world as the "Tunnel City," on account of the great international tunnel of the Grand Trunk Railway from Port Huron on the American side to Sarnia, on the Canadian side of the river. Among other industries is a shipbuilding yard, employing about 500 men. The whole yard is operated by electric motors, some sixteen in number, with current supplied by the Port Huron Light & Power Company. A traction engine and farm machine factory, together with a malleable iron factory, and a saw factory, employing 600 men, operate their plants with three-phase induction motors, ranging from 7½ to 75 hp. There are a number of other important industries, including the locomotive and car building shops of the Grand Trunk Railway. Gratiot, Huronia, La Salle and Keewahdin Beaches are large summer resorts just beyond the city limits, where many Southern people make their homes during the summer months. This company furnishes light to about 100 cottages on these beaches. Then, too, Port Huron has a very fine railway system, having cars run from one end of the city, at which point is located the principal railroad depot, on the south, to the beaches above mentioned on the north, covering a territory of about seven miles in length. During the summer months ten-minute car service is given over this territory. This is also the northern terminal of the Rapid Railway system, which runs cars hourly from Detroit, Mich. These cars are interurban type with 300 hp in motors installed under them. The Port Huron Light & Power Company furnishes power to the city railway, which operates in the neighborhood of twelve to fifteen cars per day, and also furnishes power for the Rapid Railway system in the city and about one-half mile outside of the city limits. Taken altogether, the company is covering the light and power field very fully, as can be judged from the foregoing.

The light and power business in Port Huron was started by the Excelsior Electric Company in 1885. The old plant of this company was burned twice, as a result of which experience the present station is entirely fire-proof. In June, 1901, the company was reorganized under the name of the Port Huron Light & Power Company, at which time a thirty-year franchise was obtained from the city. The officers of the old and new companies, which have remained unchanged from the beginning are: Henry McMorran, president; Charles F. Harrington, vice-president, and W. F. Davidson, secretary and treasurer.

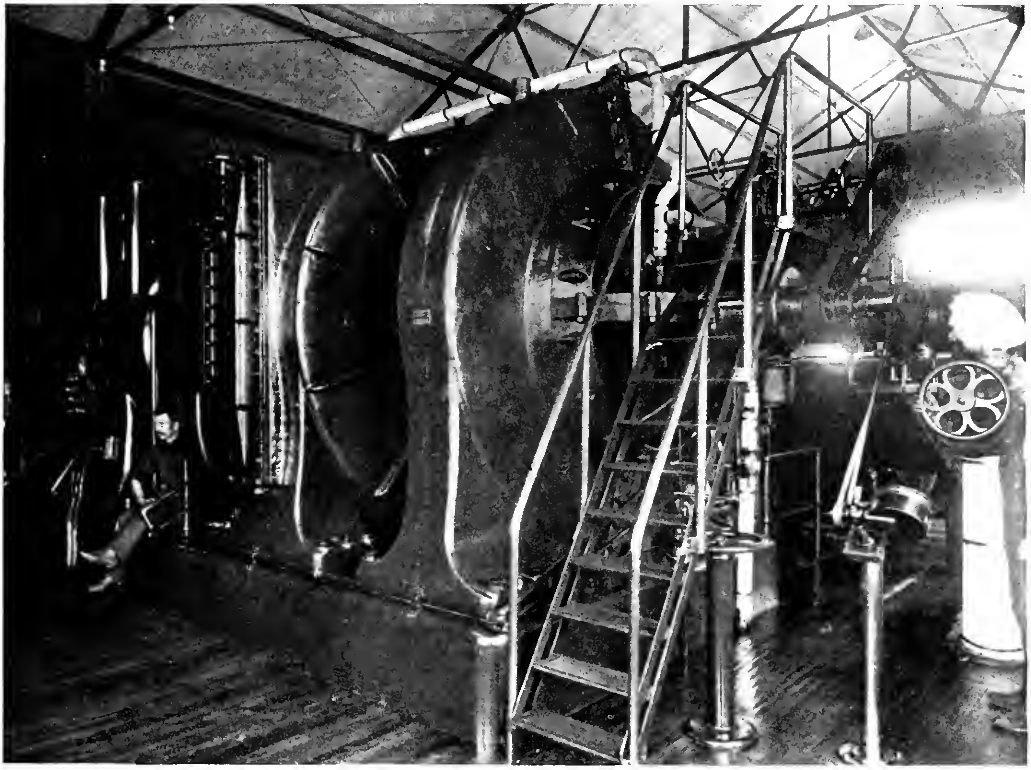

Fig. 1.—General View of Curtis Horizontal Turbine, Port Huron, Mich.

The property at the time of the reorganization consisted of a fireproof building 125 ft. x 138 ft., built about five years prior to this time. This building contains two compound condensing 500-hp engines, and one tandem compound condensing 1,200-hp engine; also three 500-hp and one 250-hp Stirling boilers, two Worthington feed pumps, one Cochrane heater and a Worthington jet injector. On the top of each of these boilers there are installed Crane automatic valves which close automatically in case the pressure changes in any of the different boilers. For example, if a tube is blown out, this boiler is immediately cut out from the others so there will be no interruption to the plant by other boilers losing their steam and water. The generating equipment is driven mainly by Hill's system of pulleys from line shafting, and consists partly of direct constant-current arc dynamos, partly of 500-volt railway and power generators, and partly of 60-cycle, 1,150-volt, three-phase generators. Since the 1,500-kw turbo-generator was installed, a series alternating-current arc system has been planned to do away entirely with the direct-current arc dynamos.

Direct current at 550 volts is sold for the operation of the street railway system and for commercial power within one mile radius of the plant. For factories situated some distance from the power house in a factory district called "South Park," power is transmitted at 10,000 volts, which is stepped down by transformers to 230 volts for

FIG. 2.—GENERAL VIEW OF PORT HURON PLANT.

the operation of three-phase induction motors. At different localities on the 10,000-volt transmission line are four brick transformer houses, in which the step-down transformers are installed as well as lightning arresters, and marble primary and secondary switchboards. The three-phase generators in the station are all wound for a voltage of 1,150, which is that of the primary distributing system of the general lighting and power business of the city. The lighting secondaries are 115-volt. For street lighting and commercial arc lighting, the 6.6-amp. series enclosed arc has been adopted.

To accommodate the new turbine unit, an entirely new portion of the plant adjoining the old plant was built. This is 40 x 80 ft., with a 9-ft. basement. The interior finish of this building is as follows: Maple hardwood floor, wainscotted with dark green terra vitra tile, and the rest of the side wall is finished with terra cotta pressed brick. All the machinery and iron work is painted deep blue green with vermilion and white trimmings. The machinery in the old building is also painted in the same manner. This addition is shown in the foreground in the general view of the plant, Fig. 2, and its position is shown on the plan, Fig. 3.

In adding to the plant, an ingenious plan has been worked out whereby the new turbo-generator outfit may operate both the old and new portion of the plant as long as the load is not too great. By this plan the turbo-generator operates certain three-phase generators as synchronous motors in the old plant, which motors, in turn, drive through a line shaft the necessary direct-current machinery to keep up the service. If necessary, in order to carry peak loads, or if the turbo-alternator is stopped, the engines in the old plant are started up so as to drive the line shaft and drive the synchronous motors as generators as well as the direct-current apparatus. The load can be thrown from either plant to the other without the slightest interruption to service.

The 1,500-kw turbo-generator consists of a Curtis turbine driving an alternating-current generator, the latter being a three-phase, 60-cycle, 1,150-volt machine. The unit runs at 720 r.p.m. An Alberger surface condenser guaranteed to maintain 28 in. of vacuum has been installed. This Curtis turbine unit, as can be seen from Fig. 1 and Figs. 4 to 6, is of the horizontal shaft type. The piping plant is shown in Fig. 8. Steam enters the turbine through an 8-in. pipe. The governing is accomplished at five ports, the number of ports opened depending on the load. Descriptions of the detailed construction of the Curtis turbine have appeared from time to time in these columns. There are two stages in this turbine, with four revolving discs in each stage. The bearings are sealed against air by a pocket of steam and carbon collars. To lubricate the machine, an oil pump is operated by a leather belt from a pulley on the turbine shaft between the generator and the second stage. The oil is pumped to the bearing through a 5/8-in. brass pipe and returned through a 1½-in. pipe. Before returning to the pump, the oil passes through a water cooler. This cooler consists simply of a water tank with a coil of copper pipe in it through which the oil circulates. There has not been the slightest trouble from heated bearings. The oil at the pump has a temperature of 120 to 130° F.

The turbine is equipped with a mechanical and also an electrical governor. The mechanical governor, which is the emergency governor, is set to operate a butterfly valve when the speed reaches 800 r.p.m., or 50 revolutions above normal, when the governor trips a weight which closes the butterfly valve. This emergency valve can also be operated by hand. The electric governor is the one used for the ordinary governing. The governor shaft of the electric governor is run by a 3-in. leather belt from the turbine shaft. The governor shaft runs about 200 r.p.m. and is equipped with the regular fly-ball governor. When the shaft is above normal speed, the sleeve of the fly-ball governor makes an electrical contact. When it is below speed, another electrical contact is made. Supposing that the turbine is above normal speed and the "high-speed contact" is made, a circuit is established through a magnetic clutch which connects the governor shaft with the port valves, and which runs the governor valves down so as to close some of the row of ports. When the speed is below normal, the "low-speed contact" on the governor operates another magnetic clutch, which causes the governor shaft to operate the valves to open the ports.

This arrangement is, of course, radically different from the balanced solenoid valves very recently used on large Curtis turbine units. The steam ports open into nozzles, and closing of steam ports effects the shutting off of nozzles. There is thus no throttling action, as a nozzle is either wide open or closed, hence there is no such loss of efficiency as would occur if the steam supplying a nozzle were to

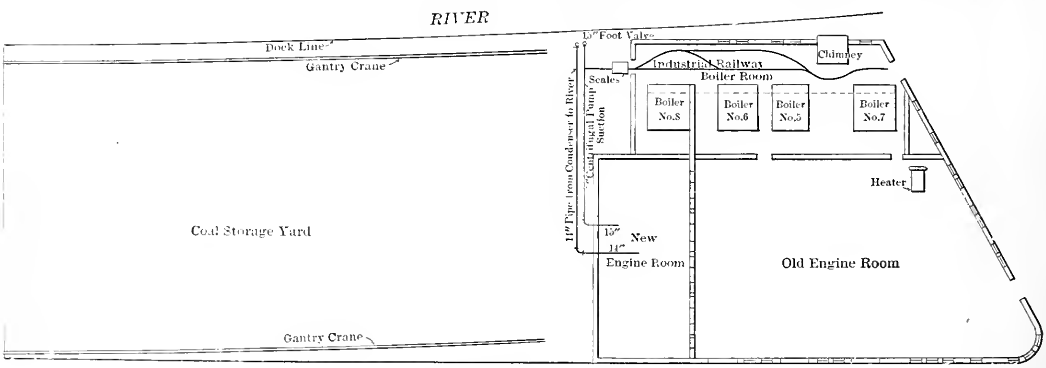

FIG. 3.—GENERAL PLAN OF BUILDINGS.

be throttled so as to lower its velocity at the nozzle. The regulation of speed with this governor with a street railway load varying from 150 to 500 kw, operated together with the other services given by the company, consisting of 500-volt power service, incandescent lighting and induction motors, is within 1.4 per cent. This excellent regulation holds its own during the heavy snow storms that they have had to contend with in their street railway work, and the turbine kept its regulation while the big interurban cars bucked heavy snowbanks, as well as the city line. At times the load would vary from zero to 1,500 amp., and the turbine would take care of this load without any perceptible change in speed. In the second stage of the turbine there are two sets of ports with governor valves instead of one set as in the first stage. The current for the operation of the governor magnets is taken from the exciter circuit.

As the high vacuum which it is considered expedient to maintain in connection with a steam turbine is a matter upon which some steam engineers have had doubts, it is interesting to note that with a load of 1,000 kw, and intake water at 72°, 28 in. of vacuum has been maintained continuously. With the same load and cooling water temperature at 58°, $28\frac{5}{8}$ in. of vacuum has been maintained with

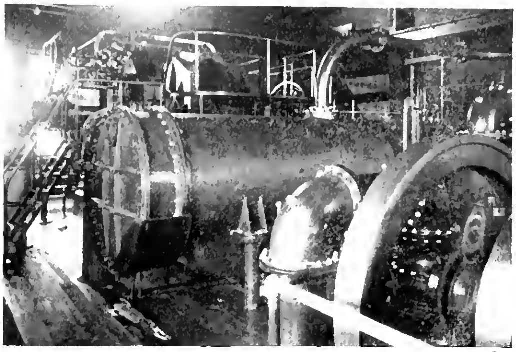

FIG. 6.—CONDENSER.

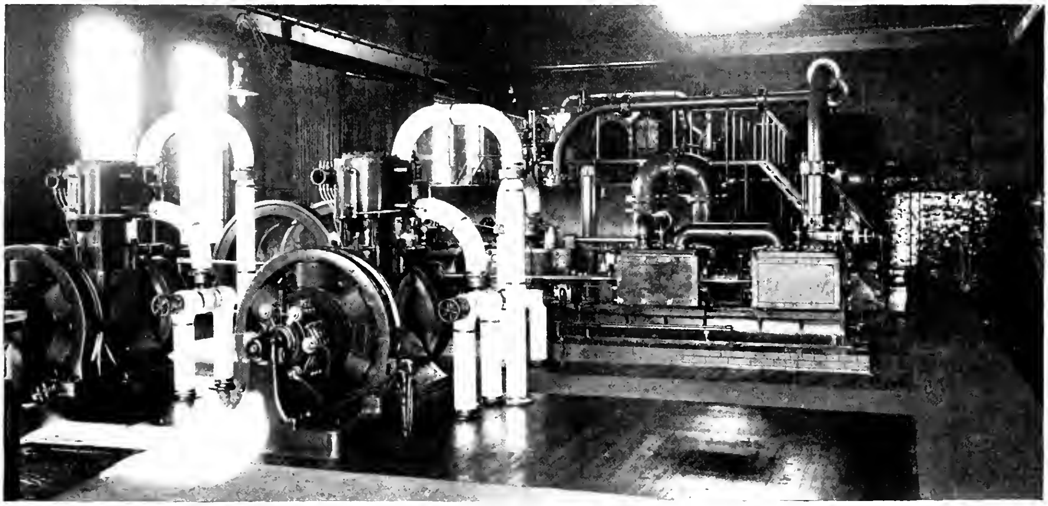

FIG. 4.—GENERAL VIEW OF ENGINE ROOM, SHOWING TURBINE WITH CONDENSER AT REAR AND EXCITERS.

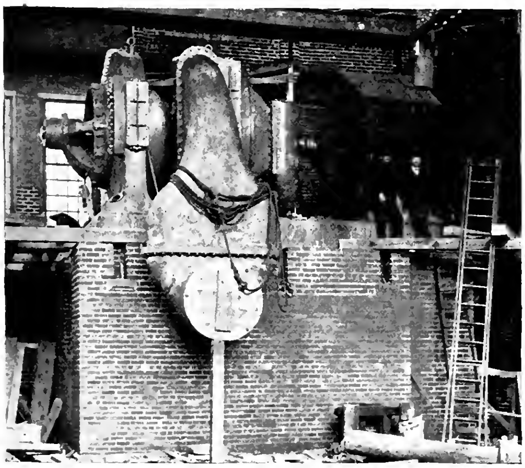

FIG. 5.—TURBINE UNIT IN PROCESS OF INSTALLATION.

the barometer reading $29\frac{3}{4}$ in. During the winter months the vacuum has been maintained with but very few exceptions above 29 in., and fluctuates only with the barometer. Readings within one-quarter to one-half inch of the United States Government barometer readings are obtained at all times. This, of course, is with the cooling water in the neighborhood of 40° F. By closing the valve between the condenser and the vacuum pump, a vacuum within $\frac{1}{4}$ in. of barometer pressure has been obtained. A vacuum of $28\frac{1}{2}$ in. has been recorded with the exhaust from both exciting engines going into the condenser, and the vacuum pump discharging into the condenser, and with the exhaust from the circulating pump engine going into the heater. A mercury tube and not a gauge was used in all these tests.

The Alberger surface condenser (shown in Figs. 3 and 5) with which the turbine unit is equipped is supplied by a 15-in. centrifugal pump made by the same company. This centrifugal pump is driven by a standard Westinghouse $8\frac{1}{2}$ x 8 engine direct-connected to the pump. The water is pumped from the hot well to the heater by a duplex pump. Circulating water is taken from a well open to the river. This well has cement walls 12 in. thick. The water is let in from the river through a 16-in. cast-iron pipe. The well is divided by a screen partition with $\frac{3}{8}$-in. mesh, the inflow from the river being on one side of the screen and the suction from the circulating pump on the other side. The circulating pump suction is a 16-in. cast-iron pipe. A 16-in. free exhaust to the atmosphere is provided so that the turbine can be run non-condensing. An automatic relief valve is provided in the turbine exhaust which automatically opens the exhaust when the vacuum is lost. The exhaust of the auxiliary engines can either be condensed or sent to the feed water heater. Condensed steam from the turbine is usd as far as it will go for feed water. The air cylinders of the vacuum pump are water jacketed. The jacket water is also run into the feed water supply, and furnishes sufficient extra feed water. The steam pressure carried on the turbine unit is 150 pounds. Standard extra heavy pipe is employed, with brass corrugated gaskets. A receiver 5 ft. long and 3 ft. in diameter, made by the Jenks Ship Building Company, which erected the piping, is placed just before the live steam pipe enters the turbine. The drip is taken from the bottom of this receiver. The steam from the boilers enters near its top and the pipe to the turbine leaves directly at the top. A Kiley standard trap is used on the receiver. Crane valves are used throughout except the throttle valve on the turbine, which is a Chapman gate valve. The six-inch air discharge on the vacuum pump is outside the building.

In the operation of the turbine there has been no trouble from the so-called end play after once setting the intermediate stationary vanes. A tachometer is located on the shaft near the throttle and is in operation all the time. Should anything happen to the governor, fair regulation can be obtained by pulling the switch to the governor and operating the valves by a hand wheel, using the indications of the tachometer as a guide. An iron platform with steps leading to it and with a brass guard rail around it, has been built so that the engineer can easily get at the governor, this being about the only part of the apparatus that needs attention, as the rest comes very near taking care of itself.

The steam pressure is reduced for the exciting engines and air pumps. The object of this is to make it possible, in cases of emergency, when the boiler pressure falls, to open a by-pass valve so as to increase the pressure on the exciter unit and keep the exciting current up to its normal value, even though the speed of the generator is decreased. The same thing can be done with the vacuum and circulating pumps so that the vacuum will not be reduced.

The expense for oil has been reduced over 50 per cent. by the running of the turbine as compared with the engines in spite of the fact that at all times three auxiliary engines are operated. As to long runs, two of the hardest months in the year, November and December, the turbine was operated almost 1,500 hours without stopping. It was then stopped to clean out the surface condenser.

Another advantage this company has noticed in its turbine over engines, and a point that has not been usually considered, is that the turbine will maintain its speed and run at one-half its capacity with steam pressure at the boilers as low as eighty pounds.

The exciter sets (seen in the foreground, Fig. 3) are two 30-kw. General Electric standard direct-connected, high-speed marine sets, giving 240 amp. at 125 volts. The engine is 11 in. x 8 in. and runs at 305 r.p.m. Either one of these is sufficient to excite all the alternators in the plant. A Tirrill regulator made by the General Electric Company, which regulates the generator voltage by interrupting the exciting current, maintains the voltage within a variation of 1/4 volt in spite of the fluctuating load on the turbine. The turbine speed can be reduced to about 33 per cent. without any decrease in the voltage, as the Tirrill regulator will increase the exciting current to take care of this decrease in speed.

The turbine is operated somewhat after the following manner in every-day work: Supposing the turbine to be at rest, the condensing apparatus and exciter are put in operation. The by-pass valve around the throttle valve on the turbine is opened enough to admit live steam for warming it up for a period of about twenty minutes. At the end of that time the machine turns over slowly and in five minutes more is brought up to speed. The steam seal for the bearings is next admitted.

In the old portion of the plant a Russell engine is driving a 300-kw, alternating-current generator and three 500-volt, direct-current generators. A Ball engine is driving a 550-kw railway generator. Both engines transmit their power first to a line shaft. A switchboard attendant puts in the synchronizing plug for synchronizing the 300-kw alternator with the 1,500-kw turbo-generator. The engineer is at the throttle of the Russell engine, and an oiler is at the clutch that connects this engine with the line shaft. A Lincoln synchronizer is used to indicate when synchronism is obtained between the two alternators, and they are then thrown together. After they are thrown together a clutch connecting the Russell engine with the line shaft is opened, so that the engine can be stopped. The line shaft runs through the driven pulley of this engine in a quill. The 300-kw alternator which was a moment before running as a generator is now running as a synchronous motor driving the line shaft. That portion of the shaft being run by the Ball engine is now connected by a clutch to that portion of the shaft which is being run by the 300-kw synchronous motor. The clutch on the Ball engine is then thrown out and the Ball engine stopped. The line shaft is then being driven by the 300-kw synchronous motor, which in turn is supplied with power from the 1,500-kw turbo-alternator. The line shaft is running the generators for 500-volt power service and street railway service.

In the afternoon, when the direct-current series arc service is to be started, a 100-kw synchronous motor is started with a compensator, and this drives two Brush arc machines. A second 300-kw alternator is started by throwing in a clutch connecting the section of shaft to which it is belted to the section of shafting being driven by the 300-kw synchronous motor. The second 300-kw machine, when up to speed, is thrown in parallel with the turbo-alternator and then becomes driven also as a synchronous motor and supplies power to drive five 50-light Thomson-Houston and one Brush arc machines. The two 300-kw alternating generators or motors are located at opposite ends of the line shaft, and when they are in operation most of the line shaft can be cut out on account of the position of the driven machines near the ends. Under these conditions of operation, of course the three-phase power circuits as well as the incandescent lighting circuits are taken from the 1,500-kw turbo-alternator. The power factor of the alternator is kept up by giving the synchronous motors a leading current by heavily exciting their fields. It is easy to determine when the adjustment of the synchronous motor fields is such as to bring the power factor of the turbo-alternator close to 100. The excitation of the fields is raised gradually, and as the power factor approaches 100, the ammeter indicates less and less until, when the power factor passes 100 the ammeter needle will again rise. In other words, the synchronous motor fields are adjusted at the point which will give the lowest indications on the ammeter of the turbo-alternator.

A 325-kw motor-generator set which has been in operation two months does away with the operation of considerable line shafting

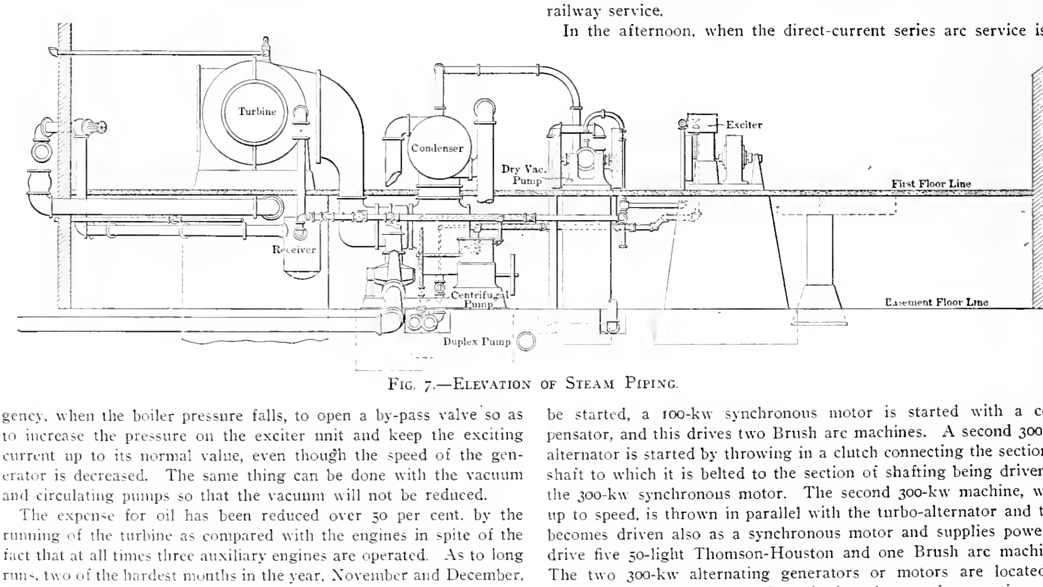

FIG. 7.—ELEVATION OF STEAM PIPING.

formerly used to drive 500-volt, direct-current generators. This consists of a 325-kw synchronous motor of 60 cycles driving a 550-volt, direct-current generator. By operating this set during most of the day, the line shaft can be entirely stopped, and by stopping the line shaft results have been obtained that have been astonishing; that is, in saving at the coal pile. The company never realized the power that it took to operate this line shaft.

The switchboard, Fig. 8, which is in the old portion of the plant, is mounted on an iron framework, which reaches the entire width of the building, and the floor of the switchboard gallery is on a level with the turbine room. Three sets of stairs lead to the switchboard gallery. The gallery floor is of maple. The posts on the platform are of oxidized copper, and the railing is of two-inch polished brass. The switchboard panels, twenty-one in number, are of marble. The board is 49 ft. 8 in. long with panels 90 in. high.

Beginning at the right, Fig. 8, are two direct-current, ten circuit arc panels. One of these is a positive board and the other a negative. At the left of these are two single-phase lighting circuit panels, 24 in. wide, with fuses, I. T. E. circuit-breakers and double-pole, single-throw, 300-amp., quick-break switches, controlling four circuits. The receptacles on these panels were for connecting different circuits to various machines when the generators in the station were single-

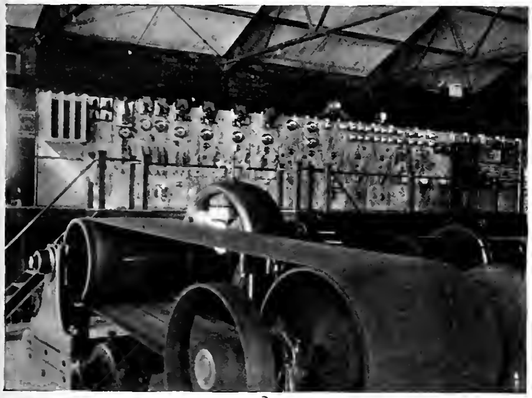

FIG. 8.—VIEW OF SWITCHBOARD.

phase and not operated in parallel. Now, all single-phase lighting is taken from one of the three phases, thus obviating the trouble from unbalancing the phases. It will be remembered that this company has a large induction motor load and that further a large per cent. of the capacity of the three-phase generator can be obtained from one of the phases.

The next panel is for controlling the secondary side of the step-up transformers. It contains one triple-pole switch and two polyphase recording wattmeters. One of these wattmeters records the energy on the high-tension transmission line to the South Park factory district, and the other measures that supplied to the 300-kw synchronous motor which drives the arc machines.

The next two panels (6th and 7th from the end) are generator panels for the 300-kw alternators, which are operated either as generators or motors. Each of these panels contains three 300-amp. horizontal edgewise ammeters, one voltmeter, 1,150-volt ground detector, synchronizing receptacle, synchronizing lamps, 200-amp., double-pole, double-throw exciter switch, and a 500-amp., 2,500-volt, three-pole, single-throw oil brake switch.

The eighth panel, which is for the 1,500-kw turbo-alternator, is 22 in. wide. On top are mounted a Lincoln synchronizer and synchronizing lamps. Mounted on the panel are three 1,500-amp. ammeters, two 1,500-kw indicating wattmeters, one 175-volt voltmeter, a synchronizing receptacle, a 200-amp., single-pole, single-throw exciter switch, one 2,500-volt, 1,200-amp., three-pole, automatic oil switch. On the sub-base is located a relay for operating the automatic device on the oil switch.

The next (9th) panel is to control the alternating-current side of the 325-kw motor-generator. It has upon it three 300-amp. ammeters, two 300-kw indicating wattmeters, one 175-volt voltmeter, a synchronizing receptacle, a 100-amp., single-throw, single-pole exciter switch, a 2,500-volt, 300-amp., three-pole automatic oil switch and one relay for the automatic oil switch. The compensators for both the 300-kw synchronous motor and 100-kw synchronous motor are located under the switchboard platform.

Next to this is the panel for operating the 100-kw synchronous motor. This has a 100-amp. ammeter, to show the primary current, one 35-amp. ammeter to show the exciting current, one 2,500-volt, 300-amp., three-pole automatic oil switch with relay. There are two panels for the exciter and each panel has an ammeter. On one is a voltmeter, which can be used on either machine with the aid of a voltmeter plug. Each exciter has two three-pole, single-throw switches. The other generator panels are for direct-current apparatus and contain the usual switches and instruments customary on 500-volt railway and power generator panels.

Recording wattmeters are placed on all outgoing light, power and railway circuits except the series arc circuits; the power supplied to the meters driving the series arc machines is measured, so that really the entire output is measured by recording wattmeters.

In connection with this plant there is a very complete system for unloading, conveying and storing coal. There is a Gantry crane operating on tracks running parallel with the dock front and spanning the coal yard.

The surface equipment for hauling coal from the coal storage to the boiler room consists of a system of industrial railway and charging cars, designed and constructed by the Russell Wheel & Foundry Company, of Detroit, Mich. The outdoor tracks are laid 18 ft. 6 in. between centers, covering the coal-storage space between the legs of the Gantry crane, and connect by means of curves and switches to a track leading to the boiler room. All cars must pass over a two-ton capacity track scale of special design.

The outer tracks, 20½ in. gauge, are made up of 16-pound rail, spiked to oak ties. The curves are of special design, 12 ft. radius to center of track, and made of cast steel. The tracks, curves and switches within the boiler room are of cast iron, cast in plates, and arranged so that the full charging cars may stand in front of the boilers and the empties may be passed around them.

The charging cars are of malleable iron and steel, of 1½ tons capacity. The running gears are so designed that the cars run around the curves of 12 ft. radius easily. The doors of the cars when lowered form an apron from which the coal is shoveled into the boilers. The ashes are removed, by means of a 12-cu. ft. tip car, to vacant property across the street.

The Gantry crane which operates on the track along the dock front is designed to unload coal from the holds of vessels and automatically convey it to a coal storage pile on the dock, the coal pile being 100 ft. wide by 250 ft. long and 20 ft. high. To accomplish this the crane spans the coal dock, running on tracks on the ground level, 110 ft. center to center, and the bottom chord of the bridge is 27 ft. clear of the dock level, giving ample clearance for a coal bucket over the coal pile.

The crane consists of a bridge with a moveable apron, a back pier that supports the end of the bridge away from the water, and a front pier carrying the hoisting and traveling mechanisms and the operator's house. Both piers are carried on wheels and a power-driven squaring shaft running across the bridge is connected by means of sprocket chains to the driving wheels on each pier.

The bridge and its hinged extension, the 35-ft. apron, carry a runway for a trolley, and supported from the trolley by means of the hoist rope is the hoist block to which is attached the coal bucket. On the front pier there is a platform upon which stands the operator's house, where controllers and levers are placed so that one operator can control all motion of hoisting, lowering, trolley traveling and bridge traveling. The hoisting and bridge traveling mechanism with its motor is also located in the operator's house. The trolley traveling mechanism with its motor is located on top of the pier, but its controller, as before stated, is below in the house. On the platform a scale is placed where the bucket can be landed so that each bucket of coal can be weighed before being stocked, if so desired. The operator's stand is so located that a clear view may be obtained of the vessel on the one hand and the stock pile on the other.

When the crane has been placed opposite a hatch from which coal is to be unloaded, the apron is lowered, giving a 35-ft. extension over the vessel's deck. The trolley carrying a clam shell bucket is run out over the hatch and the bucket is lowered into the coal. The attendant in the hold pulls the lever and gives the operator the signal. The hoist block rises, pulling on the closing chain until the bucket jaws close together. Then the hoist block lowers and rises again, carrying with it the closed clam shell and 2,000 pounds of coal. When the trolley is reached the operator throws in his trolley traveling mechanism, running the trolley with its load back along the bridge to the dumping point, where the bucket is opened as it passes under the dumping trigger, the coal falling to the stock pile below.

About 70 per cent. of the coal in the vessel can be removed with the clam shell bucket, but the remainder must be shoveled into the ordinary coal buckets. Three of these buckets are furnished with the machine, and are dumped by the same triggers that operate the clam shell.

In rehandling the coal from the stock pile to the cars that carry it to the boiler house, the crane is used in connection with a moveable bin. This bin stands on a track of wide gauge and has a capacity of 40 tons, being sufficient to supply the power house needs for twenty-four hours. The small coal cars run under it on a narrow-gauge track and are filled by opening a valve in the bottom. In the morning the bin is filled from the stock pile with the clam shell.

In unloading the vessels the motions of hoisting and trolley traveling occur every time a bucketful of coal is handled, while movements of the entire crane are necessary only when the crane moves from a hatch that it has just emptied to a full hatch. For this reason the machine has been given a hoisting speed of 100 ft. per minute, a trolley travel speed of 600 ft. per minute, and a crane travel of only 60 ft. per minute. These speeds will enable a skilful operator to handle the buckets at the rate of one trip per minute from the hold of the vessel to the stock pile and return, and while the clam shell is in operation, only one man should be necessary in the hold of the vessel. When hand shoveling is resorted to the machine will keep three buckets in continuous operation, two of which will always be in the hold of the vessel at the disposal of the shoveling gangs. On the machine itself one man controls all the motions of the crane.

The coal yard being 250 ft. long, it is not deemed advisable to rehandle the coal into a stationary bin, as this would make the operation a slow one, and as traveling the whole crane 250 ft. to deposit one ton of coal in the bin would be too much like sending an elephant to pick up a peanut, the movable bin has, therefore, been adopted. The first work in rehandling consists in clearing up that portion of the yard nearest the river, the clam shell being used and the crane making side travels of not to exceed 30 ft. with each load. After this the crane can remain in position with the movable bin under the end near the river, and all movements can be confined to trolley traveling and hoisting, the crane being moved only when a whole section of the yard has been cleaned up. One hour's work with one man in the operator's house and one man on the coal pile

It will be readily seen that it would be dangerous to attempt to run a crane of this span with tracks separated by a great coal pile and nothing provided to inspire perfect alignment unless there were some provisions for automatic adjustment. If the crane were rigidly constructed, 1½ in. misalignment of the tracks would bring the flanges of the wheels against the tracks and strain the structure. Furthermore, when the crane is moved along the tracks, if one end started a little ahead of the other owing to the slipping of a wheel or the necessary lost motion in the driving chains leading from the squaring shaft to the wheels, the crane structure would again become strained and the wheel flanges bound on the tracks.

To overcome these difficulties, the crane has been built in three separate pieces; the front pier, the back pier and the bridge. At the front pier the bridge is suspended in such a manner as to allow it a limited motion in a horizontal plane about a king pin. At the back pier the bridge is allowed universal motion, this pier simply supporting the load. This form of construction permits the crane to automatically adjust itself to any reasonable track variations, and one pier can, if necessary, travel 4 ft. in advance of the other before the wheel flanges will bind. The crane is designed and built by Whitehead & Kales Iron Works, of Detroit, Mich., and is unique in being flexibly constructed and yet having but two tracks. Fig. 9 shows the arrangement of wires leaving the station.

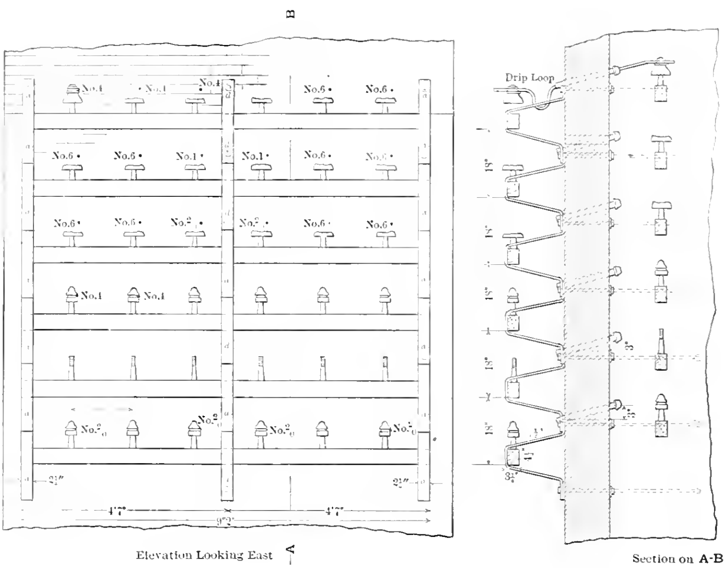

FIG. 9.—LINE DETAIL.

An Important Trolley System for New Jersey.

New Jersey is the center just now of a great deal of important work in trolley extension, some of which has apparently a bearing upon other plans. Articles of incorporation for the New Jersey Short Line Railroad Company were filed last week at Trenton and deserves attention. The object of the company is to extend the electric line of the Trenton & New Brunswick Railroad Company from their present terminus at Milltown to Elizabeth. The company is a plan of the Public Service Corporation to shorten the route from Philadelphia to Jersey City by fourteen miles. It is rumored at Trenton that the line is part of the Gould system of railroads, which is trying to get to New York. The capital stock of the company is $3,000,000. The route is to cross the Raritan River, near Weston's Mills, and to go to Metuchen and Rahway and Elizabeth, where the line will connect with the present line of the Public Service Corporation.

The entire length of the road is to be fifteen and five-tenths miles, and the road is to be built in Middlesex and Union Counties. The terminus at Eliabeth will be near the western boundary of the city. The company was incorporated under the Railroad Act of 1903. The incorporators and the amount of capital subscribed as set forth in the articles of incorporation are as follows: Richard I. D. Ashbridge, of East Bowington, Pa., $19,500; Thomas S. Phillips, of Philadelphia, $19,500; Thomas B. Courley, George H. B. Martin, John H. Switzer, of Camden; Abraham A. Moyer and Thomas Heller, of Philadelphia, $200 each. The company paid to the State $37,000 as an incorporation fee.

The immediate intention of the road is to form a continuous trolley line from Philadelphia to New York, and cut off the time now lost by going from this city to Bound Brook and Plainfield to get to Newark. This road will shorten the trolley distance fourteen miles. An agreement has already been entered into between the promoters of the new company and the Public Service Corporation by which the cars of the Public Service Corporation will use the road as soon as it is built. The trolley excursion fare from Trenton to Newark is to be $1.50, and the single fare 80 cents.

Ohio Electric Light Association.

This association will hold its next annual convention at Sandusky, Ohio, on August 16, 17 and 18 next.

Booster Calculations.

By WM. A. DEL MAR.

THE booster is a generator placed in series with a conductor for the purpose of neutralizing the drop of potential in the latter. The e.m.f. of the generator is made to act in opposition to the drop in the line so as to neutralize it partially or entirely, thereby causing the combination to act as a conductor of lower resistance. If the e.m.f. of the generator were exactly equal and opposite to the drop of potential in the conductor, the two would neutralize one another, and the combination would act as a perfect conductor. It is in railway work that the booster has found its principal application. The powerful currents required in this service cause the potential of

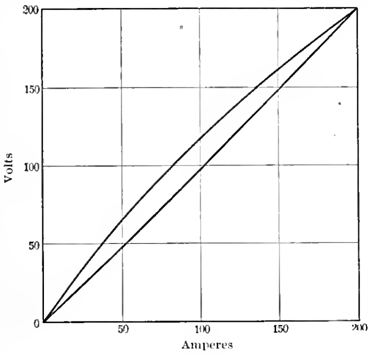

FIG. I.

feeders to fall very much at points distant from the generators. It may therefore occur that at some points the line voltage will be so low as to cause the lights to dim and the cars to run at less than their normal speed. This trouble might be remedied by the use of extra feeder cables, but it often occurs in practice that the cost of these is so enormous as to be quite prohibitive. It is in such cases that the booster finds it application. A small amount of cable and a booster will reduce the drop of potential as effectually as a system of cables that would cost perhaps several times as much.

The booster is probably most useful in reducing the potential drop

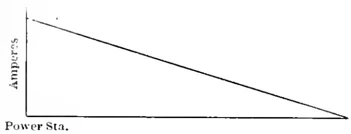

FIG. 2.

in grounded return feeders. Here a drop of potential that would not appreciably affect the operation of the car lights and motors, might be the cause of serious electrolytic damage to underground pipes and cable sheaths. This is a subject that is scarcely given the consideration it deserves, but it is gradually forcing the attention of railroad officials who have to decide whether it is better to install efficient return feeder systems or to run the chances of having to pay for the destruction of cable sheaths and pipes.

The booster is usually a series wound generator having a fairly straight characteristic, in order that its voltage may be approximately proportional to the load it carries. The characteristic of such a generator is shown in Fig. 1, with a straight line next to it for comparison. The deviation from the straight line is principally affected by the saturation of the magnetic circuit so that the smaller the allowable deviation the more expensive the generator. As, however, the curve is always above the straight line at partial loads, the booster will act better with partial than with the full load. Hence if calculations be made for the full load the booster will more than do its work at partial loads. For this reason all booster calculations should be made for full-load current. A booster may be either steam-driven if in a power station or motor-driven if in a sub-station. The method of connecting up a booster to a feeder system as well as other details, will be considered later.

In railway feeder work it is usual to assume the load to be uniformly distributed along the line, so that going towards the power station the current in the feeders gradually increases. The current flowing in the feeders to the bus-bars will thus be represented by a straight line diagram, as shown in Fig. 2. This occurs where all the feeders are connected together so as virtually to form one conductor. When, however, a booster cable is connected to the feeders

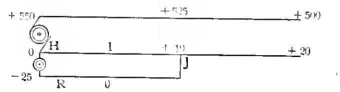

FIG. 3.

at a certain point, as shown in Fig. 3, the booster cable being insulated from the other feeders, except at that point, the current will take a course different from that shown in Fig. 2. In this case some of the current will be drawn from the line into the booster cables and the current diagram will take one of the forms shown in Fig. 4.

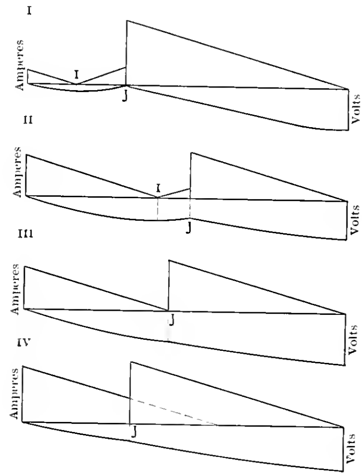

FIG. 4.

There are four typical cases to be considered, differing in the various possible distributions of current and potential Case I shows a booster which entirely neutralizes the drop in the booster cables and reduces the point of connection, J, to the same potential as the bus-bar. In this case current is drawn into the booster cables from both sides of the point of connection, the current dividing at a point I from which the resistance to the bus equals the resistance to the point J. In Case II, the booster only partially neutralizes the drop in its cables, but nevertheless draws current from both sides of the point of connection. Case III shows a booster drawing current only from beyond the point of connection, the whole of the current on the other side returning to the bus by the line feeders. In Case IV, the booster only draws part of the current from beyond the point of connection, the remainder returning to the bus through the line feeders with the current from between the station and that point.

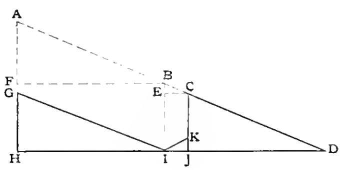

FIG. 5.

These four cases are represented with their respective curves of current and drop in Fig. 3. A fifth case might be added to these, which placed in its proper position should precede Case I. It is only useful when the permissible drop is extremely small. In this case the point of connection, I, is maintained at a lower potential than the negative bus itself.

The first two cases resemble one another in their current diagrams, and may, to a certain extent, be considered together. The distribution of current in the feeder system, *H I J D* (Fig. 5), is given by *G I K C D*. The current with no booster is indicated by the broken line, *A B C D*. When, however, a booster cable is connected at *I*, it will, in the case under consideration, take all of the current from beyond it and some of the current from between it and the power station. How to determine the position of the point *I* where the current divides will be seen later. It suffices to say here that *I* and *J* being known, the current "curve" may be drawn by making $IJK = CEB$ and $IHG = BFA$. A curve of drop for Case II is shown

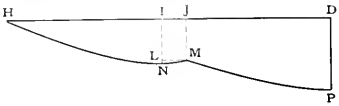

FIG. 6.

in Fig. 6, in which the letters *H I J D* refer to the same points as in Fig. 5. In this diagram the drop *I N* is due to the current *H G I*; *L N* to the current *I J K*; *M P* to the current *D J C*, and *J M* to the current in the booster cable. The drop *M P* is given for every

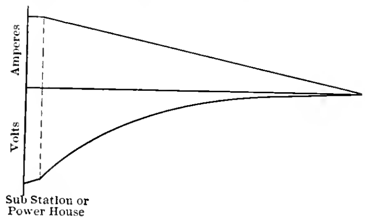

FIG. 7.

point *J*, in Fig. 7. The method of obtaining this curve is indicated in Fig. 8, in which the drop curve without booster is given by the curve *R*, and the ordinates, *R S*, are the same as the ordinates of the volt curve in Fig. 7. The drop *H N* is given in Fig. *I*; currents originating at various points, I_1, I_2, I_3, etc., and increasing the same number of amperes per foot, are assumed, and the drop from *H* to

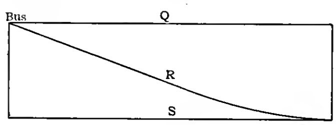

FIG. 8.

I_1, I_2, I_3, etc., are calculated and plotted as the ordinates of the curve. Thus the ordinate $I_4\ T_4$ is the drop between *H* and I_4, with a current "curve" $I_4\ G_4$.

A simple way to obtain the curve shown in Fig. 9 is worthy of notice.

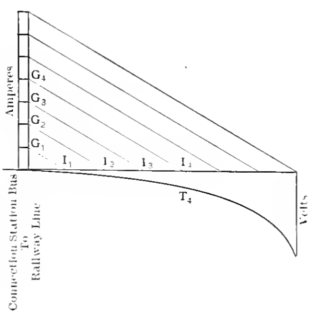

FIG. 9.

Fig. 10 gives two curves of potential drop produced respectively by currents originating at *D* and *S*. It should be observed that the difference between the two currents, which is indicated by *U V*, is equal to *H T*, and that *H U* is equal to *T V*. The drop, $S V_2$, may be regarded as the sum of the drops produced by the tapering current *T V*, and the uniform current *H T*. Now $HU = TV$, and SV_1 is the drop produced by *H U*, so that $SV_2 = SV_1 + HT \times$ (resistance of *H S*) or $SV_1 = SV_2 - HT$ (resistance of *H S*).

When the curves of Figs. 7 and 9 are plotted for the line in question, it will be easy to make the calculations for a booster to give any desired drop of potential. As stated above, these curves should be constructed for the maximum current that will last for any appreciable length of time, and liberal provision should be made for an increase of load.

It is necessary to establish a formula which will give the voltage required for the booster. In any closed circuit the sum of the differences of potential taken around the whole circuit is zero. Hence, referring to Fig. 3, consider the variations of potential around the closed circuit *R J I H*, taking the drop towards the bus as positive and away from it as negative, so that if the booster voltage be represented by *V*, the following equation is obtained:

Drop in IH + drop in RJ — drop in $IJ - V = O$.

From this it follows that—

V = drop in RJ + drop in IH — drop in IJ.

The drops in *IH* and *IJ* are given respectively in Fig. 6, as *IN* and *LN*, so that the above formula may be written, V = drop in booster cables $+ IN - LN$. Now, in Fig. 6, $JM = DP - MP$ and $LN = IN - JM$, so that $LN = IN - DP + MP$, and, therefore, V = drop in booster cables $+ DP - MP$. From the two last formulas

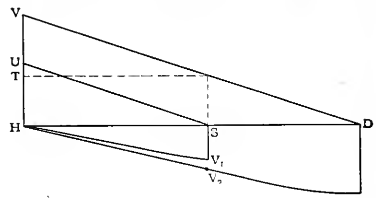

FIG. 10.

two important conclusions may be drawn, namely, that the points *I* and *J* must be so related that $LN = IN + MP - DP$, and that in order to get a total drop of *DP* with the booster cables connected at *J*, the booster voltage must be equal to the sum of the drop in the booster cables and the total drop *DP* in the line feeders, less the drop *MP*.

Referring to Figs. 6 and 9, it should be observed that if a certain drop *DP* be required, the point *I* cannot be farther away from the bus than the point in Fig. 9, having the ordinate equal to *DP*, and the

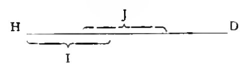

FIG. 11.

most distant location for the point *J* is midway (along the resistance —not along the length) between *I* and *D* when *I* is at its most distant position. Referring now to Figs. 6 and 7, it will be observed that *J* cannot be nearer to the bus than the point in Fig. 7, having the ordinate equal to *DP*. As *I* can be as near to the station as is desired, the possible positions of the points *I* and *J* are limited, as indicated in Fig. 11.

It is now necessary to find the most economical point *I* and its corresponding point *J* by trial. In order to find the point *J* for any point *I*, a table should be constructed on the plan given below:

1	2	3	4	5	6
Length *H J* feet.	Volts *L N* =IN (MP-DP)	Length *I J* feet	Amperes *J K*	Resistance *I J* ohms	Drop in *I J* = ½ *J K* x resist of *I J*

Different values of *H J* are chosen between the limits given in Fig.

11, and $I\,J$ being known, column 2 can be constructed. The current $J\,K$ (column 4) is the product of the amperes per foot, and the length $I\,J$ in feet. The correct value of HJ is that which causes the quantities in columns 2 and 6 to be equal. A number of points I should be tried, and their corresponding points J found according to the above directions. It is obviously wrong to choose $H\,J$ so that $IN < (MP - OP)$ as IN must have the same algebraic sign as MP and DP, and DP cannot be less than MP. Hence it is useless to assume $HJ < HI$. This narrows the limits between which to try HJ, so that very often the correct point J for a given point I will be found after three or four trials.

For any particular value of I, the cost of the booster installation is calculated in the following way. Knowing the points I and J, the currents $J\,C$ and $J\,K$ (Fig. 5) are known. The current carried by the booster cables is the sum of these. The size of cable and their number are determined by the current they carry so that their resistance and the drop in them can be calculated. The voltage of the booster is given by the formula $V =$ drop in booster cables $+ DP - MP$ (Fig. 6). From the current and voltage the kilowatts of the booster may be obtained. The cost of boosters is taken at a certain number of dollars (say, $75) per kilowatt, and the cost of the switchboard panel and wiring (say, $500 to $1,500) added to this.

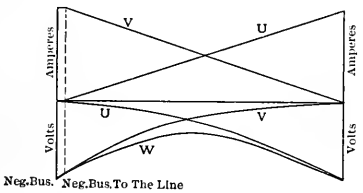

FIG. 12.

The value thus obtained added to the cost of the cable, including installation, gives the total cost of the booster system.

It is now necessary to return to some general considerations of the four cases illustrated in Fig. 4. The third case will be considered first as it is the simplest. In this case there are two completed drop curves, each of which becomes horizontal where the current is zero. Each of these curves may be derived from those given in Figs. 7 and 9. The drop from the bus to J is given by Fig. 9, and that from J to the end of the line by Fig. 7. The total drop from the bus to the end of the line, whatever the position of J may be, is the sum of the ordinates of these two curves. Fig. 12 gives the curves of Figs. 7 and 9, and one obtained by adding their ordinates. This curve W shows that Case III is not always applicable, as it fails for drops less than the minimum ordinate. For any drop greater than this minimum, there are two possible positions for the point J. An example of this is shown in Fig. 13, where the broken lines represent one case

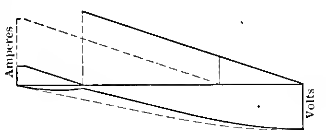

FIG. 13.

and the full lines another, each giving the same drop of potential. In Case IV, for a given position of J, the drop is greater than in Case III, because the current on the line is greater. Hence a smaller drop than is shown by the curve W (Fig. 12) is not attainable by this case.

It is now convenient to consider Case II in connection with the curve W. For a given position of J, the total drop will be a maximum when J and I are coincident, so that Case III is the limiting condition of Case II. Hence the total drop cannot exceed the ordinates of the curve W. Referring to Fig. 14, it will be seen that in order to get any given drop HQ, the point J must be chosen to the right of where QE intersects the curve V, for otherwise the drop to the end will be greater than HQ. This combined with the condition that the point J cannot be where the line QE is below the curve W, shows that J must be between A and B, or between C and E. If J be chosen in AB, the booster will have to carry a very large current, but must generate but a small voltage. This is not a practical machine, so that J will generally be in CE. When HQ is less than the minimum of the W curve, the possible positions of the point of connection, J, lie between A and E. Furthermore, the point I cannot be to the right of where QE intersects the curve U, or the drop between J and the power station will be greater than HQ. These considerations should serve to simplify the calculations by reducing the number of trials for the correct positions of I and J.

From these considerations it appears that if the desired drop be

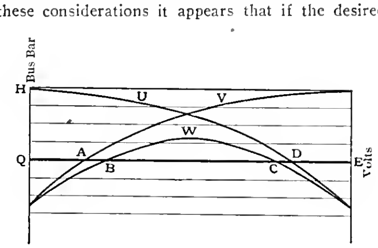

FIG. 14.

below a certain amount, Cases III and IV may be left out of consideration, and that the best way by Cases I and II must be found by trial. There are two ways of getting a given drop by Case I. One is to get the maximum permissible drop between H and J, and the other to get it between J and D.

When the cost for a number of positions of I has been calculated in the way described, a curve like that shown in Fig. 15 may be plotted, in which the total cost of the system for different positions of I or J is given. The point where the curve reaches a minimum indicates the most economical booster scheme that will give the required drop.

The apparatus required for a "negative booster" panel is shown

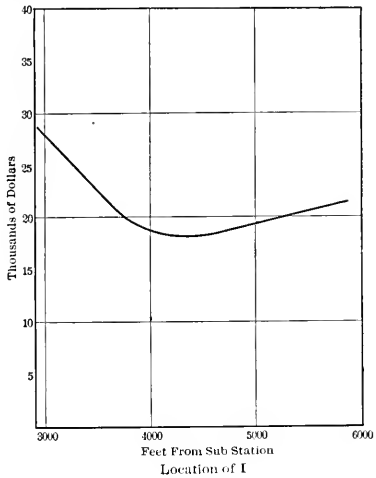

FIG. 15.

in the diagram, Fig. 16, where the booster is represented as a series dynamo driven by a three-phase induction motor. In series with this generator are a circuit breaker and switch. This switch has a single pole, but double throw, so that at times of light load the booster cables may be connected directly to the bus without requiring the use of the booster itself. In the case of a booster for the positive or non-grounded feeders, a single-pole single-throw switch is required between the bus and booster.

The following guarantees should be required of a booster. After a run of twenty-four hours at full rated amperes and volts, the temperature of no part of the machine should exceed 40 degs. C. by thermometer, above the surrounding air, provided this latter is not over 25 degs. C. The booster must also be capable of giving 25 per cent overload in amperes or 50 per cent overload in kilowatts for one-half hour, and must be able to stand a momentary overload of 100 per cent in kilowatts. The voltage regulation depends on the amount of iron in the field magnets, so that the best regulation is only attainable in expensive machines. The actual voltage at any load should not differ from the voltage given by the straight line characteristic (Fig. 1), by more than 20 per cent.

In order to calculate the current that will flow through the booster cables when there is no booster, one may proceed in the following way: Let I be the total current taken by the section of line under consideration; i, the current in the booster cables; R, the resistance

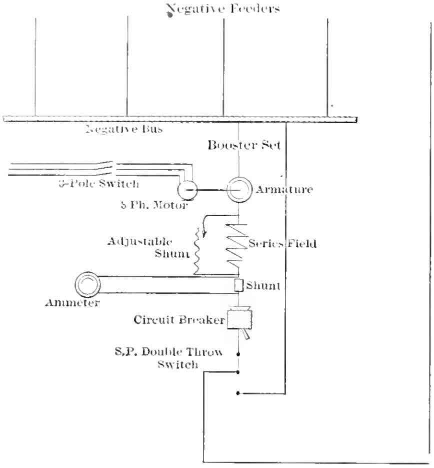

FIG. 16.

of the feeders between H and J; and r the resistance of the booster cables. Then the drop in the feeders between H and J is $R \times \frac{1}{2} (I - i)$, and the drop in the booster cables between the same points is $r - i$. These two must be equal, so that

$$ri = \tfrac{1}{2} R (I - i)$$

$$\therefore i = \frac{RI}{2r \times R}$$

This is an important calculation, as it enables the influence of the booster cables on the drop to be calculated.

In any feeder system whether or not boosters are employed, the value of the energy lost is an important item. The power lost in the line is equal to the product of the amperes per foot, and the area of

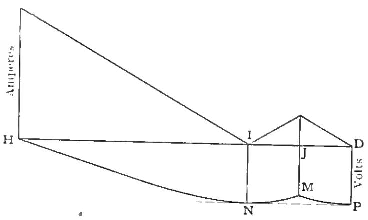

FIG. 17.—PARTICULAR CONDITION IN CASE II, THAT IS OFTEN THE MOST ECONOMICAL, NAMELY, WHEN IN = DP.

the drop curve expressed in volt feet, so that the number of watts lost in either the positive or negative system can be easily computed with the aid of a planimeter. When, however, there is a booster, the watts lost in the booster cables must be added. This may be calculated for full load and the kilowatt-hours per day obtained on this basis. In order to get the true kilowatt-hours per day this should be multiplied by the load factor. This latter quantity is obtained in the following way. As the power lost in a conductor is proportional to the square of the current in it, if the current be variable, the mean power lost will be proportional to the mean of the squares of the currents. The load factor mentioned above is the ratio of the mean of the currents squared to the maximum current squared. The mean of the currents squared may be found by squaring the ordinates of a load diagram and taking their mean.

In comparing the costs of feeder and booster systems, the value of the energy lost per annum may be capitalized and added to the initial expenditure.

When a line is supplied with current from two power houses or sub-stations, the feeder systems from these two must have about equal resistance, or one of the stations will "pull" a greater load than the

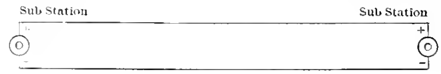

FIG. 18.

other. Hence putting a booster in one station will cause that station to carry a greater load unless the other be similarly equipped. This will not occur if the positive feeders are broken at the central point, as shown in Fig. 18. Hence there may be the choice of two booster sets against one booster set, and the cable, etc., for the break. Other problems are likely to arise in connection with booster calculations, but the foregoing considerations should be sufficient for most purposes.

High Tension Discussion in Chicago.

The Chicago branch of the American Institute of Electrical Engineers held a meeting on March 29 to discuss the general subject of high-tension work inside the station, high-tension being defined by the chairman, P. Junkersfeld, to be 5,000 volts and over.

The Institute paper of Mr. E. W. Rice, Jr., on the relative fire risk of oil and air-blast transformers was abstracted by James Lyman.

W. A. Blanck thought 30,000 volts was the upper limit of air-cooled transformers, and the lower limit for water-cooled oil transformers. Mr. Junkersfeld mentioned the awkwardness of making the connections in an oil-cooled transformer of 5,000 to 12,000 volts and large amperage. He also stated that the air-blast type is usually the cheapest, the difference depending on the temperature rise allowed. Mr. Thomas had an insulated water and oil system frozen up last winter. Mr. D. W. Roper mentioned an oil fire caused by the heat from hysteresis. Mr. G. H. Lukes thought the air diaphragm as a fire preventive both good and inexpensive. He suggested a tank of carbon dioxide on top, to smother the blaze by injection into the air duct.

The paper on the use of group switches in large plants by Mr. L. B. Stillwell was presented by Mr. F. Woodmansee. It being impracticable to discuss this in the abstract, concrete examples were suggested by various members, with the conclusion that local operating conditions entirely determine the question of installing such switches. The operation of these group switches with feeder switches under various combinations of time limits was brought up, and Mr. W. G. Carlton stated that a ground or short-circuit would shut down everything on that bus-bar before the time limit would operate if such device were used.

Oil switches for high voltages were introduced by an abstract of Mr. E. M. Hewlett's paper, and provoked a free discussion of the form of cover best adapted for oil switch boxes. Mr. Junkersfeld advocated an iron lid containing a glass panel, to reveal what the condition of the switch is after opening the switch on a short-circuit. A defective switch, if not detected before closing under such circumstances, would cause a much more serious shut-down. Mr. Sessions considered the glass unnecessary, and would so mount the iron door as to allow two inches free air space under its edges, providing the iron door with a counterweight and trip, so that it could be quickly opened.

Long Telephone Circuit.

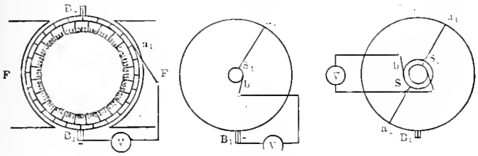
The New York Central Railroad system will soon own what it is claimed will be the longest private telephone direct wire in the world. It will be a No. 8 copper wire along the tracks of the Central all the way to Chicago. It will touch every important city on the lines of the system, and will, therefore, extend a distance exceeding 1,000 miles. West of Buffalo the wire will follow the tracks of the Lake Shore Railroad, and east of that city it will run along the New York Central tracks, coming into Weehawken along the West Shore line. The wire will cross the river in cable and will end in the Grand Central Station.

Synchronous Converters.

BY F. G. BAUM.

IT would be presumptuous for the writer to try to improve on the very excellent theory of the synchronous converter given by Mr. C. P. Steinmetz, in his book, "Elements of Electrical Engineering." However, I find that students and engineers have considerable difficulty in understanding his theory without some explanations, and I have found that the following way of approaching the subject gives good results.

If we rotate a continuous-current armature (Fig. 1.) so that we get a difference of potential between the brushes, and then connect a voltmeter to one brush and move the other terminal connected to the voltmeter around the commutator so as to get the potential of



FIGS. 1, 3 AND 4.—SINGLE-PHASE CONVERTER.

the commutator bars as they pass different parts of the field, we obtain a curve like that shown by the full line in Fig. 2.

Instead of drawing the commutator bars and winding as in Fig. 1, we shall represent the winding by the circular line as in Fig. 3.

If we connect one point of the armature winding a_1, Fig. 3, to a slide ring and connect an instrument, V, such as the oscillograph, which will measure instantaneous values of potential between the slide rings and one brush, it is evident that the curve traced will be the same as that shown in Fig. 2. That is, the potential of the slide

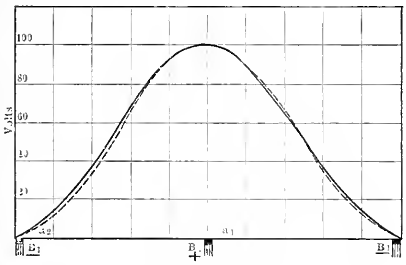


FIG. 2.—DISTRIBUTION OF POTENTIAL AROUND COMMUTATOR.

ring, counting the potential of the negative brush as zero, is measured by the ordinates in Fig. 2.

Suppose now we connect a second point, diametrically opposite to the first, to a second slide ring, S_2, Fig. 4, and connect our instruments for measuring the instantaneous potential between the two slide rings as shown. It is evident now that the difference in potential between the slide rings is the same as the difference in potential between the points a_1 and a_2, Fig. 2. But the difference in potential between a_1 and a_2 may be obtained from the curve by subtracting ordinate a_2 from a_1. In the position shown a_1 is at a higher potential than a_2. An instant before the position shown a_1 was under brush B_2, and a_2 was under brush B_1, in which position there was maximum voltage between the slide rings. This maximum voltage is, of course, equal to the potential between the brushes of the direct-current machine. As rotation goes on a_1 decreases in potential and a_2 increases, until the points are opposite the center of the pole faces, when the difference in potential becomes zero. Then a_2 increases, and a_1 decreases, until a_2 is under B_2 and a_1 under B_1, when we again have maximum voltage but the reverse of before. That is, for each revolution of the armature the potential difference between the slide rings passes through a cycle as shown in Fig. 5.

We, therefore, obtain an alternating e.m.f wave from a direct-current machine, by connecting two diametrically opposite points to two slide rings. (In a two-pole machine we connect diametrically opposite points to the slide rings; in a multipolar machine we must connect one point opposite each N pole to one ring and one point opposite each S pole to the other) to two slide rings.

We may supply direct-current to such a machine driving it as a direct-current motor, and take off alternating-current. Or we may supply alternating-current driving it as an alternating-current motor and take off direct-current. Such a machine is called a rotary converter, and is most generally used for converting from alternating to direct current. We may also drive the machine mechanically and take off alternating and direct current simultaneously.

FREQUENCY OF ALTERNATING CURRENT.

It is evident from the above explanation that the frequency of the alternating potential in a two-pole machine is equal to the revolutions per second of the armature. For an alternating current having frequency of 60 cycles the armature would have to make 60 revolutions per second, or 3,600 r.p.m. This speed is too high even for small machines, and therefore rotary converters are made multipolar. Even then it is a difficult matter to build rotary converters of large capacity

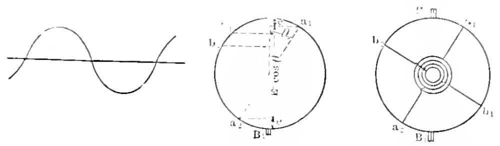

FIG. 5.—SINE WAVE OF PRESSURE. FIGS. 6 AND 7.—TWO-PHASE CONVERTER.

for as high a frequency as 60 cycles. For, as we increase the number of poles to reduce the speed, the diameter of the commutator must be increased to keep the voltage between the commutator bars within safe limits. This is a difficult matter, and, except for small capacities, rotary converters are generally not recommended for a greater frequency than 30 or 40.

If, instead of bringing taps from a_1, a_2, Fig. 4, to the collector rings, it were possible to rotate the alternating-current brushes directly on the commutator we could obtain an e.m.f of any frequency from any direct-current machine, no matter what its speed, by merely revolving the brushes at the frequency desired. To carry this out practically would mean building a commutator outside the bearing of the machine and then rotate the brushes by a small synchronous motor. It is very probable that the difficulties are insurmountable in a practical way, especially the sparking which would occur at the brushes.

WAVE FORM AND RATIO OF CONVERSION.

It is generally considered best, for general purposes, that the curve shown in Fig. 5 should be a sine wave. Now, what is the necessary condition that we get a sign wave of e.m.f. from the converter?

The maximum e.m.f. obtained is when a_1 and a_2 are directly under the direct-current brushes. Suppose the diameter of the circle in Fig. 6 represents this maximum potential, E. Then when the armature has rotated through the angle, Θ, the potential between the slide rings should be $E \cos \Theta$, which is represented by the projection of $a_1 a_2$ on the vertical diameter. This means that the potential difference between brush B_1 and a_2 must be represented by the projection of the arc of the circle from B_1 up to a_2 on the vertical diameter, and represented by e. Similarly, the potential between B_2 and a_1 must be e. This means, further, that the potential between any two points of the armature $b_1 b_2$ is represented by the projection of the length of the arc on the vertical diameter. The equation of the curve in Fig. 2 is

$$\text{ordinate} = \frac{E + E \cos \Theta}{2},$$

Θ being measured from the brush B_2 as shown.

In Fig. 2 the heavy line represents the curve obtained in an ordinary direct-current machine not built for converter work. The dotted line shows the curve as it should be to give a true sine wave. As we see, the curves differ very little, and it is generally found that any armature completely overwound gives a close approximation to a sine wave, with the ordinary design of pole pieces. However we find occasionally machines with distorted waves, and it is difficult to operate these as synchronous converters, owing to "hunting," caused by a difference in wave between generator and converter.

With two diametrically opposite points we obtain practically a sine wave from any direct-current machine; but it is easy to see that if we connect two points very near together to two slide rings we will not obtain a sine wave, unless the potential of distribution around the commutator is as shown by the dotted line in Fig. 2. With two points very close together we would obtain from an ordinary direct-current machine the curve of magnetic distribution, since owing to the small and equal air gap the angularity of the coil may be neglected. We will therefore not get the same e.m.f. curve from a three-phase converter as from a single-phase, because for the three-phase the armature is tapped every 120° instead of 180°, as in the single-phase or two-phase.

We may obtain a two-phase converter by tapping the armature as in Fig. 7, the phase b_1b_2 being taken midway between a_1a_2. A three-phase converter may be obtained by tapping the armature as in Fig. 8.

RATIO OF ELECTROMOTIVE FORCES.

Since in a single-phase or two-phase converter the maximum alter-

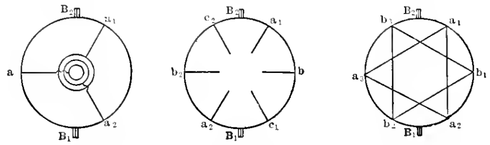

FIG. 8.—THREE-PHASE CONVERTER. FIG. 9.—SIX-PHASE DIAMETRICAL CONNECTION. FIG. 10.—SIX-PHASE DELTA.

nating-current potential is equal to the direct-current brush potential, the effective value of the alternating e.m.f., assuming a sine wave, is

$$E_1 = E/\sqrt{2} = .707\ E. \qquad (1)$$

In a three-phase converter the maximum potential between a_1 and a_2 would be when the arc, $a_1\,a_2$, has a maximum projection on the diameter, B_1B_2. This length will be the length of the cord a_1a_2. This may be easily found as follows: The length of the radius of the circle, Oa_1, is $E/2$, and the length of the cord, a_1a_2, is therefore $\dfrac{E\sqrt{3}}{2}$. The effective value of the potential is

$$E_1 = \frac{E\sqrt{3}}{2\sqrt{2}} = .615\ E. \qquad (2)$$

The only other converter used to any practical extent is the six-phase converter. This may be obtained by tapping the armature at six points as shown in Fig. 9. Evidently we may connect one phase across the diameter as shown in Fig. 9 or across 120° as in Fig. 10. The first is the diametrical connection which has the advantage of a higher voltage between slide rings over the "delta" ( ) shown in Fig. 10.

FIG. 10. SIX-PHASE, DELTA CONNECTION.

If there are n collector rings the voltage between adjacent collector rings will be

$$E_1 = \frac{E \sin \pi/n}{\sqrt{2}}, \qquad (3)$$

as may be easily proved.

RATIO OF CURRENTS.

Consider again the converter as transforming from direct to alternating. Suppose I amperes direct current is consumed by the converter, what will be the output in alternating current? Take first a single-phase converter. Since for a complete cycle the direct-current input must be equal to the alternating output, neglecting losses, we must have, assuming the alternating current to be in phase with the pressure,

$$E\,I = E_1I_1 \qquad (4)$$

in which E_1 and I_1 are the effective values of alternating pressure and current. But we have $E_1 = E/\sqrt{2}$; substituting above we obtain

$$I_1 = I\sqrt{2}$$

That is, the effective value of the alternating current is the $\sqrt{2}$ times the direct current. Now the maximum value of the alternating current is $\sqrt{2}$ times the effective, and hence the maximum value of alternating current

$$I_1\ max = 2I \qquad (5)$$

Hence, in a single-phase converter the maximum value of alternating current is twice the direct current. At the instant then when the alternating current is a maximum, that is, when points a_1a_2 pass under the direct-current brushes, twice as much power is given out on the alternating side as comes in on the direct. When, on the other hand, the alternating current is zero, power is being taken from the direct-current mains at the same constant rate as before.

Referring to Fig. 6, when a_1a_2 are in the position shown the alternating-current pressure is $E \cos \Theta$, and if the current is in phase with the pressure, its value is $2I \cos \Theta$. The instantaneous power going out on the alternating side then $2\,E\,I \cos^2 \Theta$. The instantaneous direct-current power taken by the armature is $E\,I$. The difference between these must be the power given to or taken from the armature.

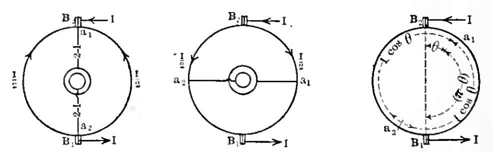
$$\text{Power given to armature} = 2E\,I \cos^2\Theta - E\,I$$
$$= E\,I\,(2 \cos^2 \Theta - 1) = E\,I \cos 2\Theta \qquad (6)$$

In a single-phase converter, therefore, when a_1a_2 pass under the brushes, a direct current, I, flows to the converter but an alternating current, $2I$, flows to the collector ring (Fig. 11). We may regard the direct current, I, as flowing direct from the direct-current mains to the alternating slide rings without going into the armature. The source of the other current, I, necessary to make up the difference between the alternating and the direct-current is, in this position, the armature, the inertia of the armature supplying the power, $E\,I$. When a_1a_2 have moved through 90 degrees to the position shown in Fig. 12 the alternating current is zero, but the direct current is still I. The direct current, I, flows then from brush to brush, giving back the power, $E\,I$, to the armature rotating mass. In a single-phase converter then the armature acts alternately as a motor and as a generator twice per cycle. As we shall see, because of this fact the single-phase converter does not commutate as well as the polyphase converter, in which the flow of power to and from the converter is at every instant the same, neglecting "hunting" and losses.

In a two-phase converter the power, $E\,I$, is flowing to the armature from the direct-current mains. The outgoing energy on the alternating side for a complete cycle must equal the incoming energy for the same time. Since we have two phases we have

$$E\,I = 2E_1I_1 \qquad (7)$$
$$\text{But } E_1 = E/\sqrt{2}$$
$$\text{Therefore } I_1 = I/\sqrt{2} \text{ or}$$
$$I_1\ max = I \qquad (8)$$

That is, the maximum value of the alternating current is equal to the direct current. Here we see that in a two-phase converter when a_1a_2 are directly under the brushes all the incoming direct current flows



FIGS. 11, 12 AND 13.—RATIO OF CURRENTS.

directly to the alternating slide ring, and there is no current in the armature (this assumes no losses). When b_1b_2 are on the brushes the same thing will occur in the direct-current passing direct to the slide ring without entering the armature.

We can easily see from the above that there will be less heating in a two-phase converter than a single-phase, because four times per revolution the armature current is zero—that is, the direct current passes directly from the direct-current mains to the alternating-current circuit without going through the armature—and for a considerable time the armature current is nearly zero. In a six-phase converter, diametrically connected there will be no armature current six times per revolution. In a three-phase converter three times per revolution the current flows over only a part of the armature.

HEATING OF ROTARY CONVERTERS.

With the above as an introduction, to give some idea of what occurs, let us calculate in as simple a manner as possible the heating of a single-phase and a two-phase converter. First, consider a single-phase converter, Fig. 13. It is simpler here to consider the direct current flowing from brush to brush just as though it were a direct-current machine, a current, $I/2$, flowing down each side of the armature. The alternating current, $2I \cos \Theta$, flows from a_2 to a_1, $I \cos \Theta$ flowing over each half of the armature, as shown in Fig. 13. We need only consider the heating of one side of the armature from brush to brush, as the other side will be the same.

The actual value of the current in that part of the armature between B_2 and a_1 will be the sum of the alternating and direct current; that is, equal to $I/2 + I \cos \Theta$; and the current in that part of the armature between a_1 and b_1 will be the difference between the alternating and direct current, and hence, equal to $I/2 - I \cos \Theta$. The resistance between B_2 and a_1 is proportional to Θ, and the resistance between a_1 and B_1 is proportional to $(\pi - \Theta)$. The instantaneous heating in the position shown is therefore proportional to

Instantaneous heating $= (I/2 + I \cos \Theta)^2 \Theta + (I/2 - I \cos \Theta)^2 (\pi - \Theta)$.

$= (I/2)^2 [(1 + 2 \cos \Theta)^2 \Theta + (1 - 2 \cos \Theta)^2 (\pi - \Theta)]$

$= (I/2)^2 [\pi + 8 \Theta \cos \Theta + 4\pi \cos^2 \Theta - 4\pi \cos \Theta]$,

and the average heating is the average value of this between the limits of Θ and π.

Average heating

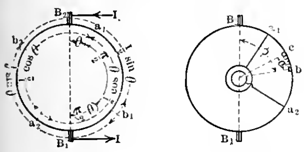
$$\frac{I}{\pi} (I/2)^2 \int_0^{\pi} (\pi + 8 \Theta \cos \Theta + 4 \pi \cos^2 \Theta - 4 \pi \cos \Theta)\, d\Theta$$

$$= \frac{(I/2)^2 (\pi^2 + 2\pi^2 - 16)}{\pi}$$

$$= (I/2)^2 \pi (3 - 16/\pi)^2 = (I/2)^2 \pi (1.37) \qquad (9)$$

The factor π comes in because the resistance of one side of the armature has been assumed to be equal to π.

If this machine were acting as a direct-current generator, delivering the current, I, the heating of each side of the armature would be proportional to $(I/2)^2 \pi$, and hence we see that the I^2R loss in the single-phase converter is 37 per cent. greater for the same output than the same machine as a direct-current generator. To give the same heating the output of the rotary must be decreased. The rating of a



FIGS. 14 AND 15.—RATIOS OF CURRENTS.

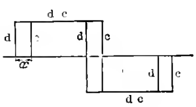


FIG. 16.—RECTANGULAR CURRENTS IN COILS D & C.

direct-current machine must be $1/\sqrt{1.37} = .85$ x rating as direct-current generator, for the same heating.

In the two-phase converter, Fig. 14, we must consider the current in three parts of the armature. These currents are as follows:

Current between B_2 and $a_1 = I/2\ (1 + \cos \Theta - \sin \Theta)$

Current between a_1 and $b_1 = I/2\ (1 - \cos \Theta - \sin \Theta)$

Current between b_1 and $B_1 = I/2\ (1 - \cos \Theta + \sin \Theta)$

To get the average heating we integrate between the limits of O and $\pi/2$, because from $\Theta = 0$ to $\Theta = \pi/2$ the armature current passes through all possible values. We get, then, by proceeding as before,

Average heating

$$= 2/\pi\ (I/2)^2 \int_0^{\pi/2} (2 \pi + 4 \Theta \cos \Theta - 2 \pi \cos \Theta - 4 \Theta \sin \Theta)\, d\Theta$$

$$= (I/2)^2 \pi\ (2 - 16/\pi^2) = (I/2)^2 \pi\ (.37) \qquad (10)$$

Here we see that the heating of a two-phase converter is only 37 per cent. of that of a direct-current generator for the same output. In order to get the same heating the output may be increased to $1/\sqrt{.37} = 1.64$ times output of direct-current machine. The capacity of the two-phase converters is $\frac{1.64}{.85} = 1.93$ times that of the single-phase.

While the above method gives us a good insight into the real reason for the decreased heating of polyphase converters it becomes laborious to work out each case separately. A general method due to Mr. Steinmetz will now be given. No clearer piece of mathematical reasoning has ever been given.

In a converter having n collector rings tapping the armature at n equal spaces around the commutator the voltage between adjacent collector rings will be:

$$E^1 = \frac{E \sin (\pi/n)}{\sqrt{2}} \qquad 3(b)$$

(In a single-phase converter $n = 2$, in a two-phase converter $n = 4$, etc.)

The current between two collector rings may be obtained by the equation (assuming no lag of alternating current):

$$n E' I' = E I \qquad (11)$$

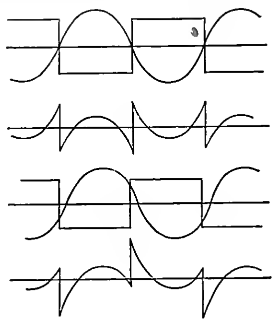
By substituting the value of E' we obtain

$$I' = \frac{I\sqrt{2}}{n \sin \pi/n} \qquad (12)$$

Now consider a coil, c, of the armature at an angular distance a from the position midway between two adjacent collector rings, as in Fig. 15. The alternating e.m.f., and therefore the current between a_1a_2 will reach a maximum value when the angle ϕ is 90°. Now it is evident that the direct current in every armature coil reverses when the coil passes under brush B_1 or B_2. The alternating current, however, in any armature coil between a_1 and a_2 is the same. If we plot the rectangular direct current in the coil, d, counting time when the coil passes from one side of the brush to the other we obtain the curve, d, shown in Fig. 16. In successive armature coils the rectangular currents are displaced in phase. That is, for example, the current in the coil c is as shown by the curve, c, in Fig. 16. The alternating current being the same throughout the section between a_1 and a_2 the direct and alternating currents are thrown more and more out of phase as we pass from d to a_1 or a_2, as shown in Figs. 17, 18, 19 and 20. At the alternating leads, a_1 and a_2, the alternating and direct currents are out of phase by the angle π/n.

FIGS. 17, 18, 19 AND 20.

The direct current, then, in the coil, c, is $I/2$ for half a period; that is, from the time the coil passes from B_2 to B_1. The current in coil d is $\sqrt{2}I' \sin \phi$, I' being taken from equation (12). The alter-



FIGS. 17, 18, 19 AND 20.—PHASE RELATIONS.

nating current in coil c is $\sqrt{2}\ I' \sin (\phi - a)$. By substituting the value of I' from equation (12) we obtain

$$\text{Alternating current} = \frac{2I \sin (\phi - a)}{n \sin \pi/n} \qquad (13)$$

The actual current in the armature coil, c, is the difference between the alternating and direct current, and is therefore equal to

$$i_0 = \frac{2I \sin (\phi - a) - I/2}{n \sin \pi/n}$$

$$= I/2 \left[\frac{4 \sin (\phi - a)}{n \sin \pi/n.} - 1 \right]$$

The effective value of this current is

$$I_0 = \sqrt{1/\pi \int_0^\pi i_0^2 d\phi} = I/2 \sqrt{1/\pi \int_0^\pi \frac{(4 \sin (\phi - a) - 1)\, d\phi}{n \sin \pi/n}}$$

$$= I/2 \sqrt{\frac{8}{n^2 \sin^2 \pi/n} + 1 - \frac{16 \cos a}{n \pi \sin \pi/n}} \qquad (14)$$

$I/2$ is the armature current of a direct-current generator, and hence for the same output the ratio of the heating of the coil, *c*, of the converter to the heating when used as a direct-current generator is

$$Y\,a = \left(\frac{I_0}{I/2}\right)^2 = \frac{8}{n^2 \sin^2 \pi/n} + 1 - \frac{16 \cos a}{n \pi \sin \pi/n} \qquad (15)$$

This ratio is a maximum at the alternating leads a_1 and a_2, where $a = \pi/n$, and is a minimum for the coil, *d*, midway between a_1 and a_2. The value of Ym and Yo, the maximum and minimum values of $Y\,a$ may be obtained from equation (15) by substituting $a = O$ and $a = \pi/n$.

The average heating of the armature is obtained by integrating $Y\,a$ over the width of the coil between a_1 and a_2. Doing this we obtain

$$\text{Average heating} = Y\,a = n/\pi \int_0^{\pi/n} Y\,a\, d\,a$$

$$= \frac{8}{n^2 \sin^2 \pi/n} + 1 - 16/\pi^2 \qquad (16)$$

By substituting $n = 2$ and $n = 4$ we verify equations (9) and (10). The rating of the converter will be

$$\text{Rating} = 1/\sqrt{Y a} \qquad (17)$$

The following table, given by Steinmetz, may be worked out by substituting different values of n:

Type.	Dir.-Cur. Gen.	Single Phase.	3 Phase.	4 Phase.	6 Phase.	12 Phase.	∞ Phase.
n		2	3	4	6	12	
Yo	1.00	.45	.225	.20	.19	.187	.187
Ym	1.00	3.00	1.20	.73	.42	.24	
Ya	1.00	1.37	.555	.37	.26	.20	
Rating (by mean arm. heating)	1.00	.85	1.34	1.64	1.96	2.24	2.31

For tables of capacities taking into account mechanical losses or wattless currents the reader is referred to Steinmetz's "Elements of Electrical Engineering."

ARMATURE REACTION.

Consider the single-phase converter. The direct current may be considered as flowing down each side of the armature from brush to brush as though the alternating current were not present. With the brushes in the neutral position this would give us a magnetomotive force which may be represented by the line *s o*, Fig. 21, the point *o* being the centre of the larger circle. When a_1 and a_2 are directly under the brushes; the alternating current is double the direct current, but opposite in direction. The M.M.F. of the

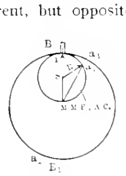


FIG. 21.—ARMATURE REACTION OF SINGLE-PHASE CONVERTER.

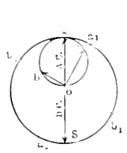

FIG. 22.—ARMATURE REACTION OF TWO-PHASE CONVERTER.

alternating current when a_1 and a_2 are under the brushes will then be represented in magnitude and direction by *O T*, the diameter of the small circle in Fig. 21. This gives the resultant M.M.F. of *s T*.

When a_1a_2 have moved to the position shown in Fig. 21, the M.M.F. of the alternating current will be represented by the line *o a'*. The locus of the alternating M.M.F. may be easily seen to be the circle *o T a'*. In whatever position the alternating leads are, the resultant M.M.F. of direct and alternating current gives a vector of constant magnitude and the direction is the line giving the two alternating-current taps (this in a two-pole machine) *s T*. *s T* is a vector rotating with twice the frequency of the alternating current. The armature reaction of a single-phase converter, therefore, passes from a generator reaction to a motor reaction twice the revolution. On account of this the commutation of the direct-current converter is not as good as that of the polyphase converter.

In the polyphase converter the armature reaction is practically absent, as may be easily shown. The demonstration will be given for a two-phase converter.

In Fig. 22 the line *o s* represents the direct-current M.M.F. (for the same current intake *o s*, Fig. 22, and *s o*, Fig 21, will be the same

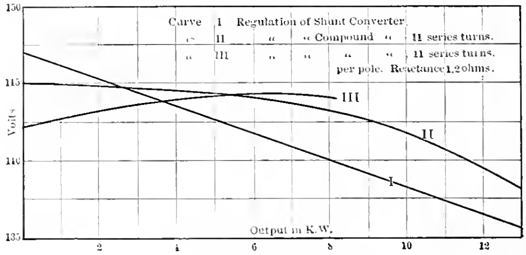

FIG. 23.—REGULATION OF CONVERTER.

magnitude, but to give a simple result in each case a different scale is taken). The M.M.F. of phase a_1a_2 will be again *o a'*, and the M.M.F. of phase b_1b_2 will be *ob'*. The resultant of *oa'* and *ob'* gives the length *o T*, which is equal and opposite to the M.M.F. of the direct current: Hence the alternating and direct current M.M.F. are balanced, giving little reaction for a balanced polyphase converter.

COMPOUNDING OF CONVERTER.

At constant impressed alternating potential the direct current voltage will be practically constant also. Varying the field excitation of the converter will not materially affect the ratio of conversion. The regulation of a converter is better than that of a direct-current, shunt-wound generator on account of the absence of armature reaction. In Fig. 23, curve I shows the regulation of a shunt-wound converter, and curve, II, the regulation when the converter was compounded with 11 turns per pole. The only way to compound the rotary is to automatically vary the pressure at the alternating-terminals. This can be done by introducing reactances into the line and then compound-winding the rotary, so that as the load comes on the rotary the leading alternating current drawn by the machine will cause a rise in pressure through the reactance. This problem then is the same as that of compounding a synchronous motor[1] so the changes of load will affect the pressure at the machine terminals in a desired way. Curve III, Fig. 23, gives the regulation of a converter with external reactances.

Trolley to Haul Logs.

It is stated from Bangor, Maine, that a trolley system is in successful operation in the Maine woods, hauling heavy loads of logs. It is the invention of A. O. Lombard, of Waterville, and is somewhat like the flat construction cars used on street railways. It is twenty feet long and six feet wide, and its wheels, like those of the steam hauler, run on an endless lag bed, supported on roller bearings, while the framework of the bed is so constructed that the machine accommodates itself to all knolls and other irregularities in the road. The cog gears which do the driving are so constructed that no matter what the position of the machine they always turn within each other. The machine is fitted with two twenty-five horse-power motors and a Westinghouse controller, and is geared to run about four miles an hour. Over the axle of the machine a rocker is pivoted, and on this is rested one end of the load of logs to be hauled, the rear end of the load being supported by a common logging sled. Other sled loads of logs may be attached in tow. The hauling capacity of the machine has been tested as high as 58,280 ft. at a trip.

The electric machine runs over a road seven miles long, the usual trolley system being used, current being generated at a water power plant with steam reserve. Illuminating current is also supplied by the plant, and the logging roads and landings are brilliantly lighted with electricity.

[1] Synchronous Motor Calculations, by F. G. Baum, ELECTRICAL WORLD AND ENGINEER, May 17, 1902.

The Telephone Substation.—III.

By ARTHUR V. ABBOTT, C.E.

The mounting of an induction coil usually depends on the place where it is to be used. Coils which accompany a wall or cabinet set are merely wound on a spool and placed in a chamber made by expanding the base of the transmitter arm, as illustrated in Fig. 14. For switchboards and desk sets when the coil is to be attached to neighboring woodwork it is usually mounted on a wooden base, *a*, as in Figs. 10, 12 and 13. Fig. 15 is from a photograph of the group of coil dissected to form Table 5.

As an aid in designing the winding of induction and other coils Table 6 is appended, collected from experimental data gained in the winding of many coils with various kinds of insulation.

Owing to the scarcity of data upon induction coil construction, the design of a new coil is more or less a matter of experiment, and for this purpose it is well after roughly designing the windings to construct experimental coils which shall enable the design to be tested.

For this purpose it is advantageous to arrange the primary and secondary to be separable so that the combination of various primaries with other secondaries may be tested. For example: Assume that a coil having 300 turns in the primary and 2,500 turns in the secondary be considered desirable. Assume the core to be from ½ in. in diameter and provide a winding space of 5 ins., construct five such cores; wind one with two layers of No. 24 wire. This will give approximately 300 turns. Wind one other core with No. 13 wire, obtaining 100 turns and one with No. 19 wire, giving 200 turns; also one with No. 27 wire, obtaining 400 turns and one with No. 32 wire, giving 500 turns. Construct in a similar manner five secondaries, each wound upon a paper tube so that they may be slipped over any one of the primaries. One secondary should be wound of No. 33 wire, giving 2,500 turns in five layers; one with No. 24, giving 1,000 turns; one with No. 28, giving 1,500; one with No. 36, giving 3,000, and one with No. 35, giving 4,000 turns. As each secondary may be tested with

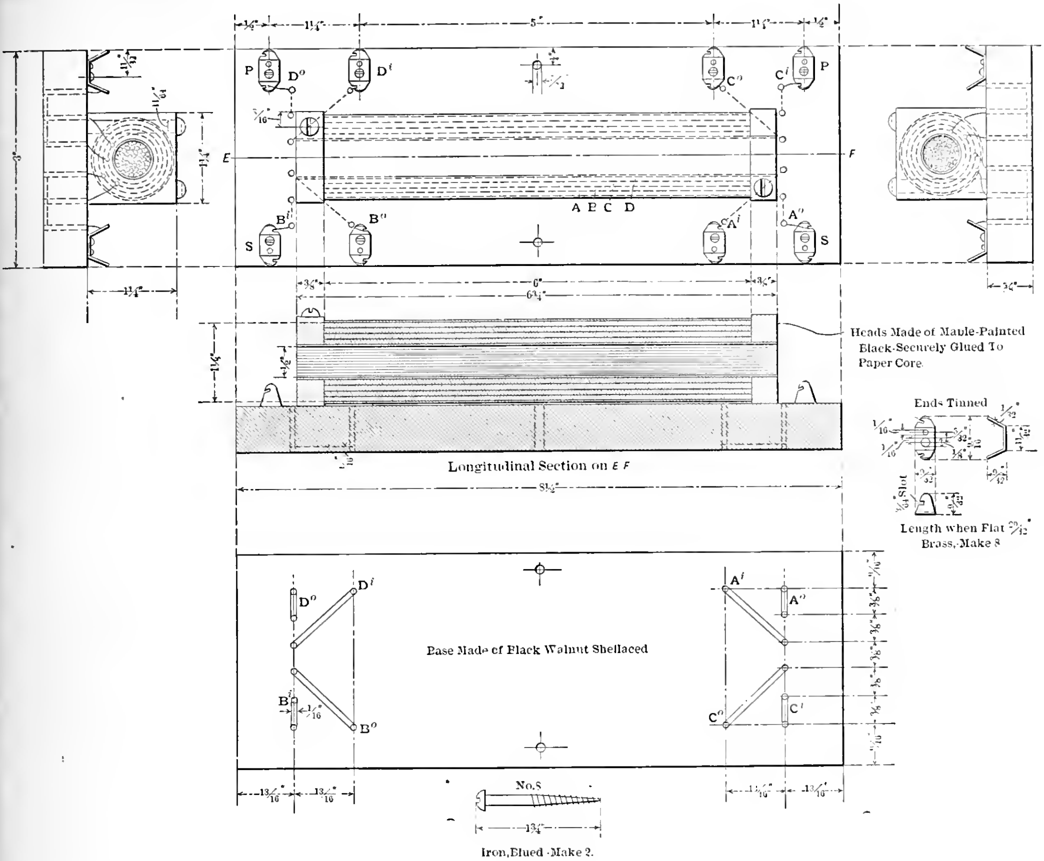

FIG. 12.—DOUBLE-WOUND COIL.

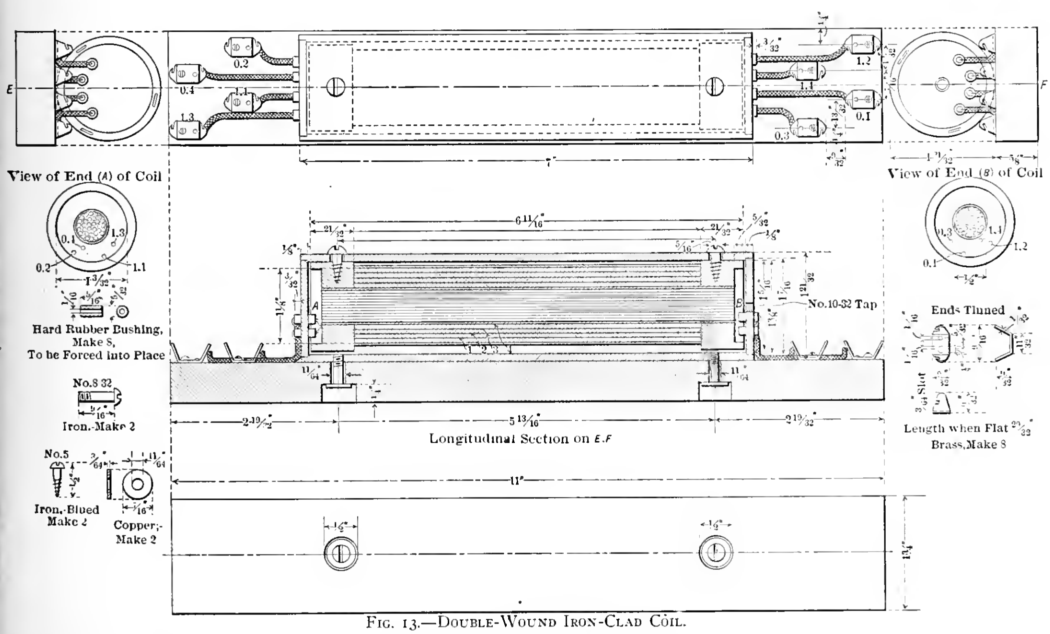

FIG. 13.—DOUBLE-WOUND IRON-CLAD COIL.

any one of the previous primaries, the construction of five coils will give twenty-five combinations. A trial with each of these will show which combination gives, on the whole, the best results under the particular circumstances the coil is to be used, and from a prelimi-

SPECIFICATIONS FOR FIG. 10.

Core: Bundle of No. 24 soft iron wire.
- Diameter of core, ½ in.
- Length of core, 6¾ in.
- Winding space, 6 in.
- Paper insulation around core 1/32 in. thick.

Winding: Inside winding.
- Resistance, .5 ohms.
- 380 turns No. 18 single covered wire wound from end to end of core in three layers. Cotton covered.
- Two layers of common paper insulation around it.

Outside winding:
- Resistance, 84 ohms on each side = 168 ohms total.
- 2500 turns on each side = 5000 turns total.
- Wound from end to center and from center to end of core.
- Secondary. Two coils separated by hard rubber ring 1/16 in. thick.

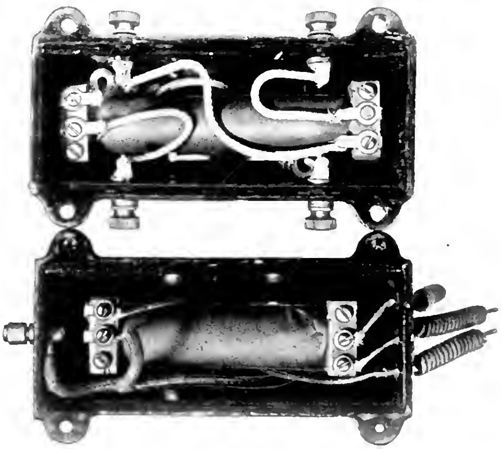

FIG. 14.—INDUCTION COIL IN BASE OF TRANSMITTER.

Terminals: Primaries to operator's telephone.
- L. L. to keyboard.
- T. T. to telephone.
- G. to center of telephone or ground.

German silver winding wound differentially, insulated by a covering of heavy wrapping paper to prevent contact with the iron casing of the coil.

Terminals: The winding which includes the 50 ohms of copper and the 100 ohms of German silver is the primary and will be stamped 150 ohms at the terminals.
- The 50-ohm winding is the secondary and will be stamped 50 ohms at the terminals.

SPECIFICATIONS FOR FIG. 12.

Frame: Two heads, maple painted black ⅜ in. thick 1¼ in. by 1¼ in. Core tube, paper made of a sheet 6¾ in. wide, 9 in. long, .004 in. thick rolled around a mandrel ½ in. diameter and glued.
- Tube glued into heads.

Base: Black walnut, varnished, 11 in. long, 1¾ in. wide, ⅝ in. thick.

Core: Best annealed iron wire, varnished, cut 6¾ in. long.
- Diameter of wire, .016 in.

Primary: Single white silk covered copper wire.
- Diameter, 0.16 in., No. 28 B. & S.; to be wound in two parts, each having 1550 turns.
- Resistance, 16 ohms.
- Terminals to be reinforced with stranded wire throughout and soldered to clips as in drawings.
- Winding to be in two layers.

Secondary: Single white silk-covered copper wire diameter, .013, No. 28 B. & S.; to be wound in two parts, each having 1550 turns.
- Resistance, 23 ohms.
- Terminals to be reinforced with stranded wire and brought out and soldered to clips as in drawing.
- Winding to be in two layers.
- Coil to be wrapped with black "seal cloth."

SPECIFICATIONS FOR FIG. 13.

Frame: Two heads to be made of maple, varnished, shaped as at *A A B*, Fig 13. Heads to be 11/16 in. thick, 1 5/16 in. in diameter.

Core Turn: To be made of a sheet of paper 6⅜ in. wide, 9 in. long, .004 in. thick, rolled on a mandrel ½ in. in diameter and glued.
- Tube to be glued into heads.

Base: Black walnut, varnished, 11 in. long, 1¾ in. wide, ⅝ in. thick.

Iron Shield: Annealed wrought iron pipe, 6⅞ in. long, 1¼ in. diameter inside, recessed as shown. Two caps ⅛ in. thick cut to fit pipe.
- Heads to be secured by upsetting pipe after coil is in place. All to have two coats of black paint.

Core: Best annealed wrought iron wire, cut 6¾ in. long, varnished.
- Diameter of wire, .016 in.

Primary: To be of best white single silk covered copper wire.
- Diameter, .0142 m., No. 27 B. & S.; to be wound in two parts, each having 1565 turns and a resistance, 14 ohms. Each part to have two layers.

Secondary: To be of best white single silk covered copper wire.
- Diameter, .0142 m., No. 27 B. & S.; to be wound in two parts, each having 1565 turns; resistance to be 21 ohms. Each part to have two layers.
- Coil to be wrapped with black "seal cloth."

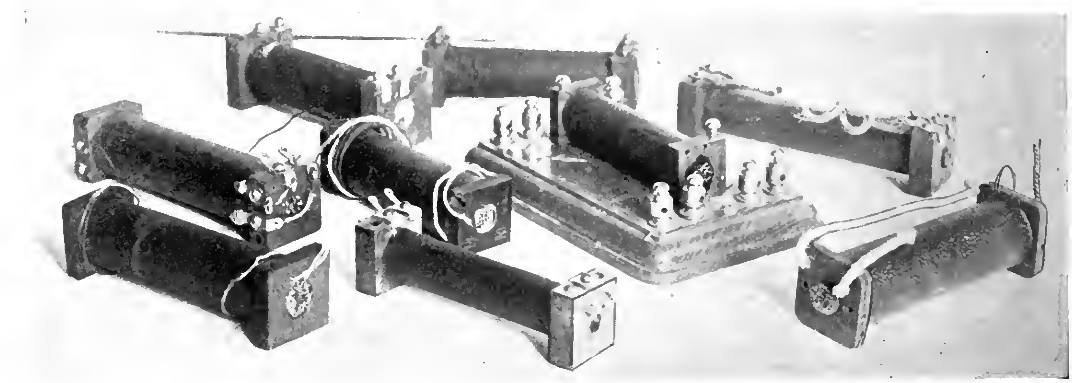

FIG. 15.—A GROUP OF INDUCTION COILS.

SPECIFICATIONS FOR FIG. 11.

Core: 200 soft iron punchings 0.12 in. thick.
- Diameter 2¼x½ in.
- Winding space, 1 1/16 in.
- Heavy parafined paper insulation.

Winding: Inside wiring.
- Resistance, 50 ohms each.
- 2 No. 30 single cotton covered copper wires wound parallel.

Outside winding:
- Resistance, 100 ohms.
- German silver wire put on and connected in series with one of the 50-ohm coils.

Terminals: The terminals shall consist of two (2) strands of wire of the same description as that herein specified for the winding of the coil. That part of the terminal which extends beyond the iron sheath shall be covered with a braided cotton covering. The terminals shall be securely soldered to their respective terminal clips without the use of acid.

Finish: The coil and its accessories shall be assembled and finished in a workmanlike manner.

Test: The fulfillment of the electrical requirements herein called for shall be determined by a comparative test for efficiency against a standard coil.

nary test of this kind the probable final proportions of the most desirable coil can be readily determined.

CURRENT NEWS AND NOTES.

NIGHT ELECTRICAL SCHOOL IN SCHENECTADY.—Several progressive employees of the General Electric Company at Schenectady, N. Y., have initiated a project having for its purpose the founding of a night electrical school.

WASHINGTON UNDERGROUND WIRES.—A bill introduced by Senator Gallinger and reported to the Senate with the recommendation for favorable action by Senator Foraker from the Senate Committee on the District of Columbia, requires all telegraph wires in the District to be put under ground under penalty of a fine of $25 per day.

GAMBLING BY TELEPHONE.—Mayor Harrison has appealed to the Chicago Telephone Company for its co-operation in suppressing pool rooms and "hand books". Warfare on tickers has resulted in substituting telephones and the company finds itself in the peculiar position of a common carrier obliged to accept and maintain the secrecy of all business offered to it in ignorance of its purport, and the operators are forbidden by the rules to listen in to determine whether gambling is being conducted. Listening or "tapping off" the line is in direct violation of the law.

DERI DIRECT-CURRENT ELECTRIC RAILWAY SYSTEM.—A patent granted March 29 to Max Deri, of Vienna, Austria, and assigned to the Stanley Electric Manufacturing Company relates to an direct-current power transmission system stated to be particularly adaptable to traction use. A railway system is divided into such a number of sections that not more than one car shall be on a given section at any time. Each section is fed by an independent generator with two windings in opposition, one being separately excited, and the other in series with the armature. With this arrangement the line voltage varies inversely with the current, and a motor can, therefore, be connected directly with the line from a state of rest or non-excited condition without the intervention of resistance.

STORAGE BATTERY PATENTS.—The only three electrochemical patents granted on March 29 refer to storage battery inventions. Two patents, granted to Mr. C. P. Elieson, of Paris, relate to details of mechanical construction of the grid, and a patent of Mr. A. Meygret, of Paris, refers to a protective envelope for the plates for the purpose of preventing the active material dropping off the plates. This envelope is produced by dipping the plate or grid, after the active material has been applied to it, in a bath consisting of castor oil, essence of turpentine, octonitric cellulose, and ordinary nitrate of cellulose. This method is stated to give an elastic coating which presses the active material against the supporting grid. In order to render it porous, it is afterwards mechanically perforated or provided with a series of fine gashes.

BRITISH STREET RAILWAYS.—The latest Board of Trade returns show that there are 296 tramway undertakings in the United Kingdom, which have cost $200,000,000. These have nearly all been created in the past twenty-five years. Of the total number 142 are owned by municipalities and 154 by private companies. The municipal undertakings, though less in number, have more mileage and cost about $120,000,000; the private, over $80,000,000. The total length of both is over 1,700 miles. Some of the municipal tramways are alleged to make handsome profits, which materially reduce local taxes. During the current year, it is estimated, Nottingham will clear $90,000 from this source, Liverpool $123,000, Leeds $300,000 and Manchester $250,000. In none of these cities do the facilities begin to compare with those afforded in like American cities under private ownership.

ELECTRICAL POLE LINES.—Mr. H. Von Schrenk, chief of the Forest Products Division of the Government Bureau of Forestry in the United States Department of Agriculture, has recently issued a letter and a circular asking for information with regard to poles, pins and cross arms used in the telephone and telegraph industry. He states that the Bureau is to issue a bulletin on the subject of such lumber. A number of questions are asked bearing upon this subject, as to standard specifications, sources of supply, seasoning, average length of life, wire capacity, etc. These questions appear to be somewhat in line with those included in the telegraph and telephone schedules issued by the United States Census Office, with regard to poles, etc., used for those branches of electrical work. The inquiry appears to be based upon the increasing difficulty of obtaining suitable timber for these purposes.

NEW USE FOR THE SEARCHLIGHT.—Prof. C. L. Cory, of the University of California, who is at the head of the electrical engineering department, recently caused a sensation at Berkeley, Cal., by adopting modern military methods to prevent a prohibited college "rush." One of the classes had planned to storm a high hill near the University and paint their class number in white on the hillside where it could be seen for miles around. Prof. Cory had an electric searchlight trained on the hill from the top of the mining building. A force of armed policemen lay in ambush until 1 A.M. when one of them gave the signal, which resulted in the capture of the luckless students, revealed by the powerful rays turned on them as they scaled the heights. About a dozen of the more determined ones were handcuffed until their names and addresses could be ascertained.

A NEW COHERER.—Prof. J. Chunder Bose, the distinguished Hindoo physicist, is represented in the patent budget of March 29 by a patent on a new form of coherer. According to the theory of Prof. Bose, the changes produced on or in the sensitive substances of the coherer are due to molecular distortion, and in order to obtain the best results with the coherer it is necessary that this distortion shall be removed before fresh radiations are received. This is usually done by resort to tapping contrivances, but Prof. Bose offers a method whereby the necessary effect is produced by subjecting the sensitive substances to torsional distortion, imparting to the tube carrying the sensitive substance either a one direction or an oscillatory or vibrational twist. He has, moreover, discovered that certain substances such as galena, tellurium, lead, tin, allotropic silver and a number of others, possess the property of rapid self-recovery from the effects of Hertzian waves. As illustrated, at the end of two pivoted arms are two contact pieces of such material, one being in the form of a plain cylinder, and the other pointed and bearing on the first mentioned. The contacts are normally held together by a spring, the pressure of which can be regulated with great delicacy by means of a micrometer screw. It is stated that this apparatus is self-recovering when the sensitive substance is of the kind enumerated, the distortion produced in the contacts by a wave radiation thereon being automatically removed upon the cessation of the wave.

CONTROLLING INDUCTION MOTORS.—A patent issued several years ago to Analto P. Zani, of Milan, Italy, described an arrangement for starting induction motors, whereby the usual large starting current could be cut down. In this arrangement the rotor had two paths for the induced current, one having a high ohmic resistance and little, if any, self-induction, and the other having an almost negligible resistance, but a comparatively high self-induction. In starting a motor with such an arrangement, a large proportion of the current generated in the rotor will at first flow through the high-resistance path, due to the high frequency of the induced current at low speed. As the speed of the motor rises the frequency of the current decreases, thus correspondingly reducing the reactance in the low-resistance path, until finally when the speed of the motor approaches normal, the impedance of this path becomes so small that nearly all the current generated will flow through it. In a patent issued March 29 it is stated that substantially the same results may be produced with but a single path in the rotor or induced circuit, consisting in effect of the primary of a transformer having a low-resistance path. As illustrated, mounted on the shaft of the rotor are three coils surrounding the same number of cores, the ends of the windings being connected with the ends of the rotor circuit. It has been found that if the members constituting the core magnetic circuit are massive in construction and unlaminated, distinct secondary windings are not required, the magnetic material offering low-resistance inductive paths for eddy currents set up, these eddy currents constituting the secondary current of the transformer. An arrangement is provided whereby when the motor arrives at normal speed the transformer magnetic circuit is opened by means of centrifugal force.

LETTERS TO THE EDITORS.

Steam Turbine Economy.

To the Editors of Electrical World and Engineer:

SIRS:—In your issue of March 5 Mr. Cyrus Robinson, referring to the results of tests of a 1,250-kw steam turbine, published in your issue of February 20, made some criticisms, to which I would ask your kind permission to reply. I quote from Mr. Robinson's letter the following paragraph:

"We have been informed so many times by the manufacturers of turbines of the necessity of high—in fact almost theoretical—vacuum, that it is somewhat of a question if the high economies claimed are not more than offset by the means adopted to obtain them; viz.: the use of large air and circulating pumps, and superheaters, etc."

It is a surprise to me to learn that any manufacturers of turbines have stated that the turbine requires a high vacuum, and I am sure that it would be interesting to your readers to learn from Mr. Robinson what manufacturers of turbines have made such a statement, and where.

It is a fact, as everyone knows who is acquainted with the theory of the steam turbine, that, as the vacuum increases, each successive increment of vacuum is of greater value in the steam turbine than in the reciprocating engine. It follows, therefore, that it is somewhat more to the advantage of the owner of the steam plant to produce a high vacuum for the turbine than for the reciprocating engine, as he gets a greater return for his outlay in the condensing plant. The desirability—not the necessity—of a high vacuum in the steam turbine, as well as in the reciprocating engine, should not be allowed such a prominent place in one's mind as to overshadow the fact that the steam turbine is highly economical with a much lower vacuum than was obtained in the tests above referred to.

In this connection it should be remembered that not only with turbines, but with reciprocating engines, steam users are appreciating more and more every day the desirability of a high vacuum as conducive to station economy. There is to be found in the market to-day condensing apparatus far superior to any which could be obtained a few years ago, and at prices but little higher than those of the less efficient apparatus which was formerly to be had. With such apparatus, at a less operating expense than with poorer apparatus, such vacua as in the tests above cited are easily obtained, either for use with the reciprocating engine or the turbine.

Incidentally I would say that some, if not all, makes of steam turbines are now so constructed that it is absolutely impossible for any air to get into the exhaust steam, except such as may have come with the steam from the boilers, whereas in the reciprocating engine more or less air enters at the low-pressure piston rod and valve stem stuffing boxes; the amount of air so admitted increasing as the packing wears. With the steam turbine, therefore, for a given amount of exhaust steam, a high vacuum is more easily obtained than with the reciprocating engine. This being the case, why should not the steam turbine fairly derive an advantage from the high vacuum which it incidentally assists to create?

Mr. Robinson says that it is unfortunate that I did not give the consumption of the auxiliaries, particularly the air and circulating pumps and superheaters. No observations of these items were made during the tests referred to, principally for the reason that these auxiliaries in our testing plant are not installed as they should be in a power station with due regard to economy, but rather with regard to the necessary flexibility of a plant which is used for testing machines of various capacities temporarily located in various parts of the testing shop. I have quite recently, however, had an opportunity to get indicator cards from the steam cylinder of the same air pump during the test of a turbine which is an exact duplicate of the one previously tested. With the turbine developing 2,120 brake hp, or considerably above rated load, with the barometer at 29.18, and carrying a vacuum of 27.89 in. by mercury column, equivalent to 28.71 in. referred to a 30-in. barometer, the indicated power of the air pump engine was 14.4, or less than seven-tenths of one per cent. of the power developed by the turbine.

A good proportion of this power would be required to maintain only such a vacuum as is found in the older and inferior forms of condensing apparatus. But, for the sake of argument, let us assume that the whole of this power was expended in increasing the vacuum from 27 to 28 in., and let us suppose that the air pump engine consumes as much as 25 pounds of steam per indicated hp-hour. This would call for an expenditure of 260 pounds of steam per hour. Now, referring to the results of turbine tests in your issue of February 20, it will be seen that, when using saturated steam, an increase from 27-in. to 28-in. vacuum decreased the steam consumption of the turbine by 0.68 pound per kw-hour. At the rated load of 1,250 kw, therefore, the steam consumption of the turbine was bettered to the extent of 850 pounds per hour by the increase in vacuum.

We therefore have a balance in favor of the better vacuum equivalent to 850-360-490 pounds of steam per hour, which is a little over 2 per cent. of the total steam consumption of the turbine. Even this 2 per cent. would be worth saving, but as a matter of fact the saving is much greater, because the power required to increase the vacuum can be nowhere near as great as that above assumed. Moreover, in this testing plant the condensing apparatus works under great disadvantage, for the reason that it is connected up to an extensive exhaust pipe system having an abnormal number of turns, offsets, etc., in order to lead to the various testing stands, and the exhaust piping is handicapped by a large number of blank flanges and other temporary joints, thus making it more difficult to maintain a vacuum than in a regular power plant.

As to the power required for working the circulating pump, any data which might be derived from the testing plant would be misleading, as the exigencies incident to a combination of testing and manufacturing operations require a plant quite different from what would be used in a regular power station. In a properly designed power station, moreover, the power required to work the circulating pump of a modern condensing apparatus is extremely small, as the pump requires to do nothing but overcome the friction of the pipes and condenser tubes, etc. With everything properly designed and installed, the entire power required to work not only the air pump, but the circulating pump could be charged to the increase of vacuum from 27 in. to 28 in. and still leave a paying margin of profit, no matter whether the condensing apparatus is used in connection with a steam turbine or with a reciprocating engine.

As to superheat, the gain to be derived from this, in a properly-designed plant, either in a steam turbine or in a reciprocating engine, is too well known to require any defense. In the above referred-to turbine tests, however, the economic results were stated both with and without superheat, and the reader is, therefore, enabled to make the necessary comparisons.

I would quote further from Mr. Robinson's criticism as follows:

"Articles of this kind are apt to be misleading, and as an illustration the operation of a compound reciprocating engine by means of the air pump may be cited, where no steam is actually consumed by the engine itself, the work being done entirely by the 'vacuum,' i. e., atmospheric pressure."

This might be said of any test of any kind of apparatus. In this case, however, as will be seen by referring to the article in your issue of February 20, we took the precaution to have all of the results of the turbine test verified and certified to by a disinterested engineer, whose reputation is above criticism, namely, Mr. Julian Kennedy, the well-known consulting engineer.

PITTSBURG, PA. A. M. MATTICE.

British Technical Education.

To the Editors of Electrical World and Engineer:

SIRS:—I beg you to allow me as an unprejudiced American educated in England, to enter a voice of protest against your editorial on English technical education, in the issue of March 26. I must first point out that your comparison of time spent in the colleges is not quite fair. Nearly all of the men at my college, the Central Technical College, of London, had spent from one to four years at either one of the universities of Oxford or Cambridge or the scientific school of Dulwich College, or at the Finsbury Technical College or some equivalent institution. It will not do to say that the time devoted to technical education in England is short, because the average time spent at the Finsbury College is, say, two years. It is necessary to follow the student to the higher college before one can accurately judge what he is doing. The matriculation examination of the Central covers the subjects treated in the Freshman year of the American college, so that a student practically enters at once into the equivalent of the American sophomore year. That is why the course at the Central Technical college extends over only three years, instead of four, as in America. An experience of four years in London technical institutions and four years acquaintance with American college graduates, leads me to the conclusion that the American college, in attempting to be very practical, neglects the fundamental knowledge that is so important to the engineer. The English professors, unlike their American brethren, do not attempt to grind out experienced engineers by the wholesale. Care is taken to give the men a good grounding in fundamentals, something that American technical graduates are usually sadly lacking in. I shall never forget my first experience with a Massachusetts Institute of Technology man. He was fresh from college, but seemed to know a great deal about practical details of machine design, wiring, railway work and so forth. We were discussing a recent paper on transformers, published by the Institute, when he asked, "Why does the reading of an ammeter in a transformer circuit include the wattless current? I cannot see how a wattless current can operate an ammeter." Probably he was not a representative M. I. T. man—I hope not—but the mere fact that a man could spend four years at college and get a degree, and then ask such an idiotic question illustrates that the college faculty considers a practical knowledge of transformers more important than a knowledge of the fundamental principles governing these apparatus. I don't think college the correct place to learn engineering practice—that can only be learned by hard work in the shops and drafting room.

Another reason why there are so many students in England who do not take the full three years' course is that men who cannot follow the work are dropped. They are either requested to leave or expelled, for the diplomas and certificates are not awarded to all as they apparently are in many of our American colleges.

Let us not rejoice too noisily over our institutions until we have learned all we can from our friends across the ocean.

NEW YORK CITY. WM. A. DEL MAR.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

DYNAMOS, MOTORS AND TRANSFORMERS.

Voltage Variation of a Direct-Current Dynamo and a Direct-Current Voltage Transformer.—ALIAMET.—An illustrated description of a direct machine of Lanhoffer. The voltage which can be obtained at the terminals of a direct-current dynamo cannot be varied within wide limits, since an upper limit is set by the saturation of the magnetic circuit while the lower limit is determined by the conditions of good commutation. If the ratio of the highest and lowest voltage under which a dynamo can be operated successfully is called the coefficient of variation of the tension, this coefficient is generally below 1.5. The machine of Lanhoffer enables one to increase it over 5. It consists, as shown in Fig. 1, of two machines with inde-

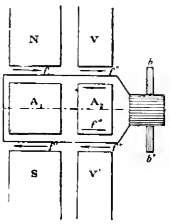

FIG. 1.—VOLTAGE VARIATION.

pendent stationary field systems while the two armature cores are mounted on the same axle. The armature winding passes over both cores. The excitation of the field $N S$ is kept constant while the exciting current of the field $V V'$ can be varied and reversed. For this reason a rheostat with a reversing switch is provided in the exciting circuit of $V V'$. The field $N S$ may be excited either by a separate source of current or a method of self-excitation may be used; in the latter case the exciting current for $N S$ is furnished from a special winding which is wound only around the core A_1 and not around A_2. If the e.m.f's induced in the common armature circuit by the field $V V'$ are of the same sign as the e.m.f's induced by the field $N S$, the machine $V A_2 V'$ acts as a booster; if the e.m.f's are of the opposite sign, this machine acts as a negative booster. The same arrangement may be used as a direct-current voltage transformer with a ratio of transformation being variable within rather wide limits. In this case, of course, a second commutator must be provided which is supplied from the external circuit at constant voltage. This commutator is connected to the armature winding of core A_1 alone. The transformed current is taken up from the brushes $b b'$. The author gives some theoretical notes on the operation of this machine with special reference to armature reaction and to commutation.—*La Revue Elec.*, February 1.

Speed and Type of Electric Motors.—An account of the discussion which followed the paper of Hobart on the comparative advantages of direct-current motors and induction motors for various speeds. This paper was abstracted in the Digest last week. Thompson said that the contrast between the designs of a number of machines of the same rated output emphasizes several very important features of design. In comparing machines of one kind with those of another, it is useful to go back to first principles and to apply a formula which is applicable to all cases. He has found the following formula very convenient for comparing all kinds of motors and generators, whether direct-current, single-phase or three-phase alternating current. It states that the output of the machine in kilovolt-amperes divided by the speed in revolutions per minute equals the magnetic flux multiplied by a coefficient which varies with the type of machine (being 1 for continuous-current machines and theoretically 1.11 for alternating-current machines), multiplied by the diameter of armature, multiplied by the amperes per inch of armature, multiplied by the number of poles, the whole divided by 1.9×10^{12}. He shows that the eleven machines analyzed by Hobart show some very curious and interesting variations. Drysdale said that Hobart's result concerning cost might well be expressed by saying that the cost is about 25 cents per square centimeter of core area for the large machines discussed by him. Drysdale has found himself that small machines from 2 to 10 hp give a surprisingly uniform value of about 60 cents per square centimeter of core area, and he thinks that this is rather a valuable basis of comparison, since, when taken into consideration with the Steinmetz coefficient, it affords a considerable help in design. Meyer expressed the opinion that all the facts brought forward by Hobart are of a theoretical nature, and discussed several details.—Lond. *Elec.*, March 18.

Operation of Alternators in Parallel.—BOHLE.—A continuation of his illustrated paper. He shows that the mass of a fly-wheel should be directly proportional to the coefficient of fluctuation of energy and the work done by the engine, and inversely proportional to the coefficient of speed variation and the square of the speed. Multi-crank engines should be given a smaller coefficient of speed variation than single-cylinder sets. There is absolutely no reason why alternators driven by single-crank prime-movers should not give first-class results when running in parallel. Where trouble occurs it is almost always due to resonance. Trouble occurring with single-crank sets and being due to resonance is made worse by interference of oscillations and can be avoided by decreasing the fly-wheel mass if the coefficient of speed variation is as low as 1/200. The fly-wheel mass will still be large enough to count for any irregular changes. The coefficient of speed regulation should, however, never be larger than 1/100. In multi-crank sets, working under similar conditions, the coefficient of speed variation should not be less than 1/150, so that, whenever there is nearly resonance, the fly-wheel mass should be increased. 1/300 should, however, be the limit in the other direction, otherwise the machines become too expensive.—Lond. *Elec.*, March 18.

REFERENCES.

Compensated Series Motor.—OSNOS.—A long theoretical article in which the author develops the diagrams for the compensated series motor and draws from them some general conclusions. While the voltage at the terminals remains constant, the voltage at the stator increases with increasing speed, but the voltage at the rotor (between the brushes connected in series with the stator) always decreases. The stray fields have an effect equivalent to an increase of the primary stator field and a decrease of the primary rotor field or like an increase of the air-gap which always results in a greater phase difference, other things being equal. Concerning the arrangement of the slots he finds that the best arrangement is the uniformly distributed one with a coil breadth equal to the pole pitch.—*Elek. Zeit.*, March 17.

Single-Phase Commutator Motors.—Sumec.—The first part of a mathematical article in which the author intends to give a simple review of the properties of single-phase commutator motors. His method is to first give for each electric circuit of the system under consideration an equation of the e.m.f's and then to represent all these equations by means of vector diagrams. He intends to combine in this way the accuracy of mathematical methods with the clearness of the graphical methods.—*Zeit. f. Elek.* (Vienna), March 20.

Sparking of Dynamo.—Mailloux.—An article with reference to a former article of Browne, in which troubles were recorded that had been experienced with a dynamo sparking on account of a weakened magnetic field in an electrolytic refinery in which a number of tanks had been disconnected. He discusses briefly the possibility of sparkless commutation with full-load current at low e.m.f's and also discusses the prevention of the reversal of the magnetic field due to the counter e.m.f. of the electrolytic vats under certain conditions of switching.—*Electrochem. Ind.*, April.

Power.

High-Tension, Direct-Current Power Transmission.—A note on experiments made on the St. Maurice-Lausanne transmission line on which the Thury system is used. The earth was first used as a return conductor in the ordinary sense, with the transmission voltage equal to the maximum pressure allowable between line and earth and then as the middle wire in a three-wire system with a voltage between the outers equal to double the voltage between earth and either of the outers. On one day, during damp and partially cloudy weather the transmission line was fed with direct current at 20,000 volts and the total leakage amounted to 0.01299 amp., which corresponds to a loss of 0.0866 watt per insulator. When the earth was substituted for one conductor during the ordinary service of the power transmission the drop of volts at the earth plates at Lausanne was observed to be 25 volts and that at St. Maurice 185 volts, the resistance of the earth being negligible.—Lond. *Elec.*, March 18.

References.

Motor-Driven Roller Tables.—Kingsbury.—A full account of tests of motor-driven roller tables at the Duquesne steel works of the Carnegie Steel Company. The object of the tests was to determine data for use in estimating the sizes of motors required in this class of service. The tests were made during the regular operation of the machinery; additional runs were made without loads on the rollers, for determining the no-load friction. The first test was made with a roller table in a 40-in. mill and the second test with a skew table for a 14-in. mill. The article is fully illustrated by diagrams and the results of the tests are given in tables, but it is impossible to abstract them briefly.—*Iron Age*, March 31.

Electric Cranes.—The first part of a fully illustrated paper read before the Vienna Electrical Society on some recent styles of electric cranes. Among them is one which is designed more with a point of view of preventing accidents during lifting or lowering the load than with an intention to get a high current efficiency. As a special feature of the crane is mentioned the use of series motors and series brake magnets which are believed to be more suitable and safer for heavy crane service, since the series motor develops a higher torque for the same current consumption than the shunt motor, while it has the great advantage of automatic speed regulation; that is light loads are lifted more quickly than heavy loads. The series brake magnet is also considered to be better for the purpose of safety. Various constructions of new cranes are illustrated. The article is to be concluded.—*Zeit. f. Elek.* (Vienna), March 20.

Indicator Diagrams.—Concerning the applicability of electrical methods for taking indicator diagrams. (See the abstract on electrical methods for measuring temperatures, under "Units, Measurements and Instruments.")

Traction.

English Electric Railways.—A long editorial review of this subject. The first electric railway in the United Kingdom between Portrush and the Giant's Causeway was opened in 1883. It was built on the third-rail system, but was altered into an ordinary overhead trolley system in 1899. Another short electric railway on the third-rail system was opened at Brighton in 1883 and this is still running. These lines were both very light railways, practically tramways. Two conduit tramway lines were built, one between Gravesend and Northfleet, the other at Blackpool; "but as in the case of many other engineering developments, England took the initiative and then paused, America worked further at the problem and the fully-developed American systems were then brought over to England." The City & South London Railway Company opened the first "tube" line in 1890; in 1893 the Liverpool overhead railway was opened; in 1898 the Waterloo City "tube," and the Central London Railway in 1900. The first steam railway to be electrified was the Mersey Railway, the second is the Liverpool-Southport section of the Lancashire & Yorkshire Railway and the third will be the Tyneside lines of the Northeastern Railway. While the Mersey Railway is self-contained the Liverpool-Southport line, although three times its length, is but one section of the large network of suburban lines owned by the main railway company serving Liverpool. The success of this section will, therefore, mean the electrical equipment of all the other suburban lines of the Lancashire & Yorkshire Railway, so that standardization of track and working voltage was important. A third-rail system was chosen with the third rail outside the running rails and 3 ft. 11½ in. from the center of the 4-ft. 8½-in. gauge. The line voltage was fixed at 600. In the Lancashire & Yorkshire system a fourth rail is employed in the center of the track, but it is not used as a contact rail, being simply bonded to the running rails to decrease the resistance of the return conductor. Three-phase generation and distribution at high pressure is used, with conversion by transformers and synchronous converters to 600-volt direct current in sub-stations. In choosing between direct control and indirect control by means of electromagnetic or electropneumatic switches for several car trains, the company has decided in favor of the former. A double unit system has been adopted with a motor car at each end of the train and two trailers in the middle. This has necessitated the use of no less than eight cable couplings from one end of the train to the other. Two main cables, from auxiliary cables for the series-parallel control, and two cables for working the reversing switches at the motors. There are thus two controller barrels worked by one handle in the cab of each motor car, each barrel controlling the four motors under one of the motor cars. By this method the "contactors" or the electropneumatic devices of the usual multiple-unit systems are dispensed with. (See also the next abstract.)—Lond. *Elec.*, March 18.

English Electric Railway.—The first part of an illustrated description of the electrical equipment of the Liverpool-Southport section of the Lancashire & Yorkshire Railway. This will be the first section of a main-line railway to be worked electrically in England. The distance between Liverpool and Southport is nearly 18½ miles, while the total length of track equipped is practically equivalent to 47 miles of single track. Under steam conditions there are about 36 trains per day in each direction, which will be increased to 65 under electric operation. The running time for local trains, which is 54 minutes with steam traction, will be reduced to 38. The train mileage will be increased from 1,900 to 3,200 per day. Electrical energy is generated as three-phase alternating currents at 7,500 volts and transmitted to sub-stations with step-down transformers and synchronous converters of 650 volts pressure, the maximum voltage at the trains being 600. In addition to some rotary converters at the main power house, the scheme embraces three sub-stations. The generating plant contains four 1,500-kw units and one 750-kw set besides the converters.—Lond. *Elec.*, March 18.

Mendel Road.—Thomann.—The conclusion of his illustrated article on the Mendel Railroad in Southern Tyrol. One part of it is ordinary adhesion road, while the last part of which has very considerable grades, is cable road, one car going always down while another goes up. The cable is operated by a direct-current motor, which is supplied from the same motor-generator which also feeds the adhesion road. This motor-generator consists of a 100-hp, 3,600-volt, 42-period, three-phase induction motor, running at 610 revolutions, and a 60-kw, 650-volt shunt-wound direct-current generator, which is connected in parallel with a storage battery of 324 cells with a capacity of 248 amp.-hours. The high-tension, three-phase currents are transmitted from a hydro-electric plant at a distance of 12 km. The motor which operates the cable is a shunt-wound, 600-volt, 90 to 110-hp, direct-current motor, running at 600 revolutions. Should the car which goes down the mountain carry more than the other one which goes up, the cable motor has a braking effect, since it then acts as generator and sends current into the network. The arrangement of the brakes is described in detail, with the results of tests.—*Eletr. Bahnen*, March, No. 5.

REFERENCE.

Single-Phase Traction.—EICHBERG.—A description, fully illustrated by diagrams and illustrations, of the single-phase traction system on the road from Nieder-Schoenweide to Spindlersfeld, where the Winter-Eichberg motor is used, has been repeatedly noticed in ELECTRICAL WORLD AND ENGINEER.—*Zeit. d. Ver. Deutscher Ing.*, February 27.

WIRES, WIRING AND CONDUITS.

Earth Connections.—MOON.—The first part of an article in which the author points out that a damp situation and a porous soil are not the only necessary conditions required for a good earth connection, but that much depends upon the nature of the soil in which the earth plate is sunk. He gives numerical data on the conductivity of various kinds of soil. He gives some notes on the determination of the conductivity of the soil in a given case. After it has been measured, the resistance of an earth connection can be calculated. He gives the formulæ for special cases and shows that the resistance under the most favorable conditions of an earth plate 2½ ft. square would be about ¾ of an ohm for a plate sunk in the sea, 3 ohms for pure clays, 10 to 15 ohms for mixtures of gravels and clays, and as high as 40 ohms for some mixtures of sands and gravels, or of porous rocks. The least resistance of an earth connection which he has yet measured is 7 ohms, and the mean resistance of a large number of measurements was between 15 and 20 ohms. He gives detailed instructions how to sink an earth plate, and shows that even under the most favorable conditions the resistance of an earth connection is inversely proportional to the dimensions of the plate, and that in many cases it would be little decreased by using a larger plate. A number of small plates, sunk some distance apart, is in any case a more efficient earth connection than one large one; and this is the more so, if the conducting layer of soil is shallow.—Lond. *Elec. Rev.*, March 18.

ELECTRO-PHYSICS AND MAGNETISM.

N-Rays.—Some notes on new properties which N-rays have been found to possess. Blondlot has found that besides the kind of N-rays already described, there exists another kind which reduces the luminosity of a feebly luminous surface instead of increasing it. Bagard has succeeded in reproducing the rotation of the plane of polarization in a magnetic field which was first produced by Faraday in the case of ordinary plane polarized light, and is usually known as the Faraday effect. Since ordinary light consists of waves about 100 times as long as those which make up N-rays, and since according to Faraday the rotation increases as the waves become smaller, it was natural to expect the Faraday effect to be very large in the latter. This has been fully verified by Bagard, who obtained rotations in aluminum and in carbon bisulphide, such as can, with ordinary light only to be obtained in quartz. Blondlot has found a probable explanation of the failure of many other physicists to repeat his observations. It lies in the fact that the emission of light is affected by N-rays in the sense of being concentrated upon the normal rather than upon the tangent plane. Thus an observer watching the surface perpendicularly sees it brighten up while if he watches it along the edge it appears to become duller. In the case of N-rays the reverse is the case.—*Comptes Rendus*, February 29; abstracted in Lond. *Elec.*, March 18.

Demonstrating the Absorption of Radium Radiations.—PASCHEN.—An illustrated note showing that the apparatus of Strutt for demonstrating the positive charge of radium enclosed in a glass tube, may be modified so as to demonstrate also the negative charge of the β radiation which penetrates the glass. As shown in Fig. 2, a glass bottle which may be evacuated contains the small glass tube, *b*, which contains a radium-barium preparation and is suspended by means of the quartz rod, *a*. Two quartz tubes, a_1 and a_{11}, hold the hollow lead vessel, *c*, of a thickness of 2 mm., which is completely insulated from *b*. Through *b* passes in spiral form the platinum wire, *f*, which is connected to the electroscope, *d*. The second electroscope, *e*, is fixed to the lead cylinder. As soon as a good vacuum is reached, both electroscopes diverge, *d* with positive electricity, *e* with negative electricity. It is also possible to demonstrate the current which flows from the interior of the glass tube to the lead cylinder, if both are

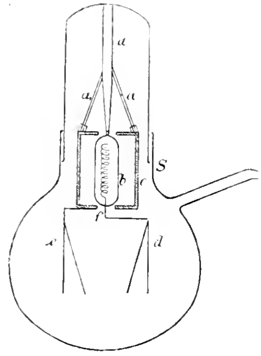

FIG. 2.—ABSORPTION OF RADIUM RADIATIONS.

connected by a wire. This current was first measured by Wien. The divergence of *e* is always smaller than that of *d*, especially on account of imperfect absorption of the β radiation in lead of 2 mm. thickness. Within an hour the electroscopes converge and the charges of their conductors are neutralized, but the neutralization is not complete, both electroscopes showing afterwards a small positive charge.—*Phys. Zeit.*, March 15.

δ-Rays.—A note describing some experiments which Eve has made with Röntgen rays of high penetrating power. Rutherford concludes that Eve's results remove the strongest objection to the view that the δ-rays given out by radioactive bodies are nothing more than an extremely penetrating type of Röntgen rays. It is thus reasonable to expect that these rays are set up as a result of the sudden expulsion of the β particle from the atom of a radioactive body.—From *Nature*, in Lond. *Elec.*, March 18.

REFERENCE.

Electroscope in Vacuum.—PASCHEN.—A note in which he confirms an observation made by Guggenheimer and Korn that two small strips of aluminum, in form of an electroscope, diverge in a vacuum under the influence of light. They believed that the aluminum strips had assumed a positive charge, while the present author thinks that the observation is not an electric phenomenon, but rather due to radiometer action.—*Phys. Zeit.*, March 15.

ELECTRO-CHEMISTRY AND BATTERIES.

Electrolytic Precipitation of Gold.—HAMILTON.—A very full account of the modifications which the Siemens & Halske electrolytic process, as originally worked in South Africa for precipitating gold from cyanide solutions, has undergone in recent years in this country and in Mexico. The main changes are the use of a lead peroxide instead of an iron anode and the fact that the gold is not plated upon the cathode, but is obtained in form of slime, which falls to the bottom. The lead peroxide anodes are practicably indestructible and since there is no compound formed at the anode, like the Prussian blue with iron anodes, they are not covered with canvas. Being indestructible, they do not limit the current density employed. The cathodes are made of tin and are continually kept in the tanks. A good junction between the cathodes and the external conductors is thus rendered possible. The most favorable current density depends upon the amount of gold in solution, the rate of flow of the solution and upon the area of the electrodes. The author gives a full account of measurements which he has made.—*Electrochem. Ind.*, April.

Electroanalysis.—PERKIN AND PREBBLE.—A Faraday Society paper on the electrolytic analysis of gold. They recommend the use of solution of gold salts in ammonium thiocyanate. With a current density of 0.2 amp. per sq. dm. the deposition of 0.05 to 0.08 gram in gold solutions is complete in from 5 to 6 hours. With a current density of 0.4 to 0.5 amp. it is generally possible, even at normal temperatures, to deposit the gold in from 1½ to 2 hours. The appearance of the deposit is generally better when obtained at low current densities and from solutions containing small quantities of gold. For removing the deposited gold from the platinum cathodes, they recommend a solution containing potassium cyanide, with an oxidizing agent such as hydrogen peroxide, sodium peroxide or an alkali persulphate.—*Electrochem. & Met.*, February.

Corrosion of Aluminum.—MOTT.—An article, illustrated by diagrams, on the corrosion of aluminum and its prevention. A film forms over an aluminum anode in certain solutions, such as sodium acid phosphate, and this film greatly decreases the rate of corrosion of aluminum. The author gives results of experiments upon the special protective action of this film, which is many times thicker and chemically different from the ordinary film that form upon aluminum in air. The author thinks that utensils such as aluminum jars, cups, combs, etc., and all kinds of aluminum handles could be coated with this film to advantage. Another field of importance is the treatment of electric lines of aluminum exposed along the sea coasts to the corrosive action of sodium chloride.—*Electrochem. Ind.*, April.

Nickel Refining.—GUENTHER.—An account of successful laboratory experiments on nickel refining. He recommends the use of a sulphate or chloride solution and a somewhat elevated temperature, and a current density of 250 to 275 amp. per sq. meter. The electrolyte is kept slightly acid; the content of free acid—either sulphuric or hydrochloric acid—should be 0.03 to 0.25 per cent. At the cathode more nickel is deposited than is dissolved from the anode; the balance is to be continuously supplied to the bath in form of a concentrate salt solution.—*Metallurgie*, March 10.

REFERENCE.

Gibbs-Helmholtz Equation.—CARHART.—An article in which the author shows that while the Gibbs-Helmholtz principle has been proven to be correct beyond doubt by experiments with various cells, yet the Daniell cell should not be quoted among them, since there are no absolutely correct data for any specific solutions of this cell available.—*Electrochem. Ind.*, April.

UNITS, MEASUREMENTS AND INSTRUMENTS.

Electric Nomenclature.—HOSPITALIER.—The author proposes for discussion the following suggestions: He wants them to be taken up by the general body of members of the International Electric Congress in St. Louis, but not by the board of official delegates (which he calls the Senate of the Congress). A physical quantity defined as the quotient of two other quantities gets its name from the numerator in combination with the name of the denominator, the latter in adjective form. A physical quantity defined as the product of two other quantities gets its name by combining the two quantities together and joining them by a hyphen; thus, force-length is work. The following adjectives are proposed: linear for length, surfacic or sectional for surface, volumic for volume, massic for mass, temporic or chronic for time, poweric (puissancique) for power, ergic for energy or work. The symbols in the physical formulæ should be printed in italics, or Greek letters, while the abbreviations or units should be printed in Roman characters. The table of symbols and of abbreviations recommended by the Board of Delegates of the International Electric Congress of Chicago in 1893 and printed as a supplement to the *Proceedings* of this Congress, should be revised, completed and adopted as a table of international symbols and abbreviations for the principal physical and electrical quantities and units. For alternating currents he would suggest the following terminology: active current for what we now call the energy component of the current; imaginary current for what we now call the energy component of the current; imaginary current for what we now call the wattless component of the current; and correspondingly, active power and imaginary power.—*L'Industrie Elec.*, March 10.

Electrogoniometer.—CHAUMAT.—A paper read before the International Society of Electricians in Paris on an instrument of Routin for measuring the phase difference between e.m.f. and current in a three-phase system. The method is a zero method, one e.m.f. u_1 in phase with the current being opposed by another u_2, equal to the former and variable with one of the tensions of the three-phase system, E (Fig. 3). The angle e represents the phase difference to be determined. The principle of the method is indicated in Fig. 4. One essential part of the apparatus is a transformer, the primary of which is in series with the phase $A\,O$ of the three-phase system, while the secondary is shunted by a non-inductive resistance; the tension at its terminals is u_1. The second essential part is a device, called decaleur, which is connected on one side to the three phases of the three-phase system, and which produces at the other side the tension u_2, opposed to u_1. Two hot-wire voltmeters, V_1 and V_2,

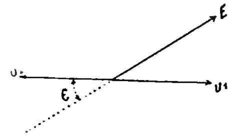

FIG. 3.—MEASURING PHASE DIFFERENCES.

of different sensitiveness, enable one to estimate one-tenth of a volt, which represents an accuracy corresponding to one-third degree for the angle of phase to be measured. The transformer has a primary

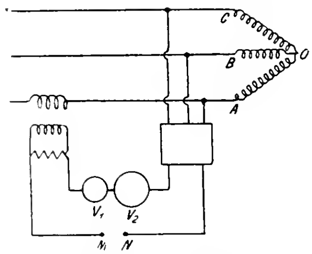

FIG. 4.—DIAGRAM OF CONNECTIONS.

with four coils, each of 25 turns, and permits the use of a current of 25 amp.; the secondary has 1,800 turns. For a phase difference smaller than 1°, the absorbed power is 1.1 watt. The principle of the "décaleur" is shown in Fig. 5, in which $O\,A$, $O\,B$ and $O\,C$ represent by their length and direction the three e.m.f's of the three-phase system. If an insulating rod, $m\,n$ (of a length equal to $O\,A$)

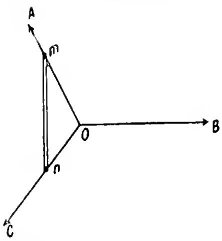

FIG. 5.—DIAGRAM SHOWING PRINCIPLE OF "DÉCALEUR."

is moved with its terminals, m, along $O\,A$ and n along $O\,C$, then the potential difference between m and n is constant, but its phase varies. In this way it is possible to make the phase of u_2 opposite to that of u_1. In practice, this rod, $m\,n$, is moved on a drum with a large number of turns.—*La Revue Elec.*, March 15.

Electrical Methods for Measuring Temperatures.—CALLENDAR.—A note on his concluding lecture on this subject. He demonstrated the applicability of electrical methods for taking indicator diagrams. For this purpose a motor scale had been rigged up in the lecture room and five thermo-couples had been screwed from the outside into the central wall of its small internal combustion engine. Since the thickness of the cylinder casing is about ⅛ of an inch, the temperature indications of the thermo-couples could be taken to represent also the internal temperatures. One couple was placed near the exhaust, another near the inlet and the remaining three were fixed near the top, the middle and the bottom of the stroke, respectively. First he determined the temperatures at these various points. He proved experimentally that the temperature at the exhaust side of the cylinder was considrably higher than at the inlet side, but that, by directing a blast of air from a small fan against the exhaust, this order of things might be reversed and the engine rendered more powerful in consequence. The measurement of the temperatures at the three points of the stroke brought out the fact that these temperatures—contrary to expectation—differed but little, the explanation being that the heat generated in the combustion chamber was rapidly transported to all points of the stroke by the piston. The indicator diagrams which were taken were perfectly continuous at the very highest speeds (about 2,000 r.p.m.) and with their aid the influence of a retarded or advanced spark and of various compositions of the gaseous mixture could be easily studied.—Lond. *Elec.*, March 18.

New Books.

DIE HERSTELLUNG VON METALLGEGENSTANDEN UND DIE ELEKTROGRAVURE. By Dr. W. Pfanhauser. Halle: Wilhelm Knapp. 146 pages. Price, 7 marks.

This volume is the fifth one of the series of monographs on applied electrochemistry, edited by Victor Engelhardt and published by the well-known electrochemical publishing house of Wilhelm Knapp. Its author, Dr. W. Pfanhauser, is a recognized authority on the subject and the author of several other books on galvanotechnics. In the present volume, after a brief historical introduction, he takes up the discussion of the composition of the copper plating bath, as being the most important representative of the galvanotechnic baths. The results obtained by different investigators are summed up, the influence of concentration currents, etc., is investigated, and the maximum current densities allowable under various conditions are given. Then follows an interesting chapter on the physical properties of the deposited copper, with data of tests for tensile strength, etc. The next chapter deals with the question of the anode copper, and in the following two chapters brief data are given on the bath constants, the deposits and the calculations of the latter, and the arrangement of electroplating establishments. Then follows a compilation of the methods used for the purpose of obtaining even deposits, especially on curved and irregular surfaces, and the methods for removing the deposits from the cathode. In the following chapters are grouped together in the order named, the methods for the manufacture of metallic powders, metallic foils, wires, vessels of various forms, parabolic mirrors and tubes. The next chapter is devoted to electrolytic etching and the last chapter contains a description of Josef Rieder's method of electroengraving. The latter method consists essentially in arranging a steel disc, serving as anode, on top of a block of gypsum, which projects above the surface of the electrolyte. The contact surface of the block is shaped in the form it is proposed to give to the lower surface of the steel disc. The electrolytic vessel is filled with a solution of ammonium chloride, and as the block of gypsum becomes saturated with the latter solution, electrolysis takes place at the contact surface of the block with the iron. As a result, the steel disc is dissolved out corresponding to the shape of the top of the gypsum block on which it rests.

The book is an interesting and valuable contribution to the literature on the subject, the numerous references to journal and patent literature being specially noteworthy. Though the treatment of the various matters dealt with is necessarily brief, the author has succeeded in bringing out clearly the important points, and he has thus been enabled to present a comprehensive review of the state of the art at the present time.

AUFGABEN AUS DER ELEKTROTECHNIK NEBST DEREN LÖSUNGEN. By Dr. Phil. E. Müllendorff. Berlin W.: Verlag von Georg Siemens. 113 pages, 14 illustrations. Price, 2.50 marks.

This small book of problems for the electrical engineer, with their solution, ostensibly attempts to cover the ground recently traversed by Prof. Atkinson in his "Electrical and Magnetic Calculations." The spirit in which Müllendorff has approached his task is indicated in his preface by the words, "It must be conceded that, for electrical engineers, the vital connections between theory and practice are difficult. The pronounced failure of the modern higher instruction in technical studies is that it leads to no practical applications. Many problems whose solution seems simple when presented in the course of instruction, develop unexpected complications and difficulties when applied in subsequent practice." Such an expression on the part of an author would lead one to surmise that he had not vitally grasped the place and significance of electrical theory, and its real relations and applications in practice; and that a lack of thoroughgoing knowledge of such subjects had led him to place an unwarranted emphasis on certain phases of theory, such as that of the transformer; and that he had perused the older academical methods, rather than the later processes of analysis which are inseparably associated with practice. These assumptions are abundantly borne out by the context. Prof. Atkinson has wisely discriminated in his book between a manual for the solution of problems and a text for the derivation of formulas. Müllendorff has confused the two, and sacrificed the unity of his book. In the selection of matter, Prof. Atkinson has broken away from the old and perhaps classical academical problems, and presented only those cases which have an actual application in engineering practice. In this later work the author seems to have gone over the ground anciently cultivated by Cumming and similar writers.

The opening chapter deals with the problems of the absolute system of units. The second chapter seems wholly out of place in a work of this character. Here the writer attempts a numerical exposition of the theory of potential, a subject which belongs properly to such a work as Webster's, intended for electrical physicists. One meets here the mechanics of the Newtonian potential theorem, whose vital application in practice is remote. In the sixth chapter, given to miscellaneous problems, a brief summary is presented of Kelvin's method in line and station economics, which might profitably have been extended to a more adequate discussion. In the chapter devoted to the technics of alternating currents, the usual academical subjects are attempted and their treatment is purely that of analysis. Here, as in general throughout the book, the differential equation is taken for the departure of the discussion and solution. The matter and method are those of the purely analytical discussion of periodical functions; these, however, are conscientiously worked out, and should prove interesting and suggestive. The concluding chapters deal with vector analysis, methods of least squares, and transcendental functions. Thus the book is a pure mathematical and academical summary of the theory of electrophysics, and its matter and treatment are very distantly related to its title and purport.

While Prof. Atkinson's book is representative of American methods of practical instruction, the book of Müllendorff cannot be accepted for German pedagogy. Though German methods of discussion are in the main more obscure and not so clearly directed as American, yet they are far in advance of those presented in this book. There is a certain humor in mathematics which should save the worker from expending pains to obtain the third decimal place, when the first is doubtful; and this humor should dispel the presumptive gravity of a formidable algebraic array of manipulations with capacity and self-induction of copper conductors in air, when their applications are so generally associated with the obscurities and uncertainties of dielectrics and iron.

Müllendorff's book lacks wholly this sense of humor; it lacks also unity of treatment and the true engineering sense, probably because we have here an academician writing for an electrical engineer. The book may prove useful and interesting as a summary of certain academical methods and processes.

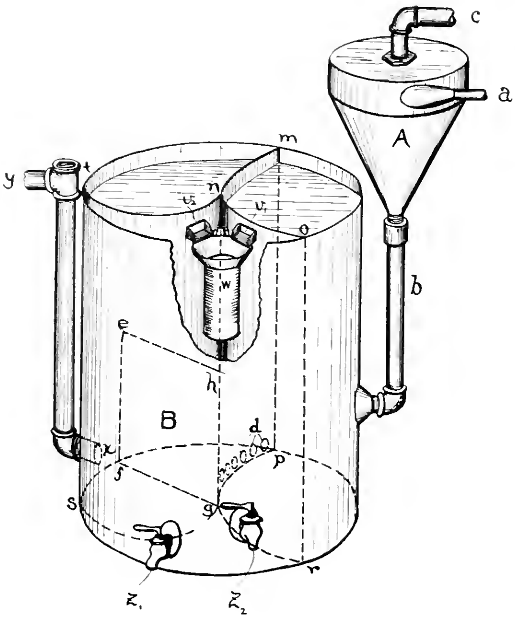
Recovery of Cylinder Oil.

By Thomas Griswold, Jr.

A successful, and so far as the writer knows, an original method for the recovery of cylinder oil is practised at the Midland (Mich.) plant of the Dow Chemical Company. A brief description of the means employed may interest central station men and others engaged in economical power production.

The recovery apparatus which we call a "skimmer" is applied to a vertical cross-compound, direct-connected generating unit of 1,600-kw capacity. The engine cylinders are provided with valves in the heads, and are connected by a large intermediate receiver drum without reheating coils. This receiver is at one side and below the cylinders, so that condensation collects in it and must be removed by a trap. Having noticed that the water discharged by the trap was yellow with oil which rose on standing, we first connected up a series of three oil barrels in cascade, letting the discharge enter the first or highest one tangentially near the bilge. This caused a cyclonic action separating the steam and water, the latter falling to the bottom, the former being led away at the top to an open feed water heater. The water was piped from the bottom of the first barrel to the middle of the third by a pipe. The third barrel had an overflow connected with the bottom. The different parts were so arranged that the second and third barrels were kept nearly full of water. We found that about 95 per cent. of the oil rose to the surface in the second barrel and that there was very little oil left in the discharge which passed the third barrel. This outfit, although successful, was not sightly, nor was it cleanly, but it served to demonstrate that by allowing the water to stand quiet for a few minutes a large percentage of oil could be recovered. After skimming a number of gallons and allowing it to further settle and clarify, we strained it and used it again in the same engine with success.



OIL SKIMMER.

The sketch herewith shows in a diagrammatic way the "skimmer" made to replace the barrels. The device consists of a steam and water separator, A, and an oil and water separator, B. The trap discharge enters A tangentially at a, where the water separates by centrifugal force and falls to the bottom, flowing to B through the pipe, b. The steam is led away to the heater through the pipe, c. B is divided into three parts by vertical cylindrically-formed partitions. The parts o, n, m, p, q, r and m, n, t, s, g, p are water compartments connected through the holes at d. The latter compartment is also partially divided by a partition, f, e, h, g, designed to cut off the water about the discharge, x, from disturbing effects due to circulation. The compartment, o, n, t, s, g, r, is for the skimmed oil, which, after it has accumulated to a certain extent on the surface of the water in the other two compartments, flows over the weirs at v_1 and v_2 into the screen or strainer, w. The height of the overflow, y, is regulated to permit the oil to accumulate to a depth of about 8 in. before it rises to the weirs. It is kept fluid by the hot water underneath, and the larger part of the water separates out before it begins to "skim." The oil compartment being bounded on two sides by hot water is also kept warm and the water still further separates there, where it may be drawn off at the faucet, Z_1. The recovered oil is finally drawn at Z_2. The skimmer is also provided with a cover, not shown, and the screen, w, is removable for cleaning.

The action of this device is quite automatic and it seems to recover practically all of the high-pressure oil fed to the engine. The recovered oil appears substantially like that originally fed, and so far seems to answer as well on refeeding. The discharge water is still somewhat yellow, and on agitation with a suitable solvent shows oil in small amount. It seems probable that this lost portion may be largely one particular constituent of the oil as originally compounded, and that eventually the repeatedly recovered oil may lose its "quality" and be fit only for low-pressure oil or for other less important purposes of lubrication where the high-pressure grade is not required.

Storage Battery Installation at Binghamton, N. Y.

An interesting storage battery installation illustrating the handiness of the storage battery for isolated plants has just been made in the power house for lighting and heating, which serves the Broome County buildings at Binghamton, N. Y. The plant as first installed was operated with live current and included a 10 x 9 Westinghouse Junior engine, direct-connected to a 37½-kw Westinghouse 110-volt, direct-current generator. As a matter of fact, however, while this plant was entirely satisfactory, it was found cheaper during the hours of limited lighting to burn gas rather than start up the plant. Under these circumstances in order to get the best possible service out of the installation, it was decided to add a storage battery and the contract was awarded to the Smith Storage Battery Company, of Binghamton, N. Y., for one of their novel and ingenious horizontal tray type batteries. The installation as it now stands equipped is shown in the cut herewith.

The addition to the plant consists as shown of 56 elements of the tray type of 280 amp.-hour capacity, together with a battery panel addition to the original switchboard, this new panel being provided with the necessary switches, voltmeters and ammeters, circuit-breaker and voltage regulator.

STORAGE BATTERY INSTALLATION, BINGHAMTON, N. Y.

The battery is arranged in two piles of 29 trays, each 22 x 48 in., entirely enclosed in glass, something after the manner of a glass showcase, so as to reduce evaporation and exclude dust. The whole presents an extremely neat, simple and workman-like appearance. The result is that no gas is now used in the buildings, and that while the engine during the winter season is only run about five hours a day, there is electric lighting service for 24 hours per day. It is estimated by the Board of Supervisors, to whom the credit is due for this change, that an investment of $10,000 is saving the county about $2,000 a year. This is but one case out of a great many where the storage battery finds a definite function and plays a very useful part.

Data on the Marconi Wireless Telegraph System.

The annual report of the British Marconi Company gives a variety of interesting data, some of which has been published: The Italian Government has been very active in the extension of wireless telegraphy throughout Italy. A number of stations have been erected during the past year which are available exclusively for the use of ships equipped with the Marconi system through the continuous support and assistance of the government of the King of Italy. The site for a high power station, near Pisa, for communicating with the Argentine Republic, and with the company's high-power stations in the United States and Canada, has been selected by Mr. Marconi, and some of the plant for this station is already on order. Arrangements have also been made for a wireless telegraph service between Italy and Montenegro, in the benefits of which the Marconi Company participates. Negotiations have for some time past been going on between the company and the board of trade for the equipment of lightships with wireless telegraph apparatus, and a contract relating to this service is in preparation.

During the year negotiations with a group of Danish financiers were entered into for the connection of Iceland with Europe by wireless telegraphy, that country being at present isolated from the world so far as telegraphic communication is concerned. The negotiations are at present temporarily suspended, partly owing to the inability to obtain from the English post office the facilities for an inland service which are necessary, and partly to other difficulties.

Fifty-four shore stations are now installed commanding the principal shipping routes, these stations being available exclusively for communication with ships equipped with the Marconi system. Among them are stations worked by the British Admiralty, the Italian Admiralty and Lloyd's. As the stations worked by the governments and Lloyds are increased, an extension of the arrangements for working exclusively with ships equipped with the Marconi system will ensue.

Launch Motors and Controllers.

One of the features of the St. Louis Exposition will be the operation of a number of electric launches upon the waterways somewhat in the same manner as at Chicago and the Buffalo Pan-American. The Hertner Electric Company, of Cleveland, Ohio, has recently

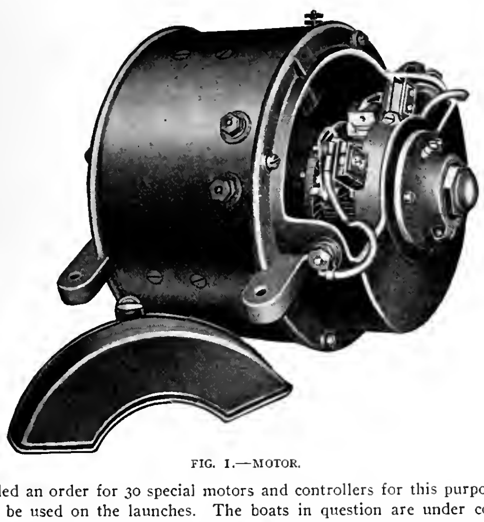


FIG. 1.—MOTOR.

filled an order for 30 special motors and controllers for this purpose, to be used on the launches. The boats in question are under construction by the Truscott Boat Manufacturing Company, of St. Joseph, Mich., and each will seat about 30 persons. Current will be furnished by storage batteries, a 140-amp.-hour, 88-volt Willard battery being furnished for each equipment. As in the case of most of the recent gasoline boats, the motors are of the automobile type and are those built ordinarily by the Hertner Company as their standard 2½-hp for automobile purposes. They are illustrated in Fig. 1 and are multi-polar with forged steel field yoke and laminated poles. Ball bearings are provided so constructed as to take care of end thrust as well as radial pressure. Special heads are used so that the motors are water-tight up to the level of the bearings; the upper half of the front head being left open so as to expose the commutator and brushes, over which a removable cover is provided. The motors are compound wound and designed for high efficiency. The controllers shown in Fig. 2 are arranged for three forward and

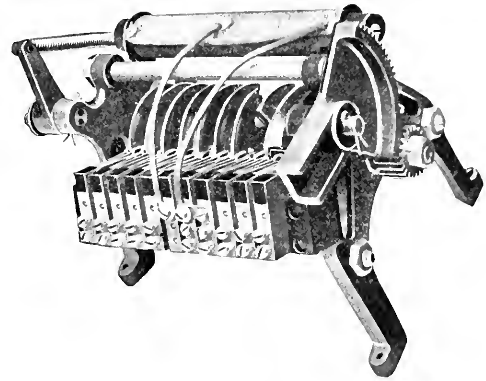

FIG. 2.—CONTROLLER.

two reverse speeds. The first speed forward is on 44 volts with a resistance in series with the armature. The second speed cuts out the resistance. This yields the ordinary rate of running at about 4½ miles per hour when the motor makes 600 r.p.m. For emergencies, the battery is thrown in series, when the motor operates on the full 88 volts and the speed of the boat is hit up to about 6½ miles. The backward speeds are on the 44 and 88 volts, corresponding to the second and third speeds forward. When the controller handle is in the off position the battery is series-connected and can be charged from a regular 110-volt circuit. Exhaustive tests have been made on these equipments, resulting in the St. Louis contract.

Rubber Compound for Electrical Purposes.

A new insulating material has recently been put upon the market by the Electric Rubber Manufacturing Company, which is intended to take the place in some degree of full rubber for the production of battery jars and other purposes. The company named has an adulterant for pure rubber which serves as a substitute for from 25 per cent. and upwards, according to the article required, and which it is said is fully as efficient, although with pure Para rubber costing from $1 to $1.40 a pound, the adulterant can be sold for 12 cents a pounds. With regard to this material, a sample of which made up in a resilient battery jar has been shown us, tests and analyses are submitted by Prof. A. F. Ganz, of the Stevens Institute of Technology, and Mr. W. J. Comly, an electrochemist of New York City. Speaking of the sample submitted to him resembling vulcanized rubber and in the form of a plate measuring 14½ x 11½ x ¼ in., Prof. Ganz states that the insulation resistance determined was greater than 50,000 megohms. Dr. W. E. Geyer, after testing insulated wire with the same compound applied to it and having a thickness of vulcanized insulation of .071 in. on a copper wire of .039 in. diameter, stated that the insulation resistance on one minute electrification at 68° F., after four days immersion in water, was 350 megohms per mile. The capacity per mile was 0.677 microfarad. The resistance to rupture in a length of about 100 ft. tested by means of alternating current was shown by a rupture occurring at 7,000 effective volts. This insulation would appear to have been vulcanized for 40 minutes at 270° F. Other tests are quoted together with the report of Mr. Comly on the resilient battery jars, which stood up under severe tests with sulphuric acid, caustic potash, etc. Some of these jars are reported to have been in use by Altman & Co., in New York City, in their automobile delivery wagons with satisfactory results.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—The stock market was strong in tone but there was slackened activity. The harmonious situation in the settlement of the Northern Securities matter had a good influence, yet it did not attract any great outside public interest. The principal incident of the week was the large purchases of Union Pacific common, supposed to be by Standard Oil financiers, who are interested in the St. Paul road. The Easter holidays created dullness toward the end of the week, and trading became decidedly professional. There was an inclination to accept a cheerful view about iron and steel trade conditions and prospects, and the current belief is that the United States Steel directors will this week declare the regular 1¾ per cent. dividend on Steel preferred, even though the earnings for the March quarter fall to around $10,000,000, as compared with some $25,000,000 for the same three months last year. Steel shares and the second mortgage 5 per cent. bonds of the corporation were decidedly strong. The easy money market was a supporting element in the stock market. The electric and traction securities showed a firmer tone and better prices were secured, all closing with net gains except General Electric, which lost 1⅜ points, closing at 164⅝. Allis-Chalmers preferred was steady at 40, an advance of ½ point. The greatest gain was in American Telephone & Telegraph, which ruled at 124¼ throughout the week, this being also the closing figure and a gain of 4¾ points. Brooklyn Rapid Transit and Metropolitan Street Railway both made a net gain of ⅞ point, the former closing at 44⅛ and the latter at 111⅞. Western Union closed at 88½, thus making a net gain of ¼. Westinghouse Electric closed at 159 ex.-div. The curb market was generally firm, with a reduced volume of business. There was an active demand in Interborough Rapid Transit, which brought about a rise of several points in that stock in the anticipation of the early opening of the subway. This event, however, will not occur, according to a statement from Mr. McDonald, until August, or later, depending largely upon the attitude of the labor organizations during the summer. Below are given the closing quotations of April 5. In Boston stocks were generally quiet on account of the holidays. Massachusetts Electric lost ¼ point. The market was quite devoid of features.

FRANCHISE VALUATIONS.—Special franchise valuations in New York City, as computed by the State Tax Commissioners, and on which the corporation franchise tax is levied, increased $16,363,725 over the aggregate for the previous year, the grand totals being respectively $235,157,725 and $251,521,450. In a number of instances the valuations were lower than the previous year, but in the majority of cases, where changes were made the valuations show an increase. The new corporations receiving franchises in 1903 number but 10, and the total valuation of their franchises is but $16,300. This leaves the net increase in 1903 in the old companies $16,347,425. The largest increases is that of the Consolidated Gas Company, of New York, being $3,917,000, and the greatest reduction was in New York Telephone (Manhattan branch), $239,000. The larger of the increases are: New York Edison Company (Bronx), $70,000, and (Manhattan), $1,965,000; New York Mutual Gas Light Company, $251,500; United Electric Light & Power Company, $315,000; Empire Subway, $546,000; New York & New Jersey Telephone Company (Brooklyn), $428,000, and (Queens), $40,000; Brooklyn City & Newtown Railroad, $84,000; Bleecker Street & Fulton Ferry Railroad, $115,000; Christopher & Tenth Street Railroad, $100,000; Metropolitan Street Railway, $67,000; Union Railway (Bronx), $188,000; New York & Queens County Railroad, $70,000; Consolidated Telegraph & Electrical Subway, $733,000; Manhattan Railway, $2,600,000; Edison Electric Illuminating Company, Brooklyn, $1,034,000; New York Telephone Company (Bronx), $43,000; Western Union Telegraph Company, $30,000; Brooklyn City Railroad Company, $260,000. The largest of the decreases are: Brooklyn Union Elevated Railroad, $141,000; Dry Dock, East Broadway & Battery Railroad, $50,000; Forty-second Street, Manhattanville & St. Nicholas Avenue Railroad, $70,000; Long Island Railroad (Brooklyn), $55,000; Brush Electric Illuminating Company, $36,000.

THE MACKAY COMPANIES.—The Mackay Companies have declared a quarterly dividend of 1 per cent. upon the preferred stock, payable April 9 to stock of record March 31. Stockholders of the Commercial Cable Companies were given two shares of Mackay Companies preferred stock and two shares of common for each share of Commercial Cable. The Commercial Company pays 8 per cent. per annum to the Mackay Companies, which distributes it in preferred stock dividends. There were about 900 stockholders of the Commercial Cable Company. A large majority of the stock of the Cable Company has been exchanged for stock of the Mackay Companies. The time for the deposit of this stock with the Old Colony Trust Company, Boston, and Manhattan Trust Company, of New York, has been extended to and including April 18.

CHICAGO CITY RAILWAY CO. shows the following statement for the year 1903, to December 31:

	1903.	1902.	1901.
Gross	$6,435,565	$6,413,181	$5,900,000
Expenses	4,648,341	4,336,504	4,142,841
Net	$1,787,224	$2,076,677	$1,757,159
Depreciation	100,000	180,000	....
Balance	$1,687,224	$1,896,677	$1,757,159
Dividends, etc.	1,619,991	1,620,000	1,630,000
Surplus	$67,233	$276,677	$127,159

BELL DIRECTORS.—At the annual meeting the following directors of American Telephone & Telegraph Company were re-elected; Charles W. Amory, George F. Baker, Francis Blake, Charles P. Bowditch, George L. Bradley, Alexander Cochrane, T. Jefferson Coolidge, Jr., John D. Waterbury, Moses Williams, W. Murray Crane, Frederick P. Fish, Henry F. Howe, Charles Eustis Hubbard, Charles E. Perkins, Thomas Sanders, Nathaniel Thayer, Theodore M. Vail. Thomas B. Bailey was elected a director to succeed J. Malcolm Forbes.

DIVIDENDS.—The Westinghouse Electric & Manufacturing Company has declared a quarterly dividend of 2½ per cent. on preferred and assenting stock payable April 11. The Electric Storage Battery Company has declared a dividend of 1¼ per cent., payable April 1. The Binghamton (N. Y.) Railway Company has declared a dividend of 2 per cent., payable April 11. The Mackay Companies have declared a quarterly dividend of 1 per cent. on the preferred stock.

SNOQUALMIE FALLS POWER.—It is stated in Seattle (Wash.) dispatches that the Snoqualmie Falls & White River Power Company, with $3,000,000 capital, has acquired the property and business of the Snoqualmie Falls Power Company, the White River Power Company, the Seattle Cataract Company, and the Tacoma Cataract Company.

SALT LAKE CITY, UTAH.—A contract has been entered into between the Salt Lake Railroad Company and the Western Union Telegraph Company, which gives the latter corporation wire privileges and the right to handle all commercial telegrams along the line of the new railroad.

HUDSON RIVER TELEPHONE.—The Hudson River Telephone Company reports a gross for the year ended December 31, 1903, of $883,885, increase $96,555; net, $269,852, increase $33,288; surplus after charges and dividends, $18,572, decrease, $19,464.

ELECTRIC LIGHTING COMPANY EARNINGS.—Messrs. Stone & Webster report the earnings of the following companies for the month of January, 1904:

TERRE HAUTE ELECTRIC CO.

	1904.	1903.	Inc.	Dec.
Jan. gross	$41,188	$33,535	$7,653	....

Commercial Intelligence.

THE WEEK IN TRADE.—The wet weather is still throttling trade. "Low temperatures, heavy rains, bad roads and floods, the latter in the Ohio and tributary valleys," *Bradstreet's* notes, "have checked spring trade, delayed collections, discouraged Easter demand and closed a three-months' period of rather backward business in the North, East and West." While this report seems rather discouraging on its face there are some redeeming features. Agricultural implement men are doing well and have done what is probably their best season's trade on record. The railroads, too, are better off, and are gradually getting the upper hand in the transportation difficulties. In the South wholesale trade was never better than it is at present, and the feeling in the iron and steel trades is of a much more cheerful character. The agricultural situation is very satisfactory, and large yields are looked for. An enormous cotton acreage will be planted. Dry goods distribution is behind last year at all the leading markets. Textile machinery is not running full and the demand for cotton goods is backward, high prices being a bar to activity. The trade outlook on the Pacific Coast is good, notwithstanding the unfavorable weather conditions there. In the iron situation the outlook is satisfactory. Furnaces are filled up with orders for the second quarter, and prompt deliveries of pig iron and billets are being extensively demanded. There is a good call for finished products, effects of labor troubles being noted in structural material, however. Large tunnel work and pipe contracts are expected to call for an immense quantity of iron. Copper was notably strong. Lake and electrolytic are quoted at 12¾c. to 13c. and casting stock at 12½c. to 12¾c. The business failures for the week ending March 31 numbered 212, according to *Bradstreet's*, against 215 the previous week and 145 the corresponding week last year.

PRODUCTION OF MICA IN 1902.—A report on the production of mica in 1902 by Dr. Joseph A. Holmes, abstracted from the annual volume of Mineral Resources, published by the United States Geological Survey, shows that the total quantity of mica produced in the United States during the year 1902, as reported to the Survey, was as follows: Plate mica, 373,266 pounds, valued at $83,843; scrap mica, 1,028 short tons, valued at $13,081, and mica rough as mined, or unmanufactured, 372 short tons, valued at $21,925; making a total value of $118,849. The increase in the production of plate mica during the last three years is due to the increasing quantity of small-sized mica discs and rectangular sheets that have been cut for electrical purposes. During 1902 there was a large falling off in the production of scrap mica, which in 1902 amounted to 1,150 short tons, valued at $14,606, as against 2,171 short tone, valued at $19,719 in 1901. The tables which show the great increase in the importation of mica during 1902 are significant. This increase, valued at $131,278, is larger than the total value of the product of mica in the United States during 1902. It illustrates the increasing demand for mica in this country. Although mica is widely distributed in the United States, actual mining has been limited, during the last few years, to North Carolina, New Hampshire, South Dakota, New Mexico, Idaho, Virginia and Colorado. Some development work has also been carried on in California, Nevada, Maine, Alabama and Georgia.

NEW YORKERS IN CONTROL OF MONTEREY PLANT.—The firm of J. G. White & Co. and the Wall Street banking house of N. W. Halsey & Co. have acquired control of the Monterey Electric Light & Power Company, which operates an extensive plant at Monterey, Mexico, for lighting and general power purposes. The Monterey Light & Power Company has been incorporated under the laws of the State of New Jersey with a capital of $500,000. P. G. Gossler, formerly general manager of the Montreal Light, Heat & Power Company, and now head of the operating department of J. G. White & Co., has been elected president; Robert Lewis Hoguet, of the law firm of Hornblower, Byrne, Miller & Potter, is vice-president, and Harry R. Tobey, of N. W. Halsey & Co., is secretary and treasurer. The directors are Mr. Gossler, Chester Griswold, treasurer of J. G. White & Co.; Roger H. Williams, of N. W. Halsey & Co., and Morris K. Parker, of the same firm. The plant is to be remodeled and considerably enlarged. About 1,000 kw of additional equipment has been ordered. There will be a 500-kw Curtis turbine. Two 240-kw belt-driven alternators, one 125-kw engine-driven exciter generator and two 7½-kw belted exciter generators, transformers, etc., have also been ordered from the General Electric Company. One hundred and fifty General Electric fan motors will also be shipped. The boilers will be Babcock & Wilcox.

PEARSON SYNDICATE TO SUPPLY POWER TO EL ORO.—The Mexican Light & Power Company, Limited, has determined to transmit power to El Oro—one of the most extensive mining camps in the southern republic. The current will be generated at the Necaxa plant, which is now being hastened to completion. This plant is to have an initial capacity of 45,000 hp, the equipment consisting of Escher-Wyss turbines, Siemens & Halske generators and General Electric transformers. Later on it will be equipped with further machinery, which will bring up the development to no less than 80,000 hp. The use of electricity at El Oro will permit of the working of several low-grade mines now lying dormant owing to the prohibitive cost of steam power. It is estimated that electric current can be furnished at less than half the cost of the existing means of operation. Primarily, it was the intention of the Mexican Light & Power Company, in which F. S. Pearson is one of the leading spirits, to furnish current for use in Mexico City and vicinity. The extension of the transmission lines to El Oro, representing a total of about 175 miles, will make the system one of the largest in the world.

EQUIPMENT FOR A BRICK FACTORY.—The Schwarz System Brick Company, 8-10 Bridge Street, New York, has just installed at Charleston, S. C., the first brick plant in this country to be electrically operated throughout. The initial capacity of the equipment is 75 hp, but it will be considerably added to in the near future. The generator is a 50-kw, 250-volt, 850-r.p.m. machine built by the Northern Electrical Manufacturing Company, of Madison, Wis. It is belted to a 75-hp horizontal engine built by the Houston, Stamwood & Gamble Company, of Covington, Ky. Two Northern motors of 22-hp and 10-hp capacity, 220 volts, are used for operating the elevators, lime crushers, preparing machines and brick press.

CONDUIT FOR CINCINNATI SUBURB.—Mr. G. M. Gest, the expert subway contractor of New York and Cincinnati, Ohio, has just been awarded a contract by the Bell Telephone Company, of Cincinnati, for installation of a large conduit system through Cumminsville, one of the outlying districts of that city. Work is to be started immediately.

NAVAL ELECTRICAL SUPPLIES.—The Bureau of Supplies and Accounts, Navy Department, Washington, will receive bids until April 26 for the following supplies for the Portsmouth, Boston and New York Navy Yards: One 24-in. electrically-driven engine lathe; one electrically-driven deck winch; seven 20-hp electric motors.

SALE OF LIGHTING PLANT.—The Milford Electric Light and Power Transmission Company, of Milford, Ill., has been sold through the agency of J. S. Maurer & Co., to Mr. E. Lindner, of Pecatonica, Ill., for $15,000.

BALL ENGINE CONTRACT.—The Ball Engine Company, Erie, Pa., has been awarded a contract for three 225-hp direct-connected engines for the Seelbach Hotel, of Louisville, Ky.

LARGE EXPORT TRADE.—United States domestic manufactures exported in February, 1904, were greater in value than in any preceding February, and formed also a larger per cent. of the total exports than in any preceding February. For the eight months ending with February the total manufactures also exceeded the total in the corresponding eight months of any earlier year. The fiscal year 1900 was the banner year in exports of manufactures from the United States, but from present indications the fiscal year 1904 will show an even larger total of manufactures exported. The month of February shows a total of thirty-eight million dollars' worth of manufactures exported, against thirty-four million dollars in 1900, while for the eight months ending with February the total is two hundred and eighty-eight millions, against two hundred and sixty-eight millions in the same months ending with February in 1900. These figures, which are presented by the Department of Commerce and Labor through its Bureau of Statistics, indicate pretty clearly that the fiscal year 1904 will show a larger total of manufactures exported than any preceding year. In the eight months for which a record is already made the total exceeds by twenty millions that of the highest record previously attained, that of 1900, while the fact that February, 1904, exceeds by four millions the figures of February, 1900, also indicates that the increase noted in the earlier months of the year is continuing in the latest available months and thus likely to carry the year's total considerably beyond that of 1900. Details as to electrical apparatus are not yet forthcoming, but scientific instruments, including smaller electrical goods show an increase in the eight months from $4,647,940 to $5,935,808.

WAR DEPARTMENT ORDERS 120 BOATS.—The Electric Launch Company of Bayonne, N. J., has just received an order from the United States War Department for 120 boats for the artillery corps' use in planting submarine mines. The boats will be capable of handling 500 mines, and will be used as tenders to the new submarines now building. This is the largest boat order in numbers ever placed by the department, and was obtained by the builders under competitive bidding with all the leading manufacturers of the country. The boats, if placed in line, would equal nearly a half mile in length. Over 30,000 feet of the best boat cedar and 32,000 feet of ship oak will be used in their construction. A ton of copper nails and rivets will be required to fasten the timber together. The boats are now building and will be all completed on June 30, 1904. Charles G. Gates, of New York, has placed an order with the Electric Launch Company for a 23-foot electric yacht tender for use on his yacht "Charmary." The tender will be of the navy type of light weight, with capacity of operating forty sea miles on one charge of the battery. It is the same type that the United States Navy Department has recently purchased, and which are in use on the U. S. S. *Mayflower*, U. S. S. *Florida*, U. S. S. *Dixie* and other warships.

MORE C. & C. MOTORS FOR HAMBURG-AMERICAN DOCKS.—The C. & C. Electric Company, 143 Liberty Street, New York, has secured a further order—the seventh—for 35-hp motors to be installed on the Hamburg-American docks at Hoboken, N. J. The motors will be direct-connected to hoists built by the Consolidated Iron Works, of Hoboken. This installation when completed will be the most extensive electric hoisting plant for dock use in the world. The machinery will handle both cargo, freight and coal. The C. & C. people have taken another order for an 80-hp motor for shipment to the Rogers Locomotive Works, Paterson, N. J. A 40-kw and a smaller generator have been ordered by F. A. Kittredge, contractor of Everett, Mass., for installation in a Massachusetts manufacturing plant.

TO PURCHASE EQUIPMENT FOR MEXICAN MINES.—The Northern Mexico Development Company, which was recently organized under the laws of New Mexico, with a capital of $1,000,000, has acquired the Aventura & Santo Domingo mining properties, located in the Sabinal district on the Sierra Madre line, for the development of which considerable electrical equipment will be utilized. The company proposes to make a specialty of power plants for the operation of mines, etc. Britton Davis, of El Paso, Texas, is president of the concern, C. N. McAdoo, of Greensboro, N. C., vice-president and treasurer, and D. C. Sutton, of the Candelara Mining Company, at San Pedro, State of Chihuahua, Mexico, has been appointed general manager.

TELEPHONE GROWTH AT COLUMBUS, OHIO.—The directors of the Citizens' Telephone Company, which operates in connection with the United States Long-Distance Telephone Company, have decided to contract for the erection of an exchange building which will be 90 by 90 and three or four stories high. They have also decided to contract for an automatic switchboard that will accommodate 10,000 patrons and give the exchange a full capacity of 18,000 instruments. Their present capacity is only 6,000, but they have applications which have been on file for months to the number of 1,600. A director of the company says: "We paid 8 per cent. dividend last year and also built the Farmers' Telephone line, costing $100,000, out of the proceeds."

OFFICE BUILDING AND APARTMENT HOTEL.—Percival R. Moses, electrical engineer, 35 Nassau Street, New York, will act as consulting expert on the installation of electrical equipment for a ten-story office building, which is to be constructed at Binghamton, N. Y., by the Security Mutual Life Insurance Company. The capacity of the equipment has not yet been determined on. Mr. Moses is about to let lighting contracts for three 65-kw generators to be direct-connected to 13-in. x 12-in. high-speed simple automatic engines for the big apartment hotel now being built at Sixty-ninth Street and Broadway, New York, by the Construction Realty Company.

LIGHTING EQUIPMENT FOR SYDNEY.—Some $1,250,000 are to be expended in an extension of the lighting system in Sydney, New South Wales. Six hundred arc lamps will be used for public lighting, of which 340 will be erected at first. Tenders will very shortly be invited locally. The scheme has no reference to the Sydney City & Suburban Electric Traction system, which is being constructed for the most part with American equipment. The tramways are operated by the New South Wales Railways Commissioners, whereas the lighting system will be carried out by the municipal authorities of Sydney.

SHOSHONE FALLS POWER.—Articles of incorporation have been taken out in Idaho to the Shoshone Falls Power & Lighting Company, which will launch a large power enterprise. A power plant is being built on the Snake River from which current will be transmitted to Salt Lake and intermediate cities. Three power plants in all will be erected with a total capacity of 80,000 to 100,000 hp. The capital stock of the company is $2,500,000, with a bond issue of equal amount. All the stock and half the bonds are subscribed. Prominent men of Idaho and Utah are promoting the company.

ANOTHER MEXICAN PROJECT.—A company to be called the Rosa Amarillo Company is now in process of formation for the purpose of acquiring large properties in Mexico. An extensive electric power plant will be built to operate an electric railway, smelters, etc. M. D. Watson, who is primarily interested in the scheme, is now on his way here with a view to closing the financial end of the deal and awarding contracts for equipment. The property is situated at Cantitlan Purificacion, State of Jalisco.

EXTENSIVE MEXICAN ELECTRIC RAILWAY SCHEME.—The construction of an electric railway between Puebla, one of the leading cities in Mexico, and Vera Cruz, the principal seaport city of the southern republic, is mooted. The proposed line will pass the famous Popocatepetl sulphur volcano, which was recently purchased by a New York syndicate. General Muncio P. Martinez, of Puebla, is primarily interested in the railway scheme. The length of the road will be some 130 miles.

WATER POWER FOR LARGE MEXICAN COTTON MILLS.—Mexican advices state that an American syndicate has purchased the immense water fall known as Calda de Tontepec, located in the district of Acaxtian, in the State of Oaxaca. The syndicate proposes to utilize the motive power to be generated by the falls for the purpose of operating a large cotton factory situated in the vicinity, which is at present run by steam power. The price paid for the water rights exceeds $100,000, United States currency.

PENDING SPANISH CONTRACT.—The Westinghouse interests are figuring on a very important contract for the construction and equipment of a large central power station at San Andres de Polomar, Spain, in which it is proposed to utilize industrial gas for the generating of electric current for transmission principally to Barcelona for light and general power purposes. The length of the transmission line will be about 10 miles.

ELECTRIC TRACTION FOR SANTOS, BRAZIL.—Santos, one of the most flourishing seaport towns in Brazil, having a population of about 10,000 people, is to have an up-to-date American equipped electric traction system. James Mitchell, general manager of the Sao Paulo Tramway, Light & Power Company, Limited, is primarily interested in the project.

PENNSYLVANIA'S POWER HOUSE.—Milliken Brothers have been awarded the contract for the construction of the power house for the eastern section of the Pennsylvania, New York & Long Island Railroad. This is part of the Pennsylvania Railroad tunnel system. About 2,500 tons of structural steel will be used in the construction of the power house.

EQUIPMENT FOR JAPANESE ARSENALS.—The Westinghouse interests have recently been allotted several orders for electrical equipment to be installed in Japanese Government arsenals, etc. The orders were secured through the Japanese house of Takata & Co.

WARSAW EXPOSITION POSTPONED.—The electrical exposition which it was proposed to open at Warsaw, Poland, this year has been indefinitely postponed owing to the Russo-Japanese war.

General News.

THE TELEPHONE.

RIVERSIDE, CAL.—The Sunset Telephone Company will spend $15,000 in the extension and improvement of its service.

LOS ANGELES, CAL.—The Home Telephone Company, of Whittier, is installing a switchboard with a capacity of about 800 telephones.

LOS ANGELES, CAL.—The Home Telephone Company, of this city, has just issued an official statement showing that it has now installed and in operation 11,747 telephones, as compared with 8415 when the plant was taken over from the construction company last October. The authorized capital stock of the company is $3,000,000, with an authorized bonded indebtedness of $2,500,000. The company also announces that it has secured, for itself and affiliated companies in Southern California, the exclusive right to the use of the automatic telephone, and has entered into a contract with the Automatic Electric Company to install in the near future a new station on Grand avenue, in the southwestern section of the city, with 4000 automatic telephones. It will be followed immediately by similar sub-stations at East Los Angeles, Boyle Heights, and eventually the entire plant will be operated under the automatic system.

ALTON, ILL.—The Kinloch Telephone Company has installed a complete fire alarm system in the Alton hose houses in connection with its telephone system.

INDIANAPOLIS, IND.—The recent high water greatly damaged telephone property and impaired the service in this city. The water flooded the conduits.

OAKLAND CITY, IND.—The city council has granted the Oakland City Independent Telephone Company a franchise for a period of twenty-five years.

WARRICK, IND.—The Elberfield & Millersburg Telephone Company has been incorporated with a capital stock of $450. The incorporators are Fred Kampe, Henry Kelle and Henry Ahrens.

DALEVILLE, IND.—The Daleville Telephone Company has filed articles of incorporation with the Secretary of State. The capital stock is $10,000. C. H. Forrest, R. C. Stone and F. D. Rushing are the incorporators.

CAMDEN, IND.—The Camden Coöperative Telephone Company has filed articles of incorporation with the Secretary of State. The capital stock is $4000. U. E. Tesh, C. E. Baker, Fred G. Arnick, J. S. Plank and O. W. Wyatt are the incorporators.

SUMMITVILLE, IND.—The Independent Telephone Exchange at this place has been sold to the Madison and Delaware Counties Telephone Company. The purchasing company will at once improve the local plant, install a modern switchboard and extend and connect the lines with its own system.

LEBANON, IND.—The Central Union Telephone Company has taken steps toward the building of a local system in this city as a competitor of the Lebanon Telephone Company, an independent concern.. The Central Union claims to have a franchise granted by the council years ago that permits it to operate a local system.

LOGANSPORT, IND.—The Home Telephone Company in this city now has 1800 telephones in operation, and a hundred or more applications are on file waiting for telephones. The company has numerous connections with smaller systems and exchanges in the towns of the surrounding country. It has decided to purchase another switchboard, and has contracted with Butterfield & Co. to lay a number of additional cables. The company will establish a local exchange in Young America. Applications for local services in Walton and Galveston have also been filed with the home office.

RICHMOND, IND.—Representatives of the Greenville and Eaton, Ohio, and the Richmond Home Telephone Companies held a meeting in this city March 25 for the purpose of perfecting arrangements for long distance service The object is to get independent service between Dayton and Richmond this spring in order to make the circuit complete between St. Louis and the East in time for the World's Fair business. The distance between Richmond and Dayton is the only link that remains uncompleted to afford long distance service from St. Louis to Pittsburg and New York. It is understood that the United States Telephone Company will put in the Dayton-Richmond line as it operates the line between Dayton and Pittsburg. Connection will be made at Richmond with the new-long distance lines extending West. When these lines are completed the Richmond Home Telephone Company can get long distance service to all points of importance in the country.

WATERLOO, IOWA.—The United States Telephone & Telegraph Company will build an office building here.

WEBSTER CITY, IOWA.—The Martin Telephone Company will lay 10,000 feet of underground cable during the coming summer.

COOPER, MICH.—The Mutual Telephone Company has just been formed here.

JACKSON, MICH.—The Leslie Telephone Exchange with the United States Telephone Company, will build a trunk line to Eaton Rapids.

LAKE CRYSTAL, MINN.—The Blue Earth County Telephone Company has been incorporated with a capital stock of $25,000. The directors are William Crane, David Crane, and others.

MANKATO, MINN.—At the annual meeting of the Mankato Citizens' Telephone Company the following-named officers were elected: Dr. J. H. James, president; H. A. Patterson, vice-president; W. A. Willard, secretary and treasurer. Reports read at the meeting showed that the company is making steady progress and now has 806 telephones in use.

MEMPHIS, MO.—The Scotland County Telephone Company has been incorporated with a capital stock of $10,000. The directors are H. G. Merritt. C. M. Moore and others.

CAPE GIRARDEAU, MO.—The Cape Girardeau Bell Telephone Company, owned by Henry L. Rosier and John Tiapek, of Ste. Genevieve, has bought the Cape Girardeau Telephone Exchange. The new company expects to begin work at once in changing its system from a grounded to metallic circuit and otherwise improve the same.

ST. LOUIS, MO.—The directors of the Kinloch Long-Distance Telephone Company who went to Indianapolis, Ind., and Louisville, Ky., have returned to the city. They made arrangements for the extension of the present long distance service in several directions. At Louisville, representatives from independent companies in a territory extending through Kansas, Kentucky, Michigan, Ohio and Pennsylvania were met. As a result, arrangements were made to connect a large number of smaller lines in various states under a common management. The St. Louis subscribers to the Kinloch long distance telephones will soon be able to reach Cleveland, Columbus, Cincinnati and other Ohio towns. By June the arrangement will extend to Pittsburg, Harrisburg and Baltimore.

VERDIGRE, NEB.—The Verdigre Telephone Company has been incorporated with a capital stock of $10,000.

GUIDE ROCK, NEB.—The Guide Rock Telephone Company has filed articles of incorporation with a capital of $1000.

ABSECON, N. J.—The Keystone Telephone Company of Philadelphia is building a line between Camden and Atlantic City.

BINGHAMTON, N. Y.—The Hawleyton Telephone Company has been incorporated with a capital stock of $500. The directors are G. W. Vossberg, C. S. Gage and others.

WATKINS, N. Y.—The Reading & Rock Stream Telephone Company has been incorporated with a capital stock of $10,000. The directors are H. H. Smith and H. S. Howard.

ALBION, N. Y.—The Hotel Telephone Company of Albion has been incorporated with a capital stock of $50,000. The directors are C. M. Beattie, Garrison Babcock, Rochester, and G. L. Merrill, Albion.

MONTPELIER, OHIO.—The Montpelier Telephone Company has increased its capital stock from $15,000 to $50,000. W. A. London is president.

HARTSGROVE, OHIO.—The Hartsgrove Citizens Farmers' Association, which was formed late last year, now has 500 subscribers connected up and 35 miles of toll lines. The system is rapidly being extended. Robert Marro is president and E. W. Hunt manager.

ASHLAND, OHIO.—The Central Union Telephone Company will proceed at once with the work of installing an exchange in Ashland. The Central Union Company has been negotiating for the purchase of the Ashland exchange of the Star Telephone Company, an independent company.

GEORGETOWN, OHIO.—The Brown County Telephone Company, capital $20,000, has been incorporated by J. C. Martin, O. E. Bare, W. J. Marshall, H. C. London and G. Bamback. The company will build an exchange at Georgetown with lines through Adams, Highland and Brown counties.

GREENSBURG, PA.—The Borough Council has granted a franchise to the Johnstown and Pittsburg Long Distance Telephone Company.

PHILADELPHIA, PA.—According to dispatches from Philadelphia the Keystone Telephone Company since the first of the year has installed new telephones to the number of 1200. The statement is made by an official that the net earnings for the first quarter of the present year will surpass largely those of the corresponding period last year, when the profits were $41,000.

HILLSBORO, TEXAS.—The city council has voted to grant a franchise to the Independent Telephone Company.

CUSHING, TEXAS.—Dr. Crawford, of Alto, who has established a telephone exchange here, will make improvements.

DALLAS, TEXAS.—The application of Messrs. Waterbury and Whitney, of Houston, Texas, for a franchise for an independent telephone sysytem for the city of Dallas has been referred to a committee of the city council. There is considerable opposition to the franchise being granted.

BROADFORD, VA.—The Broadford Telephone Company has been incorporated with a captial stock of $5000. L. H. DeForest is president.

PRAIRIE DE CHIEN, WIS.—The Union Telephone Exchange of this city has been sold to J. W. Calloway.

CUMBERLAND, WIS.—The Dunn County Telephone Company will build lines through Dunn and Barron counties. Exchanges are to be put in at Barron, Ridgeland, Cameron, Dallas, Chetek and Rice Lake.

MERIDA, MEX.—Extensive improvements are to be made to the local telephone system here which was recently badly damaged by fire.

SIERRA DE ALMOLYA, MEX.—E. V. Combe is building a telephone line from this place to Vaca station, situated on the Mexican Central Railroad.

ST. JOHN, N. B.—Application is being made by a company seeking the right to conduct a general telephone business in the counties of St. John and Charlotte, N. B. The title of the new company is The Citizens' Telephone Company, and it will be connected with the present Forest Telephone Company at Calais, Me., with a main central office at Calais for both the New Brunswick counties.

OTTAWA, ONT.—The North American Telegraph Company is applying to the parliament of Canada for an amendment to the charter of the company to enable it to increase its capital from $1,000,000 to $10,000,000, and to extend its line to Manitoba and the Northwest and to change its head office from Kingston, Ont., to Winnipeg, Man.

TORONTO, ONT.—The Bell Telephone Company of Canada has offered the Board of Control of the city of Toronto to pay the city $20,000 per year for an exclusive franchise of five years, the price of telephones to remain at $50 and $30 as at present. The Stark Telephone Company offered to furnish telephones at $6 per year, with a charge of one cent per call up to $15. The Canadian Telephone & Telegraph Company offered to furnish telephones at $36 and $24. The Board has taken time to consider these bids.

Electric Light and Power.

SAN FRANCISCO, CAL.—The California Gas & Electric Corporation made its first annual payment, under its sinking fund provisions, to the Mercantile Trust Company on March 15. The money is to be invested in the underlying securities and the bonds of the corporation.

SAN FRANCISCO, CAL.—The Reno Power, Light and Water Company has been incorporated with a capital stock of $1,000,000 by P. L. Flannigan and W. H. Patterson, both of Reno, Nev.; Charles L. Gibb, of Berkeley, and Joseph A. Fontaine and Frank P. Deering, of San Francisco.

LOS ANGELES, CAL.—The Tracy Engineering Company, of San Francisco, wants to install a 500-hp plant for the city of Riverside and sell it to the city at the end of ten years, the city to buy the power in the meantime at the rate of $5.90 per horse power per month and pay for a minimum load of 300-hp.

LOS ANGELES, CAL.—The Alamo Electric Power and Milling Company proposes to install a 500-hp plant at Ensenada, Lower California, to serve the principal mines of the famous Alamo mining district, at an expense for power and milling machinery of not less than $150,000. The company's headquarters are in Los Angeles. W. E. Hampton, an electrical construction engineer of San Francisco, is drafting the plans for the power plant.

SAN FRANCISCO, CAL.—The San Francisco Gas & Electric Co. has, in a general way, planned to make a considerable increase in its electric generating equipment. It is considering the advisability of adding 10,000-kw in generating capacity at the independent plant known as Station "A." This would permit of shutting down the steam plants at the other two power stations. Contracts have been placed with the Westinghouse Electric & Manufacturing Co. for 1300 series alternating arc lamps with the necessary 200-light regulators for the same. The new lamps will enable the company to do away with the direct current series arcs in street lighting as it has already done in commercial lighting.

WASHINGTON, D. C.—The Atlas Light & Power Company has been incorporated here by A. C. Smith, S. J. Lamson, E. W. Scribner, E. L. Bradford, P. H. Burch, R. Wermelle and R. K. Van Mater.

WASHINGTON, D. C.—Bids will be received April 12 at the Bureau Supplies and Accounts, Navy Department, Washington, for furnishing at the navy yards, Norfolk, Va., and Pensacola, Fla., a quantity of arc lamps, electrical supplies, conduit and fittings, etc. H. T. B. Harris, Paymaster-General, U. S. Navy.

TERRE HAUTE, IND.—The Terre Haute Electric Company will build a new power house in this city. Contracts for the building have not yet been let.

CICERO, IND.—The town council has granted a 25-years' franchise to John Plain for an electric lighting plant. Mr. Plain announces that he will at once erect a new electric lighting system here.

MENTONE, IND.—The Mentone Electric Light and Power Company's plant has been sold through the J. S. Maurer & Company agency, of 804 Monadnock Block, Chicago, to J. H. O'Rourke, of Algonac, Mich.

ANNAPOLIS, MD.—A bill was offered in the House by Mr. Lipman to provide for municipal ownership of electric lighting plants in Baltimore City. A motion to lay the order on the table was carried.

MERRIMAC, MASS.—Jas. Dickens, of Newburyport, is preparing plans for the electric light plant for Merrimac.

ST. LOUIS, MO.—The Ada Electric Light and Power Company has been incorporated with a capital stock of $40,000, full paid. The incorporators are Charles I. Patterson, Allen B. Patterson and William F. Klanke.

VERSAILLES, MO.—W. K. Palmer, Kansas City, Mo., is engineer for the municipal lighting plant for Versailles. Plans and specifications are ready. Bids will be required on boilers, engines, generators, switchboard, poles, etc., together with the building.

ST. LOUIS, MO.—The city of St. Louis, through the Harbor and Wharf Commissioner, March 23, formally ratified its previous verbal acquiescence in the contention of the Laclede Power Company, that the latter had riparian rights in front of its station at the corner of Lewis and O'Fallon streets. This gives the company the right to take water from the river which it will use for condensing purposes in the operation of its engines, and ends the controversy which has been going on for two years and which came acute when it was discovered last winter that the power company was building an intake beneath the wharf opposite its works.

ST. LOUIS, MO.—A plan to brilliantly illuminate the new city hall is being worked out by Thomas B. Carter, supervisor of city lighting. The Twelfth street entrance is to be lighted from fourteen posts of artistic design. Six of these will support clusters of 25 incandescent lights. Four smaller posts, with 12 lamps each, will light the circular driveway, and four of the same size will illuminate the portico. Arc lights on specially designed brackets will be placed at the Clark avenue and Market street entrances. The rotunda, now being completed, will be lighted by 2000 incandescent lamps. Of these 250 will form a chandelier below the skylight, and the others will be fixed to the pillars surrounding the rotunda. The fixtures for these are being designed by the architects. Many other lights will be placed in the halls. The total number will be about 5000.

HELENA, MONT.—The Ox Bow, in the Missouri River, near Helena, is to be a thing of the past according to the plans of the Ox Bow Power Company, recently organized. The Ox Bow is a loop in the river about 12 miles around but at one point only a quarter of a mile separates the two turns of the river. There is here a difference in level of about 20 feet, and it is proposed to construct a dam, make a canal, and establishing a power plant at some convenient point. It is estimated that the expense of putting in such a plant will be about $750,000. Before work can be commenced, a congressional enactment, permitting the damming of the river, will be necessary.

WATKINS, N. Y.—The citizens have voted to issue $20,000 bonds to construct an electric light plant, to be operated in connection with the water works.

CANTON, N. Y.—The Canton Electric Light & Power Company has petitioned for a 20-year franchise for lighting the village. It is proposed to install new machinery.

BURGAW, N. C.—John W. Reilly, of Wilmington, is interested in the construction of electric light plants at Burgaw and Clinton.

WAYNESVILLE, N. C.—B. J. Sloan has contracted to furnish this city with power for lighting for 10 years, the power to be generated at the falls of Pigeon River, by the construction of a dam. The capacity of the plant will be 1500-hp.

HAMILTON, OHIO.—The city will issue $5000 bonds for improving the lighting system.

PHILO, OHIO.—C. U. Shryock, of Zanesville, has secured a franchise from this village for the construction of water works and an electric light plant. The villages of Duncan's Falls and Taylorville will also be supplied.

BELLEVUE, OHIO.—The franchise of the Bellevue Light and Power Company expires May, 1905. The council is considering a proposition to erect a municipal lighting plant. A committee has been appointed to investigate the cost of such a plant.

OKLAHOMA CITY, OKLA. TER.—F. C. French, of Oklahoma, has made application for an electric light franchise.

OREGON CITY, ORE.—Supplementary articles of incorporation have been filed by the Oregon Water Power & Railway Company, changing its name from Oregon General Electric Company, under which it was originally formed. Fred. S. Morris, J. Frank Watson, A. B. Croasman, W. H. Hurlburt and William T. Muir are the incorporators.

TERREHILL, PA.—Michael N. Nolt, New Holland, Pa., writes that he proposes constructing an electric light plant on Conestoga River, at a cost of $6000.

CHARLESTON, S. C.—By a new contract with the Consolidated Company, of Charleston, this city will save over $5700 on lights. Arc lights are reduced from $97.50 to $80 per year, to be followed the next year by a reduction to $75.

DAYTON, TENN.—Edgar Stone, of the Dayton Light and Power Company, writes that it is proposed to construct an electric light plant, at a cost of $8000.

KNOXVILLE, TENN.—The city council of Knoxville has named a committee on municipal ownership of the electric light plant. Mayor Gass is reported as being in favor of the new plan.

RUSK, TEXAS.—W. W. Welsh is interested in the construction of an electric plant.

UVALDE, TEXAS.—Colonel Ike Pryor and son, Dave, contemplate installing an electric light and power plant at Uvalde. They are also arranging to establish a large irrigation plant near here.

PRAIRIE VIEW, TEXAS.—An electric light and power plant is to be installed at the State Prairie View normal school, situated here. Prof. Brown, of College Station, Texas, can give information.

RICHFIELD, UTAH.—The Clark Power Company is considering the construction of a power plant near here to supply power for all towns of the county. The plan also includes the construction of electric railways.

WEST SEATTLE, WASH.—The Council has passed an ordinance requiring that all electric light and power wires be placed in underground conduits.

FOND DU LAC, WIS.—The bid of the Citizens' Light, Heat and Power Company, of Milwaukee, for the franchise, under which a new electric lighting and power plant is to be established in this city, was accepted by the Common Council.

SUNDANCE, WYO.—It is reported that the Economic Power Company, organized by Henry K. Mayham, of Denver, Colo., will build a $900,000 power plant west of this place, to supply power and electric light to many towns and mines in the Black Hills.

KINGSTON, ONT.—It was voted to purchase the plant of the Light, Heat and Power Company.

OTTAWA, ONT.—The rights of Mr. E. S. Jenison, of Chicago, to the water power of the Kekabeka Falls and Ecarte Rapids, Ont., have been fully restored by the private bills committee of the Ontario Legislature.

BRANTFORD, ONT.—A peculiar accident happened recently to the electric plant of this city. It appears that muskrats burrowed through the embankment skirting Lake Mohawk, whence the electric plant obtains its power, causing the earth to cave in and effecting a large breach and put the plant out of business. An auxiliary plant was set up, but local factories, run by electricity, were forced to close pending repairs to the embankment. The pranks of the muskrats cost the electric company upwards of $5000.

OTTAWA, ONT.—The Dominion government has determined not only to light the Welland Canal by electricity, but by the same power to operate the gates, valves, bridges and sluiceways of the canal. The electric energy will be furnished by the Cataract Power Company, of Hamilton, Ont. The whole stretch of the canal will be lighted instead of merely the locks as at present. Some 550 arc lights will be distributed between Port Dalhousie and Port Colborne, a distance of 27 miles. At each of the 25 locks there will be six arc lights, while along the banks of the canal there will be one light in every 400 feet. In addition there will be a special equipment of arc lights for the piers at the head and foot of the canal.

MONTREAL, QUE.—The Shawinigan Water and Power Company, of Shawinigan Falls, Que., has just completed arrangements for the erection of another transmission line, from the Falls into Montreal, with a capacity of 10,000 additional horsepower. This entire additional power will be taken by the Montreal Light, Heat and Power Company. In order to meet the increasing demands for power, the Shawinigan company is just completing at its works the installation of a third unit consisting of a water wheel with a capacity of 6000 hp and a generator of 3750 kw capacity, thus giving the company an increased output of 5000 hp. A similar additional unit will be installed this summer.

THE ELECTRIC RAILWAY.

BIRMINGHAM, ALA.—The Bessemer, Brookwood & Blocton Railway & Light Company has been granted a franchise by the city of Birmingham to build an electric railway.

CAMDEN, ARK.—The Interurban Transit Company has been incorporated by H. C. Homeyer, C. P. Brice, C. C. Gunnels and J. G. McDonald. The company proposes to carry passengers and freight and to sell electric power. Capital, $350,000.

WASHINGTON, D. C.—The Old Dominion and Great Falls Railway Company has bought a $23,000 site in Washington for its power plant.

WILMINGTON, DEL.—Rights of way are being secured for the extension of the Middletown & Odessa Electric Railway from Middletown to Clayton and Smyrna.

ATLANTA, GA.—It is stated that the recently incorporated Georgia Traction Company has been successfully financed and that it will be built between Athens and Carnesville, Ga. Mr. Van Wey, of Toledo, Ohio, is president of the company.

FREEPORT, ILL.—Right of way is being secured for the proposed electric railway from Freeport to Polo and Dixon, and application has been made for a franchise in Polo. O. T. Smith is president of the company.

EAST ST. LOUIS, ILL.—Articles of incorporation have been filed by the St. Louis, Vandalia & Eastern Electric Railway, with a capital stock of $50,000. The incorporators are: William M. Folger, Charles G. Sonnerman, George D. Steinbauer, H. C. Doyle, T. N. Lakin, of Vandalia.

CHICAGO, ILL.—The Chicago City Railway Company, Chicago, contemplates the erection of a great central electric power plant at West Thirty-eighth and Halsted streets, to cost $4,000,000, the purpose being to operate all the trolley lines from the one central power plant.

TAYLORVILLE, ILL.—The stockholders of the American Central Traction Company have perfected their organization by electing the following officers: J. N. C. Shumway, president; Ernest Hoover, vice-president; Warren Powell, second vice-president; David M. Sharp, secretary and manager; E. W. Height, treasurer. The company has been incorporated at $250,000, and will begin the construction of interurban lines from here to Assumption, Mount Auburn, Springfield and East St. Louis.

CRAWFORDSVILLE, IND.—It is announced that the Consolidated Traction Company will soon receive bids for the construction of a large power house in this city. Edward Hawkins is president of the company.

WATERLOO, IOWA.—The Rapid Transit Company proposes to extend its line to Ossian.

MARSHALLTOWN, IOWA.—Petitions are being circulated in this city by the Marshalltown Electric Street & Interurban Railway Company, to be presented to the City Council, to call a special election to decide whether or not a 3-per-cent. tax shall be levied for the purpose of aiding the construction of an interurban line from Marshalltown to Grundy Center. The company asks the payment of one-half of the tax when the line is completed from Marshalltown to Grundy Center and the other half one year later. J. G. White & Company, of New York, are understood to be considering a proposition to build the line.

GREENVILLE, LA.—The City Council has granted the concessions asked by the Delta Light and Power Company for the extension of its tracks. It was decided at a meeting that if this city and Leland would donate or subscribe $50,000 of stock the company would extend the line to Leland, which is about 12 miles from Greenville.

ANNAPOLIS, MD.—A "Jim-Crow" bill for the electric cars of the whole State has been introduced in the House.

BAY CITY, MICH.—The Bay City Traction & Electric Company will install a storage battery plant in the building on Water street now used as office quarters.

FARIBAULT, MINN.—Hon. Donald Grant, of this place, has under consideration the building of an electric railway here.

MINNEAPOLIS, MINN.—The Minnesota Power & Trolley Company has been advised from Washington that the President has signed the bill permitting the construction of a dam across the Mississippi River, 2 miles above Elk River and without requiring the installation of a lock.

DULUTH, MINN.—Articles of incorporation of the Lake Superior & Northern Railway Company have been filed. The incorporators are: L. R. Martin, who is president and treasurer; H. P. Gardiner, vice-president and secretary; H. B. Fryberger, H. C. Fulton and M. A. Armstrong. The company is capitalized at $50,000, while its limit of indebtedness is $5,000,000. The purpose of the corporation is to construct and operate railway lines in this state and elsewhere, build telephone and telegraph lines, carry on a freight and passenger business and acquire right of way, depot grounds and freight yards.

JEFFERSON CITY, MO.—The Forest Park & Richmond Heights Railway Company has been chartered to build a branch line one mile long from St. Louis City to Richmond Heights, and has a capital of $25,000. The stockholders are: N. E. Niesen, Robert Rutledge, James McCausland, Charles J. Roberts and Bernard Christian.

ST. JOSEPH, MO.—The St. Joseph Interurban Railway Company filed articles of incorporation March 22. Its capital stock is $100,000. The incorporators are: George C. Sims, of Des Moines, Iowa; A. C. Plummer, of Altoona, Iowa; Alice M. Butler, John C. Landis, Jr., of St. Joseph. The company will build an electric railway from Savannah to Platte City, through St. Joseph.

ALBANY, N. Y.—The Assembly Railways Commission has decided to report favorably the Wallace third-rail protection bill. It requires companies operating third-rail lines to cover or in some way guard the third rail, so that persons will not run risk of injury from it. The elevated roads in New York City are, of course, the main ones affected by the bill.

ELMIRA, N. Y.—A certificate of incorporation has been filed in the office of the Secretary of State for the Elmira & Corning Short Line. Among the directors named are: Joseph Powers, of Troy; G. Tracy Rogers, of Binghamton; William R. Compton, of Elmira; A. Lee Smith, of Elmira. It is understood that the Powers & Mansfield Company has made the surveys and is actively connected with the enterprise. The length of the line to be built is about 13½ miles from the city limits of Elmira into the city of Corning, and that of this distance 12½ miles is upon private right of way. It is proposed to equip the line with a protected third rail.

CLEVELAND, OHIO.—The Lake Shore Electric Railway Company, Cleveland, Ohio, has placed a contract with the Aermotor Company, Chicago, for two structural steel towers to be used in carrying high tension circuits over Black River, Lorain, Ohio.

TOLEDO, OHIO.—Stockholders of the Toledo & Indiana Railway Company and the Toledo, Hicksville & Fort Wayne Railway Company, which is affiliated with the first mentioned, will meet April 5 to consider a proposition to extend the Toledo & Indiana Railway to Fort Wayne by way of Defiance.

CORTLAND, OHIO.—C. G. Phillips, general manager of the Warren, Cortland & Jefferson Traction Company, states that preliminary surveys for the road have been completed, and that the work of grading will be started at once. Engineers of the Westinghouse Electric & Manufacturing Company have suggested that a large power house be erected at Kinsman to supply power for this line as well as the Cleveland & Sharon Traction Company, which is being built by the same interests.

GUTHRIE, OKLA.—A charter has been issued to the Oklahoma City, Lexington & Sulphur Springs Electric Railway Company, of Lexington. The capital stock is $1,000,000. The stockholders are: Charles Stewart, of Parkersburg, W. Va.; J. S. Little, H. L. Forehand, E. Duffy, W. J. Reed, E. J. Keller, R. E. Thacker, G. A. Teague, A. Hutchins, E. P. Mosely, Jay Sherman, of Lexington.

SCRANTON, PA.—The directors of the Scranton Railway Company have authorized an outlay of $300,000 for improvements to the system.

FRANKLIN, PA.—A company, with $400,000 capital, has been formed in Pittsburg to build a 53-mile electric railway between Franklin and Butler, where connection will be made with a line between Pittsburg and Butler, now approaching completion.

YORK, PA.—It is stated that the capital stock of the York County Traction Company is to be increased from $1500 to about $5,000,000, preparatory to the building of new lines in this county. Lines are planned to run to Hanover, Dillsbury, Lewisberry, Yorkana, Airville, Brogneville, Collinsville and Delta.

PHILADELPHIA, PA.—Plans have been approved by the Board of Surveyors for double tracks for the Philadelphia Rapid Transit Company on Twenty-ninth street, from Lehigh avenue to Allegheny avenue. The line will be a connecting branch of the Lehigh and Allegheny avenue lines.

MECHANICSBURG, PA.—The Cumberland Valley Electric Passenger Railway Company will be offered for sale on June 25, under foreclosure brought by the Harrisburg Trust Company, trustee. The successful bidder will have to pay $25,000 cash on the spot when the sale is declared, and the balance of the purchase money must be forthcoming on July 1.

LEWISTOWN, PA.—The Lewistown & Reedsville Electric Railway Company contemplates important improvements. Contracts have been awarded to P. E. Lane & Co., of Atlantic City, N. J., for the extension of the line from the present terminus to the Pennsylvania Railroad station at Lewistown Junction.

HARRISBURG, PA.—A charter has been granted at the State Department to the Inter-State Electric Railway Company, capital $200,000, to build a 20-mile line from the intersection of Vine and Main Streets, Port Allegheny, McKean County, through the towns of Burtonville, Roulette, Mina and Coudersport, Potter County. The directors are: L. B. Seibert, of Coudersport, president; H. H. Cobb, F. L. Andrews, M. L. App, D. S. Seibert, W. T. Church, H. A. Avery.

LEAD, S. D.—An electric railrway, fifty miles long, will be built this spring connecting Lead with the coal mines of northeastern Wyoming.

BELTON, TEX.—Arthur C. Kretz, of Reading, Pa., engineer for the proposed Temple-Belton Interurban Electric Railway, is here making a preliminary investigation of the route of the proposed road.

WACO, TEX.—A movement has been inaugurated looking to the construction and operation of an interurban electric railway between this city and Dallas, by way of Hillsboro and Waxahachie. Colonel James B. Baker, of Waco, is interested in the project and can give information.

BELLINGHAM, WASH.—Specifications have been ordered by the City Council for a municipal electric lighting plant to be operated by the power of Whatcom Falls.

COLFAX, WASH.—The County Commissioners have granted the franchise for an electric railway asked for by S. J. Crutcher, A. J. Smith and associates of Pine City, through the north part of Whitman County to Colfax. The promoters purpose building a line from Spokane via Spangle, in Spokane County, to Pine City, in Whitman County, thence via St. John to Colfax.

ST. ANSELME, QUE.—The Ste. Claire Electric Company is considering the construction of an electric railway through the counties of Dorchester, Bellechasse and Levis.

TORONTO, ONT.—Notice is given that application will be made to the Parliament of Canada, at its next session, for an act incorporating a company under the name of the Nipissing, Ottawa & Montreal Railway Company, with power to construct a line of railway from a point at the east end of Lake Nipissing to the city of Montreal, and also a line extending from said point along the north side of Lake Nipissing and French River to a point on Georgian Bay, and to acquire, own and operate water power and generate electric power for lighting and motive purposes.

New Industrial Companies.

THE INSULATED COPPER COMPANY, of Islip, N. Y., has been incorporated with a capital of $25,000. Directors: W. K. Post, R. D. Upham and H. B. Johnson, New York.

THE BAXTER LIGHTING COMPANY has been incorporated at Camden, N. J., with a capital of $25,000. Incorporators: Lewis F. Baxter, George M. De Gunther and L. Howard Weatherby.

THE MARINE MAGNETIC CONTROL COMPANY, of New York, has been incorporated; capital, $100,000. Directors: J. O. Stevens, Plainfield, N. J.; Albert Graham and Edward Pfuhler, New York.

THE COLONIAL ENGINEERING COMPANY, of New York, has been incorporated; capital, $1000. Directors: T. J. Kane, New Brunswick, N. J.; J. A. C. Johnson, Englewood, N. J., and W. C. Furley, Brooklyn.

THE ELECTRIC AND STEAM ENGINEERING COMPANY has been incorporated at St. Louis, Mo. The capital stock is $5000, full paid. The incorporators are B. D. Kribben, W. J. Burton, E. R. Suits and R. H. Moore.

THE TOWER STORAGE BATTERY COMPANY, Cleveland, O., capital stock $10,0000, has been incorporated by E. B. Robbins, T. Rowland, C. A. Gilbert, G. D. Reed and J. H. Van Derveer. The company will manufacture automobile batteries.

THE FARIBAULT MANUFACTURING COMPANY has been organized at Faribault, Minn., for the manufacture of dynamos, motors and gasoline engines. Active operations have already commenced. Hon. Judge James Hunter is vice-president of the company.

Legal.

WIRELESS TELEGRAPH LITIGATION.—Judge Lacombe in the United States Circuit Court, New York City, on March 30, denied an application for a preliminary injunction against the De Forest Wireless Telegraph Company and others in proceedings instituted by the National Electric Signalling Company for alleged infringement of patent. The application sought to restrain the De Forest company from using certain apparatus to which the National Company claims exclusive rights, chiefly the liquid barretter patented by Prof. Reginald A. Fessenden, an instrument for receiving Hertzian waves. The De Forest company was represented by Cornelius D. Ehret, of Philadelphia, and Francis X. Butler, and the National Electric Signalling Company by Kenyon & Kenyon. Judge Lacombe, in his opinion, did not pass on the merits of the case, simply stating that the question at issue should be left for final hearing.

Obituary.

CHARLES J. POWER, a well-known telegrapher, died at his home in New York City, March 21. At the time of his death he was chief operator in the Commercial News Department of the Western Union Telegraph Company, at 195 Broadway. Deceased was 43 years of age.

Educational.

LEHIGH UNIVERSITY.—The Register of Lehigh University, South Bethlebem, Pa., just issued, copies of which may be had on application, shows the attendance of 615 students from 24 States and 10 foreign countries, of whom 90 are taking the course in electrical engineering. There are 54 in the teaching staff. Thirteen four-year courses of instruction are offered at the University: the classical course, the Latin-scientific course, the courses in civil, mechanical, marine, metallurgical, mining, electrical, and chemical engineering, analytical chemistry, geology, physics, and electrometallurgy. A list of graduates of the University, 1304 in number during the 38 years of its existence, indicates that this institution is exerting a very marked influence on the industrial development of the United States, and also of foreign countries. Provision is made for worthy and needy students whereby they may postpone payment of tuition until after graduation.

UNIVERSITY OF WISCONSIN, SUMMER SCHOOL FOR ARTISANS.—The fourth annual sessions of the Summer School for Artisans, held under the direction of the College of Engineering of the University of Wisconsin, begins June 27, and continues for a period of six weeks. Courses of study are offered in the following subjects: (1) Steam, Gas and Other Heat Engines. (2) Applied Electricity. (3) Mechanical Drawing and Machine Design. (4) Materials of Construction, Fuels and Lubricants. (5) Shop Work. Three sessions of this school have been held. The first, in 1901, marked a new departure in educational methods and was begun as an experiment, but its success has justified the continuation of these sessions. In 1903 students came from twelve states, and among them were representatives of the following occupations: Machinist, electrician, draftsman, stationary engineer, erecting engineer, chief engineer of electric plant, carpenter and manual training teacher. The class instruction consists of lectures given by members of the regular faculty of the College of Engineering, and as the entire laboratory equipment of this college is available for instruction in the school, opportunities are thus afforded for laboratory practice, otherwise available only in a regular engineering course. A large number of the students enrolled have had correspondence instruction. The requirements for admission do not extend beyond a working knowledge of English and arithmetic, but the policy is to allow a large amount of individual work so that the student may take advantage of all the preparation he has obtained. As the demand renders it necessary, advanced courses will be established in the various subjects.

Personal.

MR. PAUL JONES has been appointed secretary and treasurer of the Lincoln, Neb., Gas & Electric Light Company. He was formerly connected with the Denver Gas & Electric Company as its accountant.

MR. W. E. GILMORE, the active manager of the Edison Mfg. Co., and several other Edison enterprises at Orange, N. J., leaves this week on a trip to Europe to look after various important matters there in Mr. Edison's behalf.

MR. BENJAMIN H. BLOVER, formerly with the Underwriters' Laboratories and the past year engineer of the Chicago Fuse Wire & Mfg. Co., at Buffalo, N. Y., is now associated with the Westinghouse Electric & Mfg. Co., at East Pittsburg, Pa.

MR. THOMAS B. BAILEY'S election to the directorate of the American Telephone and Telegraph Company to fill the vacancy caused by the death of J. Malcomb Forbes is said to be but a temporary one. Mr. Bailey has his hands full as purchasing agent of the company.

MR. C. J. H. WOODBURY recently addressed the Worcester, Mass., Board of Trade on the "Telephone System of To-day." He fully described the modern telephone system and its operation, the subject being illustrated by over 100 lantern slides.

MR. M. J. FRANCISCO, of Rutland, Vt., past president of the National Electric Light Association, has been confined to his bed for seven weeks past with a severe attack of pneumonia. He is recovering, but it may be some weeks before he is able to resume active duties.

MR. P. G. GOSSLER has resigned his position as general superintendent and engineer of the Montreal Light, Heat and Power Company, to take effect May 1. He has accepted the general managership of the operating department of J. G. White & Co., of New York.

MR. A. C. RAHE, manager of the Smith Storage Battery Company, of Binghamton, N. Y., was in New York last week. Not only was he interested at the time in storage batteries for special lines of work, but he had in mind some other lines which promise important and interesting developments.

MR. W. B. POTTER, chief engineer of the electric railway department of the General Electric Company, has returned from a recent trip to the West Indies, whither he went to rest and recuperate after a severe attack of overwork and grip. He has benefited greatly by the holiday in summer seas.

MR. EDWIN W. RICE, JR., has been elected during the past week a director of the General Electric Company to fill the place left vacant by the death of William C. Whitney. Mr. Rice is a director in several street railway and electric lighting companies, and is already a vice-president of the General Electric Company.

MR. E. C. HURD, president of the proposed electric railway from Omaha to Beatrice, has completed plans and has come on to New York to finance the undertaking. Before leaving, he arranged with the Omaha & Council Bluffs Street R. R., which owns all Omaha electric lines, to permit the use of its tracks as soon as the new line is completed.

MR. C. H. HINES, electrical engineer of the mechanical department of the Canadian Pacific Railway, is at Fort William, Canada. The Canadian Pacific announces that it will build a large central power house at Fort William and equip it with two 750-hp engines, to be used to generate current to drive all the machinery in the big grain elevators, as well as coal-handling machinery.

DR. F. A. C. PERRINE.—The Clarkson School of Technology has just reprinted in pamphlet form, as part of its *Bulletin*, Dr. Perrine's admirable Founder's Day Address, "The Success of the Educated Man." He claimed that the modern "humanities" are really the great engineering arts, and that the work of the educated engineer has elevated the entire world up to more pleasant places for mankind to live in.

MR. C. C. STARR.—The Canadian Westinghouse Company, Ltd., of Hamilton, Canada, has recently engaged Mr. C. C. Starr, who was formerly connected with the firm of John Starr, Son & Company, to act as its representain the maritime provinces, with headquarters at 134 Granville street, Halifax, N. S. The maritime provinces are included in the district of the Canadian Westinghouse Company's Montreal office, and Mr. Starr will be consequently an attaché of that office.

MR. R. M. BARWISE, well known in the electric automobile and incandescent lamp fields, is returning to New York from Philadelphia and will carry on for the Pope Mfg. Co. on upper Broadway, a handsome garage and show room for Pope Waverly electrics. Mr. Barwise, in addition to considerable executive force, and electrical knowledge, combines a close familiarity with the bicycle and automobile arts, and a host of old friends welcome him under his new connections with Col. Pope and Mr. E. Mason.

MR. W. W. WHEATLEY.—We learn that Mr. W. W. Wheatley, who was for a time superintendent of the trolley system of the Brooklyn Rapid Transit Company, has gone to Mexico, where he is to assume charge of the electric railway system of the City of Mexico. Mr. Wheatley sailed last month to take up his new work. It is said that his salary is to be $15,000 a year in gold. The Mexican road is owned by Wernher, Beit & Company, of London. Mr. Wheatley was with the Brooklyn Rapid Transit Company for two years. He then became general manager of the Public Service Corporation in New Jersey, but remained less than a year under extremely exacting and trying conditions.

MR. EDWARD WESTON, of Newark, N. J., has had conferred upon him the degree of LL.D. by McGill University, of Montreal, Canada, in recognition of his inventions and investigations in electrical science. It is appropriate that this well-deserved acknowledgment should come from Canada, and from one of the most progressive seats of learning under the British flag, and one where moreover electricity has received special attention. Mr. Weston has been an American citizen a great many years, and all his notable work has been done in this country, but he is an Englishman by birth, and in many of his attributes. He studied medicine originally, and first took up electrochemistry. He was president of the American Institute of Electrical Engineering in 1888.

MR. W. F. BAKER has been appointed contract agent of the New York Telephone Company in succession to Mr. F. H. Bethell, promoted to the management of the Potomac Telephone Company, with headquarters in Washington. Mr. Baker has been 6½ years with the department, and for the last two years special agent for the Dey street division. He is a graduate of Harvard University, class of '93, and is a native of Springfield, Mass. He was at one time in the insurance business, and was also city editor of the *Springfield Union*, one of the leading newspapers of New England. Although the company has to-day no fewer than 140,000 subscribers in connection or under contract for service, Mr. Baker believes enthusiastically in the possibilities of great growth and extension in the metropolitan territory.

MR. HARMAN S. SALT has been made manager of the Dale Company, of New York City, and assumed his new duties on April 1 at headquarters in the Hudson Street factory. Mr. Salt, although quite a young man, has had a long and successful career in the field of electrical manufacturing. He entered the service of the Western Electric Company, in New York City, in 1887. He displayed executive ability from the start, and in 1891 was put at the head of the export department, in which during the past thirteen years he made a most creditable record. For a time he was also out on the Pacific Coast for the Company, with beneficial results to its affairs there. Mr. John Dale in his growing business in lighting fixtures and specialties has therefore enlisted experience and ability, in Mr. Salt, that will prove extremely valuable.

MR. J. W. LATTIG.—At its offices, 112 North Broad street, Philadelphia, the employees of the United Telephone & Telegraph Company, as well as the officers of the York State Telephone Company, the officers of the Eastern Electrical Construction Company and the officers of the Eastern Telephone Manufacturing Company, with whom he has held business relations, presented last week to the retiring general superintendent, Mr. J. W. Lattig, a handsome dinner set of 150 pieces, and a beautiful cut glass water set. Mr. Lattig has been with the United Telephone & Telegraph Company for two and one-half years and during that time, as shown by the handsome gift, he has earned the good-will and earnest co-operation of everybody from the officers of the company on down. Mr. Houck, the traffic manager, made the presentation in a neat speech, to which Mr. Lattig replied briefly and feelingly. Mr. Lattig's resignation as general superintendent of the company went into effect on April 1, when he assumed new duties with the Delaware & Atlantic Telephone & Telegraph Company.

HON. S. N. D. NORTH, director of the U. S. Census Bureau, contributes to the *Annals of the American Academy* an interesting article showing how, under the protective tariff, American manufacturers have grown so strong that they have now only invaded foreign markets but penetrated to foreign soil as a foothold. He cites a number of examples and says: "The Western Electric Company, of Chicago, is interested in extensive factories in London, Paris, Antwerp and Berlin, not all of them carried under the name of that company, but all of them established and controlled by its capital. The General Electric Company has three or four such establishments, and has recently constructed a huge new factory at Rugby, in England. The Westinghouse Company has just finished, at Trafford Park, in England, one of the largest electric factories in Europe, employing two or three thousand men, and it has other factories in Havre, France, and St. Petersburg, Russia. The Singer Machine Company has three large plants in Europe, under its direct control. The Chicago American Tool Company is building a plant at Frazerburg, near Aberdeen. The Hoe printing presses are made in London, as is also American linotype machinery. The Draper Company has recently completed its new factory in Lancashire, to supply the greatest cotton-manufacturing district of the world with the American fast-running Northrup loom. This list might be extended indefinitely, and a fine field for investigation is opened for the full measurement of this remarkable transplantation."

Trade Notes.

MR. A. C. LIPPINCOTT, 109 Franklin Avenue, Scranton, Pa., will be glad to send to any engineer a fine catalogue of indicators, reducing wheels, planimeters, steam separators, etc., by addressing him as above.

PITTSBURG TRANSFORMERS.—The Pittsburg Transformer Company has issued a little folder giving some suggestive facts about these well-known transformers. The folder is accompanied by an attractive calendar for April. The picture is that of a pretty girl, presumably one of those referred to in the folder.

AUTOMATIC TELEPHONE EXCHANGES.—In a pamphlet of 32 pages issued by the Automatic Electric Company of Chicago are given copies of many letters received from patrons of the Home Telephone Company of Dayton, Ohio, testifying to the satisfactory service rendered by the automatic exchange in that city. An illustration of the Dayton automatic exchange is given, which shows a very extensive equipment.

THE NATIONAL-ACME MANUFACTURING COMPANY, Cleveland, Ohio, maker of the Acme multiple spindle automatic screw machine, does a large trade in special work for manufacturers of electrical apparatus. These specialties include set screws, cap screws, machine screws and milled work turned from steel, iron, zinc and brass. The company has recently issued an attractive monthly calendar, which gives a view of one of its machines.

"BURIAL EXPENSES" is the title of a folder issued by the Ewing-Merkle Electric Company, 1006 Pine Street, St. Louis, Mo., on the subject of the Stombaugh guy anchor. The title is rather funereal, but the subject is a living one to telephone men, who are eternally confronted with the problem of guying poles. The Stombaugh anchor meets such cases very completely. It screws into the ground and affords an anchorage that is steadfast and good for all time.

STEAM HAMMERS.—The David Bell Engineering Works, Buffalo, N. Y., has issued a very complete catalogue devoted exclusively to steam hammers. This company makes a specialty in 10 sizes, from 250 lbs. to 1600 lbs. falling weight. These hammers are in use in practically every part of the country and in foreign countries as well, and their field of use is constantly increasing. They are especially adapted to the use of manufacturers of electrical machinery. The catalogue fully describes and illustrates these hammers, and gives all the dimensions of each.

NATIONAL ALTERNATORS.—The National Electric Company, Milwaukee, Wis., has recently issued a 40-page pamphlet on the subject of its alternating-current machinery for lighting, power and railway service. The National Company has developed a line of revolving field alternators up to 1500 kw capacity. These machines represent the latest development of engineering design, and both the mechanical and electrical features have been carefully worked out. Their construction and features are completely described and clearly illustrated. Tables and diagrams at the back give the principal dimensions of the machines of the various types.

A HANDSOME CALENDAR, quarto size, has been issued by the Stromberg-Carlson Telephone Manufacturing Company, of Chicago and Rochester, N. Y. It shows a beautiful girl in evening dress sitting at a desk telephone set of the company's make, receiving very pleasant news, transmitted evidently with very distinct articulation. A special feature is the fact that the picture is not a "half-tone," but a real photograph. At the side is a large rose spray with the flowers and leaves in natural colors. The monthly calendar slips are detachable. Copies of this artistic calendar can be had on application by the heads of telephone operating companies, the request to be accompanied with 10 cents for mailing.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED MARCH 29, 1904.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St. N. Y.]

755,054. SERVICE-METER FOR TELEPHONE-LINES; Charles E. Scribner, Chicago, and Frank R. McBerty, Evanston, Ill. App. filed April 2, 1900.

755,127. ELECTRIC SELECTIVE SYSTEM; Juliene Auguste Géhrung, St. Louis, Mo. App. filed February 8, 1902.

755,308. SERVICE-METER FOR TELEPHONE-LINES; Frank R. McBerty, Evanston, Ill. App. filed July 16, 1900.

755,515. COUNTING SYSTEM FOR TELEPHONES; Johann Heinrich Meyer, Madgeburg, Germany. App. filed May 26, 1902.

755,630. BELL; William W. Dean, Chicago, Ill. App. filed March 24, 1902.

755,642. ELECTRIC ACCUMULATOR-PLATE; Chaimsonovitz Prosper Elieson, Paris, France. App. filed Oct. 16, 1903. (See Current News and Notes.)

755,643. PROCESS OF MAKING ELECTRIC ACCUMULATOR-PLATES; Chaimsonovitz Prosper Elieson, Paris, France. App. filed Oct. 16, 1903. (See Current News and Notes.)

755,646. MULTIPLEX TELEGRAPHY; Stephen D. Field, Stockbridge, Mass. App. filed March 5, 1903. Current reversals and currents of different strength are transmitted by a single mechanism so arranged as to act without interference and in transmitting the reversals the potentials are altered by a series of steps between the maximum of one polarity and that of the opposite, thus making it easier to "balance" the system. Two other transmissions are superposed upon the first two by giving different frequencies to a vibratory key.

755,647. MULTIPLEX TELEGRAPH; Stephen D. Field, Stockbridge, Mass. App. filed March 24, 1903. Improvements upon the preceding invention.

755,659. ELECTRIC WATER HEATER; James F. Hathaway, San Francisco, Cal. App. filed Aug. 10, 1903. A handle having a heater attached thereto and adapted to be plunged into a vessel of water.

755,669. CURRENT SELECTOR FOR CHARGING SECONDARY BATTERIES; Miller R. Hutchison, New York, N. Y. App. filed May 5, 1903. An electrolytic cell adapted to permit the flow of current in one direction but to prevent it in the opposite direction, is placed in circuit with the battery and a lamp for charging purposes, the lamp showing when the current is flowing to the battery.

755,697. ELECTRIC INCANDESCENT LAMP SOCKET; Guy H. Proctor and John B. Daley, Somerville, Mass. App. filed 30, 1903. Details.

755,708. HIGH OR LOW PRESSURE SIGNAL ALARM; Frank H. Schmitz, New York, N. Y. App. filed Sept. 4, 1903. A plunger is forced upward by the fluid pressure and closes a circuit at a critical point.

755,731. CONTROLLER FOR ELECTRIC MOTORS; Magnus W. Alexander, Lynn, Mass. App. filed June 13, 1903. When current fails or drops below a certain strength, the contact arm of the controller is automatically disconnected from the hand lever and returned to its off-position.

755,732. ELECTRIC MOTOR; Ralph E. Barker, Lynn, Mass. App. filed Aug. 7, 1903. The weight of the field coil is sustained upon lugs projecting from the head castings of an inclosed motor.

755,739. MAXIMUM DEMAND INDICATOR; Harry W. Brown, Boston, Mass. App. filed Aug. 2, 1902. The indicator comprises a conductor which is magnetic at low temperatures but non-magnetic at high temperatures; a variation of magnetism causes an indication on a scale.

755,740. SYSTEM OF ELECTRICAL DISTRIBUTION; Harold W. Buck, Niagara Falls, N. Y. App. filed Sept. 4, 1902. A motor generator set having means for regulating the voltage on the alternating current system in response to variation of load on the direct current system.

755,743. REMOVABLE CONTACT FINGER TIP; Frank E. Case, Schenectady, N. Y. App. filed July 9, 1902. The tip is separate from the finger and formed to be readily attached and detached.

755,744. CONTROLLER; Frank E. Case, Schenectady, N. Y. App. filed Oct. 1, 1902. An elongated coil is arranged across the face of a controller drum so that its field of force includes all of the arc gaps, a single coil thus serving to disrupt arcs at any point on the controller.

755,757. MULTIPLE RATE METER; Alexander J. R. Fiego, Lynn, Mass. App. filed July 21, 1903. Two dial-trains are alternately connected with the meter-motor by electro-magnets whose circuits are closed by a clock.

755,766. TRANSFORMER; Walter A. Hall, Lynn, Mass. App. filed Sept. 29, 1902. A transformer core consisting of oppositely disposed bundles of iron laminæ arranged radially to fill the center of the core with a mass of laminated iron polygonal in cross-section to form cooling spaces in the periphery of the center of the core.

755,771. ELECTRIC SWITCH OR CIRCUIT BREAKER; Edward M. Hewlett, Schenectady, N. Y. App. filed Jan. 29, 1900. Mechanism for operating the circuit breaker from a point of safety to the operator.

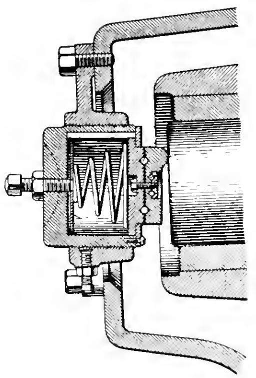
755,772. SWITCH; Edward M. Hewlett, Schenectady, N. Y. App. filed Aug. 14, 1903. Means for closing the field circuit of a generator through a resistance shunt, comprising a snap switch and an auxiliary shunt terminal on which said switch closes just before opening the armature circuits.

755,774. ELECTRIC CLOCK; Frank Holden, London, England. App. filed April 16, 1900. Details.

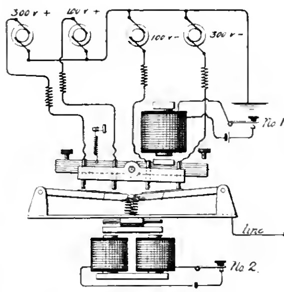
755,775. SYSTEM OF ELECTRICAL DISTRIBUTION; Lewis L. Holladay, Lynn, Mass. App. filed Aug. 21, 1902. A plurality of secondary coils on a transformer, one feeding a circuit with lagging current and the other feeding a consumption circuit with leading current.

755,782. ELECTRICAL CONTACT DEVICE; John Lindall, Boston, Mass. App. filed Oct. 8, 1903. A third-rail contact shoe consisting of a box-shaped piece of metal resting at its extremities against a leaf spring to prevent free movement or rattling.

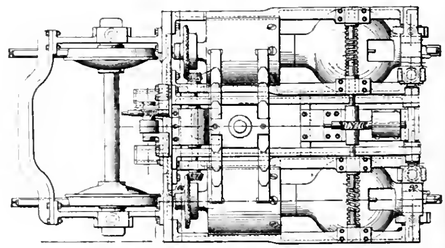
755,783. ELECTRIC FIRE ALARM; August Lueckert, St. Louis, Mo. App. filed Dec. 10, 1902. Details.



755,787—End Play Device for Rotary Machines.



755,646—Multiplex Telegraphy.



755,905—Electric Traction System for Railways.

755,787. END PLAY DEVICE FOR ROTARY MACHINES; David Miller, Schenectady, N. Y. App. filed Aug. 20, 1903. A disk having a boss which rests against the end of the shaft is mounted to rotate upon a thrust plate mounted in a plane oblique to the end of the shaft.

755,791. MEANS FOR CLOSING FIELD CIRCUITS OF ROTARY CONVERTERS; William B. Potter, Schenectady, N. Y. App. filed Sept. 17, 1903. By means of a polarized armature the proper polarity of the armature brushes at the instant the field is connected to them, is ensured and by a proper adjustment of a spring the voltage at which the field circuit will be closed can be adjusted, thus the danger arising from closing a field circuit at the wrong instant is avoided.

755,793. STARTING DEVICE FOR INDUCTION MOTORS; Henry G. Reist and Arthur W. Henshaw, Schenectady, N. Y. App. filed June 27, 1902. The invention consists of a motor starting device comprising a starting switch having contacts carried by the rotable member, and an operating mechanism, arranged to give a step-by-step movement to the switch in one direction, the mechanism being also arranged to permit a continuous movement in the reverse direction.

755,796. FUSIBLE CUT OUT; Howard R. Sargent, Schenectady, N. Y. App. filed March 14, 1900. A fusible strip is placed in an air-tight strong cartridge, otherwise empty, so that the gases evolved by the blowing of the fuse will not destroy the cartridge.

755,797. ARC LAMP HANGER; Howard R. Sargent, Schenectady, N. Y. App. filed Sept. 2, 1902. An automatic hook which engages when the lamp is lifted and disengages by a slight upward movement.

755,800. TRANSFORMER; Louis M. Schmidt, Lynn, Mass. App. filed Sept. 19, 1902. A transformer having portions of its core extended beyond the body of the transformer to form supporting feet and a winding surrounding the core except near the feet, the terminals being brought out in the unwound space.

755,814. COUPLING ELECTRIC MOTORS; David P. Thomson, Rugby, England. App. filed Sept. 8, 1903. Unison running is accomplished by connecting corresponding fixed points in the armature winding by equalizing connections of such a character that only equalizing current will flow through them.

755,815. ELECTRIC ARC LAMP; Elihu Thomson, Swampscott, Mass. App. filed Aug. 19, 1901. A self-induction coil in series with the arc, a polarized armature connected with a movable carbon and a closed coil operating to assist the movements of the armature.

755,819. INDUCTION MOTOR; Pendleton G. Watmough, Schenectady, N. Y. App. filed Sept. 2, 1902. The stator has a two-part ring-core over which the coils are slipped and then an externally slotted ring is passed into the ring-core so that its slots will embrace the sides of the coils and produce, in effect, a "tunnel" winding.

755,822. TRAIN CONTROL SYSTEM; George Whittlesey, Washington, D. C. App. filed Sept. 26, 1902. A multiple train control system in which the standard car controllers are utilized and the number of train wires reduced to four.

755,824. MEANS FOR STARTING ALTERNATING CURRENT DYNAMO ELECTRIC MACHINES; Jonathan E. Woodbridge, Schenectady, N. Y. App. filed Sept. 11, 1901. Comprises means whereby an electro-motive force of gradually increasing frequency can be impressed upon the machine to be started and also means whereby the field of a machine can be excited by a direct current.

755,825. RAILWAY BRAKE APPARATUS; Granville T. Woods and Lyates Woods, New York, N. Y. App. filed Dec. 31, 1902. The invention comprises various ways of bringing a train to a stop, controllable either by the motorman, or self-acting in case he is disabled; or by a passenger, or by a flag-man at the roadside.

755,827. RHEOSTAT; William C. Yates and Paul Zimmer, Schenectady, N. Y. App. filed July 25, 1903. A rheostat by which resistance may be cut into a circuit in large steps until near the desired amount and any large step then graduated by small steps for more exact regulation.

755,828. RHEOSTAT; William C. Yates, Schenectady, N. Y. App. filed Aug. 22, 1903. Details.

755,829. CONTROLLING INDUCTION MOTORS; Arnaldo P. Zani, Milan, Italy. App. filed June 30, 1900. (See Current News and Notes.)

755,830. TUB FOR ELECTRIC BATHS; Jcself Zwiebel, Neu-Ulm, Germany, App. filed Nov. 24, 1903. Rods supporting the electrodes have insulated portions to which the electrodes can be transferred to alter the number in circuit and accordingly the direction and strength of the current.

755,840. DETECTOR FOR ELECTRICAL DISTURBANCES; Jagadis Chunder Bose, Calcutta, India. App. filed Sept. 30, 1901. (See Current News and Notes.)

755,853. ELECTRIC-POWER-TRANSMISSION SYSTEM; Max Deri, Vienna, Austria. App. filed May 28, 1902. (See Current News and Notes.)

755,889. ELECTRIC RAIL BOND; Jang Landsing, Brooklyn, N. Y. App. filed April 25, 1900. A strap of metal slitted into narrow strips between its extremities, the strips being bent at succeeding points to afford the necessary flexibility.

755,890. ELECTRIC SIGNALING DEVICE; Thomas C. Laney, Toledo, and Charles S. Longnecker, Delta, Ohio. App. filed Nov. 24, 1902. Details.

755,897. ELECTRIC LOCK; Frank Lombardi, Brooklyn, N. Y. App. filed Dec. 19, 1903. Details.

755,899. ELECTRIC RAILWAY SYSTEM; Timothy Mahoney, San Francisco, Cal. App. filed April 20, 1903. Details.

755,905. ELECTRIC TRACTION SYSTEM FOR RAILWAYS; August Meuschel, Montreal, Canada. App. filed May 4, 1903. The driving means instead of being cylindrical like car wheels, are spherical in form and rotate in variable planes, parallel to the line of motion of the car, so that the effective diameter of the driver can be altered without altering the speed of rotation of the driver.

755,954. ELECTRIC LAMP AND SOCKET; Albert N. Soden, Trenton, N. J. App. filed Dec. 10, 1902. The lamp is an inverted cone in shape and has an outer transparent wall and in inner reflecting wall, a number of filaments embracing the latter and being singly or jointly insertable in the circuit by a suitable switch.

755,999. ELECTRIC TROLLEY HEAD; John T. Cherry, Plymouth, and Edward H. Clive, Devonport, England. App. filed Nov. 3, 1902. Details.

756,025. ELECTRIC LIGHT CIRCUIT PROTECTOR; Stanley Kalbach, Wildwood, N. J. App. filed May 12, 1902. Details.

756,026. INSULATOR; William S. Kinsley, Stewart S. Bell, Reading, Mass. App. filed Aug. 10, 1903. A two-part block carrying the conductor between them and held together by a binding wire, the block being supported by a bail having a threaded shank.

756,045. SHUNT CONTROLLER FOR ELECTRIC MACHINES; Nels O. Nelson, Chicago, Ill. App. filed July 13, 1903. The output of a frictional generator is controlled by means for forming a shunt circuit between inductor bars arranged adjacent to the collecting combs.

756,049. SWITCH FOR INCANDESCENT ELECTRIC LAMPS; Conrad M. Pitel, Meriden, Conn. App. filed Nov. 23, 1903. A switch designed for hanging lamps.

756,050. COUPLING FOR INCANDESCENT ELECTRIC HANGING OR SUSPENSION LAMPS; Conrad M. Pitel, Meriden, Conn. App. filed Nov. 23, 1903. Details.

756,091. TELEPHONE-CABINET; William B. Altick, Lancaster, Pa. App. filed May 16, 1902. (See next week's issue.)

756,117. ELECTRIC LAMP SUPPORT FOR CONVERTIBLE SIGNAL LANTERNS; Louis H. W. Kerber, Chicago, Ill. App. filed May 13, 1903. A framework arranged to receive either an electric or an oil lamp.

756,119. ELECTRIC RESISTANCE; Hans Von Kramer, Bath, England. App. filed Sept. 1, 1903. Details.

756,156. SIGNAL APPARATUS FOR TROLLEY RAILWAYS; Almo L. Cheatham, Louisville, Ky. App. filed Aug. 8, 1903. A contact arranged to be touched by the trolley wire when it lifts the main conductor in passing.

756,167. CONTROLLING ELECTRIC BOOSTERS; Edward M. Hewlett, Schenectady, N. Y. App. filed Oct. 20, 1902. An auxiliary booster is provided and adapted to be inserted in place of an incapacitated booster feeding any one of a number of circuits.

756,176. PROTECTIVE SHEATH OR ENVELOP FOR STORAGE-BATTERY PLATES; Achille Meygret, Paris, France. App. filed March 29, 1904. (See Current News and Notes.)

756,181. INSULATOR; Louis McCarthy, Boston, Mass. App. filed Feb. 11, 1904. Oppositely placed metallic portions connected by a piece of insulating material and surrounded by a molded insulating composition, the latter being formed with a number of petticoat edges.

CONTENTS.

FEASIBILITY OF PIPE GALLERIES.

The serious accident and fire which occurred last week at Fulton Street and Broadway, New York City, throwing out of operation for some time thousands of telephonic and telegraphic circuits, must necessarily revive discussion as to pipe galleries and the best means of preventing such accidents. The manner in which Broadway has been excavated for the underground road has foreboded some such disaster as this, more particularly because the electrical cables have been deprived of their wonted conduit protection. As a matter of fact, this accident has been regarded as an argument in favor of pipe galleries, but it seems to us that this is a view of the case hardly justified by the facts. If these telephone and telegraph cables had not been disturbed from their normal location, they would have been enclosed in the usual fire-proof brick manhole and in fire-proof ducts. The cables would have been stood neatly against the walls of the manhole and would not have been surrounded by inflammable burlap and by the mass of woodwork which fed the flames. Now, in most of the pipe gallery schemes which have been discussed from time to time, the plan has been broadly that of carrying the cables in masses through an open tunnel, thus exposing them throughout their entire length to the danger of just such an accident as that which has occurred and which will inevitably occur again unless greater care is taken.

Another view of the pipe gallery question suggested by this accident brings up, apparently, a danger of the first magnitude. If in such galleries there should also be carried with the electrical conductors enormous gas and water mains with their various connections, the liability to fire, flood and explosion would appear to be seriously enhanced. With a big gas pipe broken, the gas rushing forth in vast volume and mixing with the air in the pipe gallery would, if ignited, as it undoubtedly would be, cause a pretty lively concussion. A sensational Sunday journal might easily depict without a great strain of the plausibilities an explosion the whole length of Broadway under such conditions, tumbling into the street like a pack of cards the sky-scrapers with which it is lined. On the other hand, the bursting of a water main might drown out like a lot of rats the passengers in nearby subway trains before they could be extricated.

At first glance, the pipe gallery idea has many recommendations, particularly in the ready accessibility of the various services and the facility with which new services can be installed, thus, for example, rendering new competition feasible, which to-day does not appear easy to effect. On the other hand, it does seem as though in working out a pipe gallery scheme, the first consideration should be given to dividing up the services rather than bunching them, so that as in a sectional water-tube boiler, the danger would be lessened rather than increased. The grave financial, legal and other problems of the gallery are, moreover, to be borne in mind before any such plan could be adopted, and the subject is well worth the closest consideration that the best engineering minds can give it. At first glance the pipe gallery appears to be a ready solution of many troubles, high in the list of which is the present abominable and incessant ripping up of the streets. On the other hand, as this accident of last week suggests, it is most desirable that the remedy should not be worse than the evil attacked

Transformers Efficiency Curves.

Elsewhere we print an article by Dr. Kennelly which embodies an elegant treatment of the subject of constant-potential transformer efficiency. Assuming that the excitation losses are constant—which assumption appears entirely valid within practical limits—it is shown that, having the test curve of a transformer, by a simple geometrical construction, the relation between, and the values of, the several factors of loss may be readily determined. This follows from the demonstration given that at the point of maximum efficiency the excitation and I^2R losses are equal, and at this point the drop of pressure in the transformer resistance is half the drop of efficiency. These conclusions follow from the fact established that, under the above assumption, the efficiency curve of a constant-potential transformer is an acute hyperbola, having for one of its asymptotes a straight line representing only the copper loss. It is to be hoped that Dr. Kennelly will publish the application of this treatment to the case of constant-potential shunt motors and generators even if, as stated, the limits of accuracy are less; for it will have much value in putting in a new light the fundamental principles of such apparatus.

An Example in Line Design.

Mr. Wiley's brief article on another page is a capital sample of the art of line calculation under rather trying conditions. It is very seldom that a construction such as described is necessary or justifiable. In the first place, 250 volts is a pressure seldom to be advised for a motor distribution in large units; and in the second place, it is extremely unusual to be obliged to go to the long span construction with so heavy cables as in this case. However, given the conditions there was nothing for it but to go ahead and run the spans, and this seems to have been done in a very workmanlike manner. The only thing which we should be disposed to call in question is the sufficiency of the factor of safety considering the use of material having a rather low and uncertain elastic limit. We hope that some one competent for the work will take up the investigation of the elastic limit of electrical aerial conductors, with particular attention to the elongation factor. Aluminum has very obvious advantages for long span work by reason of its small weight and relatively good conductivity, yet from all the data now at hand we should hesitate to use it with quite the same factor of safety used for copper. However, in this case the proof of the pudding is in the eating and a few seasons of storms will show whether the strain is a little large for the elastic limit or not. One thing we hope Mr. Wiley will follow up carefully, and that is the actual as compared with the theoretical deflections. The expansion of wires under considerable tension has been very inadequately studied, and the behavior of aluminum cable under this condition is extremely well worth investigating. The sag of a long catenary is a wonderfully sensitive index of the coefficient of expansion, the temperatures are easily obtained from resistance measurements, and the resulting data are highly desirable. On many transmission circuits the use of long spans is being considered to cheapen line construction and to lessen the number of insulators. Aluminum is the material usually chosen for such constructions, hence an exact knowledge of its behavior under practical conditions is really important. We trust Mr. Wiley will make good use of his opportunities and take regular deflection measurements at intervals through the next year. The results will be most instructive.

The Preparation of Material for Standard Cells.

Two interesting papers presented last week before the American Electrochemical Society, the one by Profs. Carhart and Hulett, the other by Dr. Wolff, deal with the precautions that are necessary in order to insure electrochemically pure mercurous sulphate. A substance such as mercurous sulphate may be defined as being electrochemically pure, when its electromotive force is zero with respect to the same substance chemically pure. In order to procure electrochemically pure mercurous sulphate, the authors of both papers arrived independently at methods identical in all essential points. They use a process for producing the crystals at the anode. This is just the reverse of the ordinary method of depositing metals from salts. Profs. Carhart and Hulett went further and prepared and tested cadmium cells in which the electrolytic mercurous sulphate was used. Judging from the results reported in the manufacture of cadmium standard cells using the electrochemically generated mercurous sulphate, the authors are to be congratulated on their success. Some extended experience will, however, probably be needed before the final success of the method can be determined. The saturated solution cadmium cells thus produced appear to have an e.m.f. of 1.01908 international volts at 21.1° C. This is an e.m.f. of six significant figures. If we can even get four digits quite correct we can afford to smile gently upon the fifth and sixth, so far as concerns ordinary industrial requirements.

Weak Spots in the Patent System.

Our American patent system is, on the whole, perhaps as good as any other, yet one cannot have much personal experience with it or long watch its operations without realizing that it has some serious failings. To one of these we referred recently, namely, the practice of granting patents on current engineering development. Another conspicuous defect is the absence of any provision compelling the patents to be worked even in the most perfunctory fashion. Of course, this failing seems to be in the direction of liberality toward the poor inventor, but we very much question whether in the long run this apparently benign provision works to the inventor's benefit. At the present time almost every class in the Patent Office is rich numerically, in inventions. An attempt to work up the state of the art in almost any line discloses large numbers of more or less conflicting patents running back over a long term of years. Of these very few are fundamental in their bearing upon the art. Most of them are interlinked with their predecessors in a more or less complicated fashion and belong in the category of improvements. But of the whole mass of patents, primary and secondary, only a very small percentage have any record of practical usefulness. The vast majority is composed of patents unsuccessful and entirely unworked, or of patents taken out for purely defensive purposes, and never seriously intended to be worked. The result is that the inventor honestly striving to produce an article of industrial importance continually finds his way blocked by prior patents touching his invention, more or less remotely, but still sufficiently in the way to hinder material improvements or to control them if made. Even if the way be not completely blocked, it is so far obstructed as to make it difficult to get proper claims, or even claims sufficient actually to protect the new invention. How to avert this trouble is a very serious problem.

We are more than half inclined to the opinion that some requirements for working should be introduced in our patent system at the first opportunity for the purpose of giving the public and particularly inventors of improvements a fair show. The technical working required in some countries abroad is altogether insufficient since it is only necessary to go through the motions without really doing anything by which the public can benefit. Something considerably more drastic in the way of a remedy is needed to really put the unused patents and those held up for litigious purposes finally out of action. We should almost be inclined to favor a primary term of not more than seven years, followed by a reissue for a similar period on the presentation of evidence sufficient to show to the office that the invention is actually being manufactured and sold in the open market in good faith and in quantities sufficient to adequately meet current demands. At the expiration of this reissue term, a second similar reissue might be permitted after a somewhat more stringent inquiry. In case reissue were denied the patent would simply go out of existence and the invention would at once become public property. Such a scheme would eliminate all the dead failures and most of the patents held for obstructive purposes, either on paper or in reality, and would clean the way for improvements. It would obviously have been made, if in existence, to clear up some of the most celebrated tangles of recent years, and it would certainly tend to lessen the mass of fruitless litigation that now burdens our patent system. It, of course, throws heavy responsibility on the officials in charge and opens the way for some perhaps questionable decisions, but after all we have to depend on the office for the original patents themselves and for the present reissue system, and the responsibility is seldom abused. With the immense mass of patents that has been accumulating some sort of relief is absolutely necessary if the march of improvement is to continue unobstructed. The details of any proposed system of relief naturally require to be worked out with great care, and we are far from proposing a simple panacea to meet all cases; yet some means ought to be provided for getting unused and unsalable patents out of the way without waiting seventeen years for them to die of old age.

MOLECULAR CONDUCTIVITY.

In a paper presented last week before the American Electrochemical Society, Mr. C. J. Reed attacks the definition and customary text-book enunciation of "molecular conductivity." There is certainly force in Mr. Reed's argument. It seems indisputable that the definitions and statements current in electrochemical text-books relating to "molecular conductivity" are loose, and out of conformity with the definition and statements adopted in physics for conductivity. It is very desirable that this evil should be eradicated and electrochemical dicta brought into conformity with those of general physics. On the other hand, Mr. Reed, after demolishing the theoretical basis of the term "molecular conductivity," as used by electrochemists, takes the position that all theoretical deductions based on investigations of "molecular conductivities" have no physical significance. By this we suppose he means that they are scientifically meaningless, valueless and heretical. Here we have to differ with him. We think he goes too far when, after hacking the definition to pieces, he throws overboard the whole idea framed in the definition. As usual in such cases, it is a matter of language. We think the ideas are valuable, represent important scientific facts and should be carefully preserved. The language of the definition is at variance with physical terminology, and since the latter is to be regarded as of earlier foundation and logically sound, the more modern electrolytic phraseology should be amended in such a manner as to conform therewith.

In electromagnetics, a resistance is a quantity that in absolute measure must be expressed in absohms, or the units which may be called absolute ohms; while in practice it is measured in units a billion times as big; i. e., in ohms. Resistivity is a specific property of matter in regard to resistance when referred to unit dimensions, and may be defined as the resistance of a unit cube of the substance between opposed parallel faces. Such resistivity to be in absolute measure, must be expressed in absohm-centimeters; or, if expressed in practical measure, must be in ohm-centimeters. Conductivity is the reciprocal of resistivity, and, in absolute measure, must find expression in abmhos per centimeter, or the units implied thereby; while in practical measure it must be in mhos per centimeter. The conductivity of a homogeneous material may be defined as the conductance of a unit cube of the material between any pair of opposed faces. Of course, no man can be compelled to express the conductivity of sea water in the units above-named. He may express his conductivity in terms of the conductivity of mercury (at a standard temperature), for example. It would be perfectly correct to do so; but it would not be the international physical system of measurement, which is the C. G. S. system. In the C. G. S. magnetic system there is one and only one unit for any one physical quantity, and conductivity must, in that system, be measured in terms of the unit which we have described as the abmho-per-centimeter. This name is open to dispute, but the unit is beyond dispute. In precisely similar fashion we may express the velocity of light in any definite unit that we please, such, for example, as cubits per hour; but if we state it in the international physical system there is one and only one unit—the centimeter per second.

Electrochemists theoretically determine molecular conductivities of solutes in aqueous solutions by taking a thin tank of glass, the side walls of which are parallel, vertical and 1 cm. apart. They electroplate or apply electrodes to these walls, so as to have the electrodes parallel, vertical and 1 centimeter apart. Whatever the density of the solution to be tested may be, they pour in enough of the solution to contain one gram-molecule of the solute. For example, with potassium chloride solution, they pour in as much as contains 74.5 grams. They then measure the conductance of the electrolytic cell and express it in terms of the conductance of a prism of pure standard temperature mercury—1 meter long and 1 sq. mm. in cross-sectional area. They call the result the molecular conductivity of the solution for that particular dilution. Of course, we do not mean that the process is actually conducted in the above manner, but we believe that it may be properly conceived of as being so executed. There is nothing in all this to criticize except the definition. What is measured is essentially a conductance multiplied by an area, expressed in absolute measure in abmho-sq.-cms.; or in practical measure in mho-sq.-cms. It is not consistent with electrics or the electrical department of physics to call the quantity arrived at a "conductivity." If it is called a conductivity, then this conductivity is inconsistent with the ordinary conductivity of electrics, a quantity which can only find expression in the absolute unit that we may call an absohm-per-centimeter.

The quantity which the electrochemists derive is a conductance multiplied by an area, or a conductivity multiplied by a volume. The same quantity may in fact be derived by measuring the resistance (between parallel faces), of a cubic centimeter of the solution, determining the corresponding conductivity in mercury units, and then multiplying by the volume of solution in cubic centimeters which would contain a gram-molecule. The quantity is, therefore, correctly expressed in current physical terms, either as a conductivity volume, or a conductance area. In absolute measure it must be expressed in the unit which may be called an abmho-square-centimeter. But whatever this unit be called, it is the only unit which can be used if we are to keep in the international C. G. S. system. No particular harm is done by calling the quantity a molecular conductivity, until we begin to think about conductivities as defined in the ordinary way, and then a clash becomes inevitable. No error would be involved if the quantity were rechristened "molecular-volume-conductivity," or "molecular-conductivity-volume." All propositions now enumerated concerning molecular conductivities could then be made concerning molecular volume-conductivities without any danger of inconsistency. In any case it seems unnecessary to retain the old Siemens mercury unit, or the specific resistance of mercury, in the definition. It may be troublesome to reconstruct tables which have been laboriously prepared in terms of mercury, but after all, part of the business of construction is reconstruction, and the old order giveth place to new. The pride of science lies in its junk heap.

British Views of American Technical Education.

In a cable account of the report of the Mosely Education Commission, which recently visited this country—which consists of a large volume containing the separate reports of the twenty-six commissioners—the New York *Sun* says that the commissioners have much to say about the relations between education and industry, and the reliance of manufacturers on the schools for the best and brightest men, while the highly trained lads from the technical schools in England find difficulty in getting employment in a manufactory. The commissioners think that engineering students in the United States stay too long at school, and, according to Prof. Armstrong's view, overteaching is the bane of American schools of every grade.

Prof. Ayrton makes the following comparison of results: "The American student usually is not as scholarly nor as well read as the English student of the same age, but he has his knowledge in a better form to apply. The British system turns out a man full of knowledge and principles, while the American product is a business man with a scientific training. The characteristics of each nation have their advantages.

"To America we look for that rapid, bold and successful application of science to industry which has brought about the commercial invasion of the world; while to Europe we look for those scientific imaginings and creations which apparently are so unimportant to-day, but which to-morrow revolutionize old industries and give birth to new ones."

Mr. Blair, of the Irish Department of Technical Instruction, writes that the best ability in the United States is not to be found in the professions and in politics, as in Great Britain, but in the industries and in commerce.

Among the general conclusions are the following: That while education is not the prime cause of the remarkable progress during the last thirty years in America, it is a powerful contributory cause and the essential condition of its maintenance; that the root of educational progress in America and the secret of any superiority that its institutions possess lie in the good will of the people and the universal belief in the value of education, and that there is nothing like finality in American educational institutions any more than there is in the British.

Union Engineering Building.

In order to enable the three national engineering societies to avail themselves of Mr. Carnegie's gift of a building for headquarters and library purposes, etc., the conference committee has had drafted a bill incorporating what is known as the United Engineering Society to hold the property for the societies. This bill was introduced in the State Senate by Senator Townsend, of Utica, and has already passed both the chambers, and has gone to the Governor for signature this week. The bill is virtually a transcription of the act incorporating the Cooper Union, its purposes being in most respects, if not all, identical with regard to the public objects of the building.

The conference committee has also selected the following well-known firms of architects who have consented to join in a limited competition for the plans of the Engineering Building, as well as of the Engineers' Club, namely, Carrere & Hastings, Clinton & Russell, Whitfield & King, Ackerman & Partridge, Palmer & Hornbostel and Lord & Hewlett. The committee also expects this week to provide itself with a professional adviser whose assistance it will enjoy in connection with the architectural part of its work. In addition to the six competing firms, each of whom will be paid for its plans, there will be an open competition in which the leading competitors will be compensated by four prizes. It is believed that this mixed competition will furnish the committee with a wide range of desirable designs. Some of the best firms of architects do not enter these competitions, but it was Mr. Carnegie's wish that the matter should be put on this broad basis.

During the absence of Dr. S. S. Wheeler in Europe, Mr. Gano S. Dunn has been appointed by the American Institute of Electrical Engineers as its representative in his place on the conference committee. Mr. Dunn is a member of the Institute council.

Telegraphy in Central Africa.

Some details have been made public recently as to the telegraph line from the Atlantic shore of the African continent to Lake Tanganyika, a distance of about 1,500 miles, for which $600,000 was voted by the Congo authorities. The completed line thus far is only 750 miles long. It took about two years to construct the line from the sea to Stanley Pool, 450 miles. The crossing of wide rivers presented a tough problem. It was nearly a year before the wire was stretched across the widest river between Matadi and Stanley Pool. The river is nearly half a mile wide. Two steel poles were finally erected on hills 2,620 ft. apart. The posts are 50 ft. high and their tops are over 200 ft. above high water level in the river.

Above Stanley Pool to Equatorville, the present terminus of the line, the difficulties were still greater and nearly all the work was done by natives under the direction of Europeans. The most difficult piece of work was the crossing of the Kasai River, the second largest Congo tributary. It was necessary to keep the wire so high that it would not interfere with steamer traffic on the river. Fortunately, where it was desired to cross a rocky island stands in midstream. A high steel post was erected on the island and two others on the banks of the river, so that the crossing was made in two spans, one of 1,472 ft. and the other of 2,198 ft. The wire is suspended about 20 ft. above the smokestacks of the steamers. The posts to which the wire is attached are either of iron or living trees and, therefore, proof against the attacks of white ants; but elephants sometimes knock down the iron posts and every now and then storms throw down trees across the line. Communications are interrupted occasionally for hours at a time by electric discharges during the heavy tropical storms.

Among the minor embarrassments are birds, which make their nests on the wire; wasps, which settle in the insulators, and spiders, that cover the poles from top to bottom with their webs and collect a litter of leaves and twigs.

The line, however, is wonderfully facilitating business and is used both for telephone and telegraph service. Each telegraph station is protected by a squad of native soldiers.

Irrigation Plans in California.

Details have appeared in these pages from time to time as to the use of electric power in connection with pumping and irrigation in California. We now note a further development. A new co-operative water company, to be known as the Anaheim Mutual Water Company, is being started at Anaheim, Cal. Those materially interested in its formation and who will receive the greatest benefit as well as subscribe for the stock are a number of ranchers living between Anaheim and Buena Park. The new company, it is stated, has received sufficient support to assure its success, and the necessary agreements have been drawn up by local attorneys.

The plans provide for developing the water by means of pumping plants. The Edison Electric Company proposes to put down a series of wells in the territory to be covered, and agrees to develop 300 inches of water by June 15 next. Ranchers and others taking stock in the company are to make a deposit of 20 per cent. of the amount subscribed with the First National Bank, which is to be paid over to the Edison Company, together with the additional 80 per cent. Upon the development of the amount of water agreed upon the plant is to become the property of the Anaheim Mutual Water Company, the electric company merely furnishing the power after the plant is completed. The proposed plant will allow one-fourth of an inch of water to the acre, providing for 1,200 acres to be represented in the new company.

Institute Meeting.

The 186th meeting of the American Institute of Electrical Engineers will be held at the Chapter Room, Carnegie Hall, 154 West Fifty-seventh Street, New York, Friday evening, April 22, at 8.15 o'clock. The following papers will be presented: "The Mechanical Construction of Revolving-Field Alternators," by David B. Rushmore; "Contribution to the Theory of the Regulation of Alternators," by H. M. Hobart and Franklin Punga, of London, England.

New Radioactive Elements.

Prof. Charles Baskerville announced last week his discovery of two new radioactive elements in monazite sand from North Carolina. One he calls carolinium and the other Berzelium. These elements owe their development partly to the use of thorium dioxide, and have a higher power of luminosity. He showed the properties before the Chemists' Club. A cable dispatch from London quotes Sir W. Ramsay's prompt appreciation and approval of this work.

A Long-Span Transmission Line.

By B. Wiley.

The accompanying illustrations show a recently installed 250-volt direct-current power line from the Carrie Furnaces, situated on the Monongahela River, just below Braddock, Pa., to the Homestead Steel Works. The power house is directly back of the pole on the far side of the river, and the point of distribution about 500 ft. from the pole on the near side. The one particular feature is the excessive span adopted, the distance between supports being practically 1,000 ft.

When this problem of line construction was first introduced the three methods considered were as follows:

First, a pole line on the opposite side of the river from the power station to the bridge, shown on the right, across the bridge and down the river to the mill on the Homestead side. Second, a submarine cable system. Third, the present arrangement.

By rough calculation it was deduced that the latter was the most economical, simple of construction, and, from a general engineering standpoint, the most desirable. The span consists of four 800,000 circular mils aluminum cables anchored to steel structural towers on either side of river. These towers are of heavy material and securely braced by four 1¼-in. tie rods. They were made and erected by the Homestead Steel Works. Fig. 1 gives a general arrangement view of the lines, and shows location and height of the towers. The details of attachment of cable to the towers are shown in Fig. 2. The cables were cut to the required length and furnished with aluminum sleeves, *A*, which were clamped to the cable under hydraulic pressure. These sleeves on opposite ends are threaded right and left hand, respectively, and fit copper clevice bolts, *B*. *C* is a steel forging and *D* a strain insulator. *E* is a steel tension bolt for adjustment of sag and *F* represents portion of tower. The leads to and from the cable are flexible stranded wire, and the connection was made by flaring the ends, wrapping them about copper clevice bolts, *B*, and then soldering.

The following extract from Foster's Handbook, as quoted from a publication of the Pittsburg Reduction Company, sets forth very plainly the advantages to be derived in this particular case, by the use of aluminum in preference to copper cables; and the preceding material was selected:

"Aluminum wire, rods and bars will be furnished of 63 per cent. electrical conductivity, which will have an equal tensile strength per unit of area with the copper, and, therefore, with the electrical conductivity equivalent of 48 per cent. of the weight of the copper and sectional area of 160, against the area of the copper section 100. The tensile strength of aluminum conductors will be as 100 for the copper is to 160 for the aluminum. This would mean, if a square inch of copper conductor was used of, say, 32,000 pounds per square inch tensile strength, the equal conductivity area of 1 6/10 in. of aluminum would have a tensile strength of 51,200 pounds.

"It has already been determined that with aerial lines the snow and ice load is practically as heavy on lengths of small wire as upon larger sections, so that no objections on this score can probably be found to the use of the larger section of aluminum wire.

"Both on account of having only 48 per cent. of the weight and on account of having about 60 per cent. more strength, the aluminum conductor could be used in much longer spans between supports and the number of expensive poles and insulators can be materially diminished."

The conditions that form the basis of the calculations are as follows: Line voltage, 250; load to be carried, 800 amp.; drop of voltage permissible, 40 volts; necessary size of copper conductor, 1,000,000 circular mils; necessary size of aluminum conductor, 1,600,000 circular mils; (duplicate lines of 800,000 circular mil cable were used for convenience of construction); maximum sag allowable at 212° F., 35 ft.; maximum wind probable pressure, 40 pounds per sq. ft.; minimum temperature, 20° F.; probable ice coating, ¼ in. thick. The tensile strength of hard-drawn aluminum wire is 35,000 pounds per sq. in.; its conductivity, 63, as compared with copper at 100; and the coefficient of expansion, .0000231 per degree Fahrenheit.

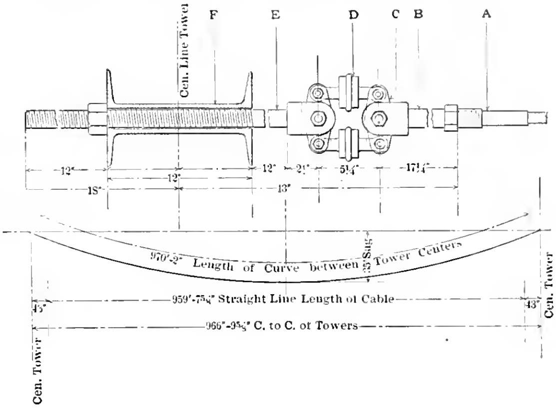

FIG. 2.—DETAILS.

The problem to be considered is, what is the maximum tension in the cable under the most severe conditions as noted above, as compared to the ultimate strength of the cable?

When a wire is suspended between two supports it takes a curve known technically as the catenary. In the case at hand, the catenary comes very close to the parabola, which gives the following relations:

$$T = \frac{L^2 w}{8 d} \qquad (1)$$

Where T = tension in cable at ends,
L = length of span in feet,
w = weight per foot of wire,
d = the central deflection in feet.

Obviously T will be a maximum when w is at its maximum and d at its minimum. The wire will have its greatest weight per foot when coated with ice and is withstanding a heavy wind pressure; and the deflection will vary directly as the temperature.

The weight of 1 ft. of 800,000-cm. Al cable	=	.736 lbs.
The weight of ¼ ft. ice coating per ft.	=	.389 lbs.
Total weight per ft.	=	1.125 lbs.

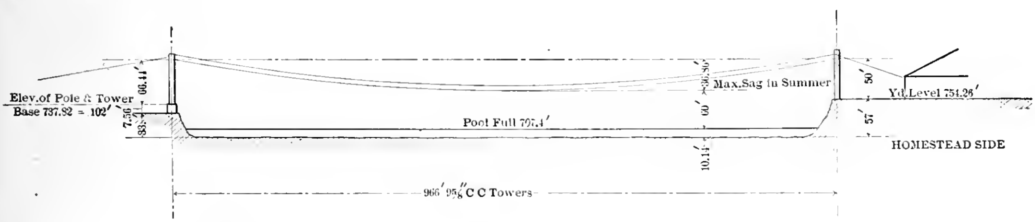

FIG. 1.—ELEVATION OF SPAN.

Taking the wind pressure at 40 pounds per sq. ft. and as acting on the cross-section of ice-covered wire, the pressure per foot is 4.166 pounds. As this force acts at right angles to the weight, the resultant force $= \sqrt{1.125^2 + 4.166^2} = 4.31$ pounds, which may be considered the maximum for w.

For the catenary curve, $L' = L + \dfrac{8d^2}{3L}$.

Where L' = actual length of cable,
L = length of span,
d = central deflection.

Transposing, $d = \sqrt{\dfrac{3L\,(L' - L)}{8}}$

From these two formulæ, d can be figured for any temperature, the initial sag being 35 ft. at 212° F. The following table gives the sag for temperatures between 212° F. and minus 20° F.:

Temp. F.°	Deflection Ft.
212	35.0
200	34.7
190	33.8
180	33.2
170	32.5
160	31.8
150	31.2
140	30.5
130	29.9
120	29.2
110	28.5
100	27.8
90	27.1
80	26.4
70	25.6
60	24.9
50	24.1
40	23.3
30	22.5
20	21.7
10	20.9
0	20.1
—20	19.2
—20	18.3

Substituting in equation (1) the values,
$w = 4.31$ pounds (the maximum weight),
$d = 18.3$ ft. (minimum deflection),
$L = 1{,}000$ ft.

$$T \text{ (the maximum tension)} = \frac{1{,}000^2 \times 4.31}{8 \times 18.3} = 29{,}400 \text{ pounds.}$$

The sectional area of 800,000-cm. cable is .8 sq. in., giving a tensile strength of $.8 \times 35{,}000 = 28{,}000$ pounds per cable. Comparing this result with the maximum tension, 29,400 pounds, it is seen that the line will not stand the severe conditions as set down. To relieve the strain, the line should be lengthened in the fall, and, to prevent excessive sag, taken up again in the spring.

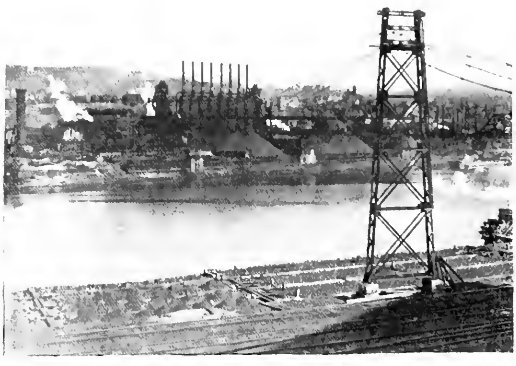

FIG. 3.—VIEW OF ONE TOWER AND THE LINE.

Suppose a range of temperature from 60° F. to — 20° F. be taken for the winter. Then the line could be allowed a drop of 35 ft. at this maximum temperature, which by reference to the table, would make the equivalent sag at — 20° F., 28.4 ft.

Substituting in formula (1),

$$T = \frac{1{,}000^2 \times 4.31}{8 \times 28.4} = 19{,}000 \text{ lbs.,}$$

or the one setting would give a safe tension on the cable for the conditions noted; though for severe conditions it would be well to give the maximum drop of 35 ft., as the adjustment requires only a few minutes' work.

As a summation, the maximum strain per cable is 19,000 pounds, or per tower, $4 \times 19{,}000 = 76{,}000$ pounds. The horizontal component due to the wind pressure is transmitted to the foundations and the direct pull to the steel brace rods behind.

The method of stringing the cables was very simple, and may be of some interest to the reader. The cables were wrapped on a large reel, which was set in a securely anchored frame, and arranged to revolve on a shaft. This equipment was placed on the near side of the river. It was provided with a brake, or rather sufficient friction to stop the reel as soon as the tension on the cable was released. The free end of the cable was passed through an ordinary snatch block hung at the top of the near tower. On the far side of the river, just back of the tower, was placed an electrical winch; and, from the drum a 1½-in. hemp line was passed through a snatch block at the top of the tower and carried across the river by a rowboat. The rope was fastened to the cable on the near side and pulled across by the winch, the boat supporting the end and thus being towed back for the return trip with rope for the next cable. When all but a few turns of the cable had been reeled off, a line was fastened a few feet from the end still on the reel. When the end reached the top of the tower, this line was used as a temporary anchor while the bolt was being placed. The 1½-in. line was replaced by a 2-in. line and sufficient slack was then taken up to allow the anchor bolt of the far end to be fitted into place. As these bolts were made extra long, there was still considerable sag in the cable; hence the tension was not great. The bolts were then adjusted to give the required sag. It was about 30 minutes' work to run a cable after starting it from the reel.

Streamers or Side Discharges from Electrodes.

By Alfred G. Dell.

In a former article on some of the phenomena of rotating discs, I stated that frequently streamers were seen coming from the electrodes under the discs. I propose to briefly describe some of their peculiarities.

They generally appear coming from one or the other of the zinc electrodes about ⅛ or ¼ in. back of the discharge point. Sometimes there are one or two discharges apparently coming from the inside edge of the electrode, and sometimes they seem to twist around the point. I have noticed that they often follow close to the metal and meet the point discharger, but sometimes they strike the disc, but always inclined towards the direction of the sparks from the points. I have never seen any inclined away from the sparks. It would seem there is some cause besides sharp edges or minute scratches or points, although scratches, etc., encourage their production.

I have tried various ways to prevent them, but have not succeeded entirely. Sometimes they will suddenly cease and there will be no more seen unless the arrangement is changed. I am inclined to think they always come from only one of the electrodes, and never from both. They are exceedingly thin, long discharges. In daylight nothing is seen of them, but in the dusk or dark, with the use of a lens, they are well seen with all their changes. When they strike the disc, they interfere with its rotations. If I knew why they should sometimes cease, I would more fully understand them.

It would be well for those working with an induction coil to be on the lookout for this phenomenon as its effects are injurious to the spark discharge. A low humidity in the boxes containing the discs reduces the effect and sometimes entirely prevents it, which I would suppose is on account of the conductivity of the air being reduced.

I have sometimes thought they might be capacity discharges from the windings of the secondary of the induction coil, something like the residual discharges from Leyden jars. The discharges taking place from only one electrode, be it plus or minus, would seem to strengthen that theory.

Municipal Electricians.

At a meeting of the executive committee of the International Association of Municipal Electricians, April 2, the following papers were assigned, to be read at the ninth annual convention to be held at St. Louis, September 13 and 14, 1904. "Street Lighting, Principles Involved and Systems Used," A. S. Hatch, Detroit, Mich.; "The Limitations of the Telephone for Fire Alarm Purposes," Adam Bosch, Newark, N. J.; "The Inspection of Theatres, from an Electrical Standpoint," Wm. H. Thompson, Richmond, Va.; "Methods of Testing," Walter M. Petty, Rutherford, N. J.

The Efficiency Curves of Constant-Potentia Transformers.

By A. E. Kennelly.

An alternating-current transformer of the ordinary constant-potential type consumes a certain amount of power at no load, or with open secondary circuit. This power, expended in the excitation of the transformer, is wasted in hysteresis and in eddy currents. The exciting current is usually so small a fraction of the full-load current that the I^2R losses, or copper losses, in the transformer coils at no load may be ignored.

Under load, it is assumed that the hysteresis and eddy-current losses remain unaltered. This is not quite correct; but it is sufficiently nearly correct for practical purposes. Consequently, the excitation losses may be regarded as constant, or independent of the load, and the loss which increases when the load increases is the copper loss, or I^2R loss, in the primary and secondary coils. Under sensibly non-inductive load, this I^2R loss increases as the square of the output.

Let Fig. 1 represent diagrammatically the windings of an actual

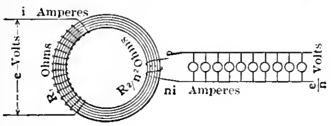

FIG. 1.

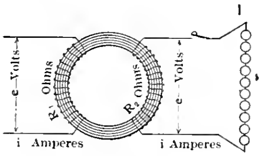

FIG. 2.

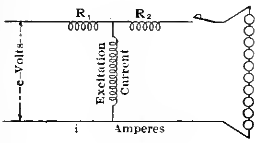

FIG. 3.

transformer, having a primary e.m.f. of e volts and a secondary e.m.f. of $\frac{e}{n}$ volts, where $\frac{1}{n}$ is the ratio of transformation. If R_1 be the primary resistance in ohms, the secondary resistance is $\frac{R_2}{n^2}$, where R_2 is the equivalent resistance of the secondary coil if rearranged with the same amount of copper, but with a number of turns equal to those in the primary winding. If i be the current in the primary coil, and the current of excitation is neglected, $n\,i$ will be the secondary current.

In Fig. 2 the same transformer is represented ideally as a level transformer, instead of a step-down transformer, the number of turns in the secondary winding being the same as in the primary. The e.m.f. in each circuit at no load is e volts. The current in each circuit under load is i amperes. The primary and secondary winding resistances are R_1 and R_2 ohms, respectively.

Fig. 3 gives the equivalent conductive circuit of the inductive system of Fig. 2. The two coils, R_1 R_2, are in series, while the current of excitation passes through a branch midway between them.

In the diagram, Fig. 4, the derived excitation circuit, with its p watts of constant loss, is separated altogether from the transformer, which is reduced to an equivalent resistance r ohms, delivering a current of i amperes under a pressure of e volts.

The efficiency n of the transformer, as represented by the system of Fig. 4, will be

$$n = \frac{e\,i - i^2r - p}{e\,i} \qquad (1)$$

where $e\,i$ is the input at primary terminals in watts, p the constant

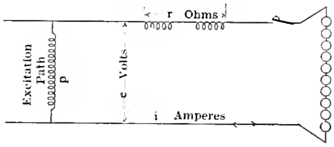

FIG. 4.

excitation loss in hysteresis and eddy currents (watts), while i^2r is the copper loss in both windings taken conjointly.

If n be plotted as ordinates to i as abscissas, we obtain the ordinary efficiency curve, such as that shown in Fig. 6, which is taken from the published data for a 2.25 megawatt transformer.*

This curve of n is a hyperbola. In other words, the efficiency curve of a constant-potential transformer with constant excitation, or frictional losses, is a hyperbola.

Equation (1) may be expressed in the form:

$$n = 1 - \frac{i}{I} - \frac{i_0}{i} \qquad (2)$$

where I is the current strength $\left(\frac{e}{r} \text{ amperes}\right)$ which would flow through the apparatus as represented in Figs. 3 or 4, if the secondary coil were short-circuited and the windings were devoid of reactance.

The current i_0 also represents the non-inductive current, $\frac{p}{e}$ amperes, which would expend, under the pressure e volts, a power p equal to the excitation losses.

In order to show that n in equation (2) represents a hyperbola, let us take the simple case of a transformer in which the constant primary pressure $e = 100$ volts, the total equivalent level resistance is $r = 1$ ohm, and the constant frictional loss is 50 watts. In this case $I = \frac{e}{r} = 100$ amperes; and $i_0 = 0.5$ ampere. Equation (2) becomes

$$n = 1 - \frac{i}{100} - \frac{0.5}{i} \qquad (3)$$

In order to elicit the geometrical meaning of this equation, let us first assume that the frictional loss is made to disappear, so that there is no loss of power in excitation.

Then
$$n = 1 - \frac{i}{100} \qquad (4)$$

This is the equation of a straight line. The straight line is shown in part at $A\,C\,D$ in Fig. 5, where the abscissas are amperes through the transformer assumed as level, and the ordinates are efficiencies. Following the line $A\,C\,D$ and taking 8 amperes (or 800 watts input) as the full load of the transformer, the full load efficiency will be 0.92, or 92 per cent. the efficiency at half load 0.96, etc. Similarly, the full-load drop in the transformer would be $1 - 0.92 = 0.08 =$ 8 per cent., and if the secondary pressure were 100 volts at no load, it would be 92 volts at full non-inductive load, disregarding phase relations. Consequently, if a transformer had no frictional loss, its efficiency would follow a straight line and the line of drop of pressure.

Next suppose, on the other hand, that the transformer has no resistance, but has the assigned excitation loss. Then equation (3) becomes

$$\eta = 1 - \frac{0.5}{i} \qquad (5)$$

This is the equation of a rectangular hyperbola. The hyperbola is shown in Fig. 5 by the dotted curve $E\,C\,F\,G$. Its asymptotes are the two rectangular, or mutually perpendicular, lines $A\,B$ and $A\,O$. On this assumption of negligible resistance, the half-load

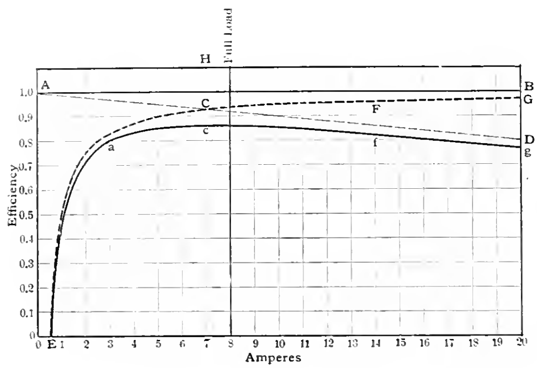

FIG. 5.

efficiency would be 0.875, and the full-load efficiency 0.938. The efficiency steadily increases, the portion $F\,G$ beyond F is very nearly a straight line, and the efficiency becomes nearer to 100 per cent. as the load increases.

If now the transformer possesses both excitation loss and resistance loss, as expressed in equation (3) the efficiency curve is the sum of the rectangular hyperbola and the straight line, or becomes

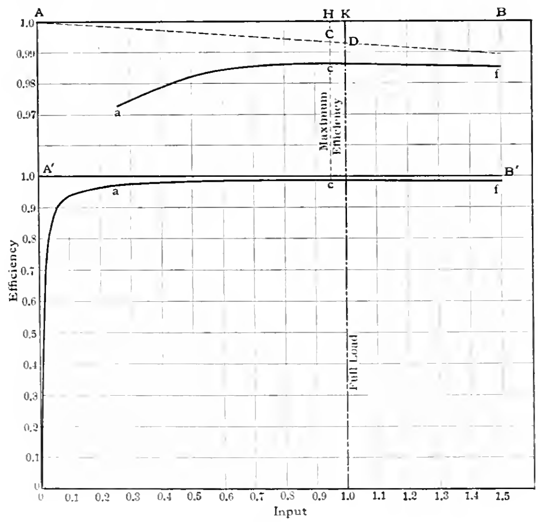

FIG. 6.

the acute hyperbola $E\,a\,c\,f\,g$, whose asymptotes are the straight lines $E\,O$ and $E\,D$.

On the hypothesis of resistance loss only, the efficiency continually diminishes with load along the straight line $A\,C\,D$. On the hypothesis of excitation loss only, the efficiency continually increases along the rectangular hyperbola, $E\,C\,F\,G$. With the actual transformer of virtually constant excitation loss plus resistance loss, the efficiency rises to a maximum on the acute hyperbola $E\,a\,c\,f\,g$, at the abscissa where the resistance line $A\,D$ cuts the hyperbola of pure excitation $E\,C\,G$. This intersection is at C and the maximum value of the efficiency lies immediately below it at c. Moreover, the intersection C lies midway between c, the point of maximum actual efficiency, and the straight line, $A\,B$.

Consequently, the resistance drop in the transformer at the point c of maximum efficiency is half the drop of c below the horizontal of 1.0, or 100 per cent. efficiency. Thus, in Fig. 5 the maximum actual efficiency at c is 0.8596, representing an efficiency defect of 0.1414, or 14.14 per cent. at a current of 7.07 amperes. The drop in resistance will, therefore, be $\frac{14.14}{2} = 7.07$ per cent. at 7.07 amperes, or corresponding to a resistance of one ohm.

Again, the percentage loss of power in resistance $C\,H$ is seen in Fig. 5 to be equal to the percentage loss of power in friction $C\,c$, at the point of maximum efficiency. Consequently, at the input of $100 \times 7.07 = 707$ watts, the efficiency defect of 14.14 per cent. represents $0.1414 \times 707 = 100$ watts, equally divided between 50 watts in friction (p), and 50 watts in resistance (I^2R).

The efficiency curve of a constant-potential transformer tells at a glance the amount of power expended in excitation, since this is half the power lost at maximum efficiency. It also tells at a glance the resistance drop in the apparatus, since the resistance drop is half the efficiency drop at the point of maximum efficiency.

As an example of these principles we may consider the efficiency curve of the transformer represented in Fig. 6. The curve in the lower part of the diagram is so nearly flat that it is difficult to point to the maximum; but by using an enlarged scale, as in the upper part of the diagram, it is easy to see that the efficiency reaches a maximum of 0.9865 at c, or 95 per cent. of full load. The efficiency drop is, therefore, 1.35 per cent. at this point, and the resistance drop following the straight line $A\,C\,D$ is $\frac{1.35}{2} = 0.675$ per cent. If this is the resistance drop at 95 per cent. of full load, the full-load resistance drop in the transformer, neglecting phase, is $\frac{0.675}{0.95} =$ 0.712 per cent., or $K\,D$.

The output at 95 per cent. of full load in a 2.25 megawatt transformer will be 2,140,000 megawatts. Half the efficiency defect at this maximum point, or 0.657 per cent., or 14,100 watts (14.1 kw), will be the excitation loss, and the remaining half will be I^2R loss at this load.

Summing up the above relations we have:

1. The efficiency curve of a constant-potential transformer is an acute hyperbola.
2. The point of maximum efficiency corresponds to equal excitation and I^2R loss, or equal losses in iron and copper.
3. The drop of pressure in resistance in the transformer at maximum efficiency is half the drop of efficiency.

It can be shown that these propositions also hold when the curve is drawn to output as abscissas instead of input.

Similar reasoning applies to constant-potential shunt motors and generators subject to somewhat greater limitations in accuracy.

The Evansville Municipal Telephone Scheme Illegal.

The Evansville Municipal Telephone Company's scheme has been declared illegal by a ruling of Judge Robison, special judge, in overruling the demurrer of the city in the suit by R. D. Richardson to enjoin the city from embarking in the municipal telephone business. The ruling practically disposes of the question.

Judge Robison held that the scheme is illegal because the preferred stockholders are allowed to name certain of the directors, which is contrary to the statute, and that the contract between the city and the telephone company is void because employees of the city are interested in the company as private stockholders. Immediately after the ruling by Judge Robison the directors of the Municipal Telephone Company held a meeting to discuss the status of affairs, but no definite action was taken. In legal circles the decision is regarded as a death blow to the municipal telephone idea in Evansville. An appeal is not likely as it is generally believed that Mayor Covert and others prominent in the scheme are heartily glad that the decision has afforded them an excuse to let go of one of the most unique schemes ever devised in this State.

*The Electrical World and Engineer, June 22, 1901.

Theoretical Determination of Power Curves.

We give below several communications having for their subject the article by Mr. W. J. Berry, which appeared in our issue of January 30:

I have before me your number of January 30, containing a paper by Mr. W. J. Berry, on the theoretical determination of power curves. I am much surprised to find that the writer of this paper did not know of any rigid mathematical demonstration of the fact that, with an impressed e.m.f. of sine-wave shape, the resultant power curve is a sine curve of double frequency. I think it might interest him and your readers to know another demonstration, which does not involve any knowledge of calculus.

Let T be the period,

$$f = \frac{1}{T} \text{ be the frequency.}$$

We can represent the e.m.f. by the curve

$$y = A \sin \left(2\pi \frac{x}{T} \right)$$

where x represents the time. The current is represented by

$$y' = A^1 \sin \left[2\pi \frac{x}{T} + \phi \right]$$

where ϕ, which may be positive or negative, represents the difference of phase. Then the power is

$$y'' = y\,y' = A\,A^1 \sin 2\pi \frac{x}{T} \sin \left(2\pi \frac{x}{T} + \phi \right)$$

Now, by using the well-known formula,

$$2 \sin p \sin q = \cos (p - q) - \cos (p + q),$$

we have

$$y'' = \frac{A\,A^1}{2} \cos \phi - \frac{A\,A^1}{2} \cos \left[4\pi \frac{x}{T} + \phi \right]$$

If we transform the equation to a parallel x-axis at the distance

$$K = \frac{A\,A^1}{2} \cos \phi,$$

$$y''' = y'' - K = - \frac{A\,A^1}{2} \cos \left(4\pi \frac{x}{T} + \phi \right)$$

$$= \frac{A\,A^1}{2} \sin \left[4 \frac{\pi x}{T} + \frac{\pi}{2} + \phi \right]$$

or

$$y''' = \frac{A\,A^1}{2} \sin \left[2\pi \frac{x}{\frac{T}{2}} + \frac{\pi}{2} + \phi \right]$$

which shows that the power curve is a sine curve, whose period is $\frac{T}{2}$ and frequency $2f$.—Q.E.D.

It may be noticed that this demonstration saves the consecutive differentiating and integrating of the same function, which process is somewhat new to me. Very truly yours,

MONTREAL, CANADA. V. R. HEFTLER.

In the ELECTRICAL WORLD AND ENGINEER for January 30, Mr. William J. Berry gives an interesting demonstration of the fact that alternating-current power is a simple harmonic quantity of twice the e.m.f. frequency. I give below a somewhat briefer proof of one step in his demonstration which may interest your readers. A somewhat different notation is used:

Let p, e, i be instantaneous and E, I maximum values; ω angular velocity, t time, ϕ a constant angle of phase difference.

Mr. Berry shows that we may write:

$$p = e\,i = E\,I \sin \omega t \sin (\omega t \pm \phi),$$

$$= E\,I\,[\sin^2 \omega t \cos \phi \pm \sin \omega t \cos \omega t \sin \phi],$$

$$= E\,I\,[\sin^2 \omega t \cos \phi \pm \tfrac{1}{2} \sin 2\,\omega t \sin \phi],$$

the second term in the binominal being a simple harmonic of double frequency. I should suggest that instead of the differentiation, integration and substitution for K, the constant of integration, we might treat the first term as follows:

$$\cos^2 \omega t - \sin^2 \omega t = \cos 2\,\omega t$$
$$\cos^2 \omega t + \sin^2 \omega t = 1$$

$$2 \sin^2 \omega t = 1 - \cos 2\,\omega t$$

whence

$$p = \frac{E\,I}{2} \cos \phi - \frac{E\,I}{2} \left[\cos 2\,\omega t \cos \phi \mp \sin 2\,\omega t \sin \phi \right]$$

$$= \frac{E\,I}{2} \cos \phi - \frac{E\,I}{2} \cos\,[2\,\omega t \pm \phi],$$ or if we use $E\,I$ effective,

$$= E\,I \cos \phi - E\,I \cos\,[2\,\omega t \pm \phi],$$ a displaced sine wave

of double frequency, in which the displacement is the average power as the sine wave part $E\,I \cos\,(2\,\omega t \pm \phi)$ averages zero. This gives the significance of K directly as the average power.

SCHENECTADY, N. Y. JOHN C. PARKER.

In the issue of the ELECTRICAL WORLD AND ENGINEER of January 30 I notice an article by William J. Berry on power curves. In it he states that "every alternating-current engineer knows that with an impressed harmonic e.m.f. of sine-wave shape the resultant power curve is a sine curve of double frequency; but so far as the present writer knows there exists no rigid mathematical demonstration of this fact." The matter is so simple that the proof of the proposition is generally not given in full. Every mathematician knows that the product of two sines is another of double the frequency, independent of the phase relation. Following is a solution with notes on this question:

Let e be the instantaneous e.m.f.,
i " " " current,
p " " " power,
E_m " " maximum e.m.f.,
I_m " " " current,
E " " effective e.m.f.,
I " " " current,
P " " average power,
t " " time in seconds,
f " " frequency,
and ϕ " " angle of lag or lead.

We then have

$$p = e\,i = E_m \sin 2\pi\,f\,t \times I_m \sin (2\pi\,f\,t \pm \phi).$$

From formulæ for the value of the sine of the sum or difference of angles,

$$\sin (2\pi\,f\,t \pm \phi) = \sin 2\pi\,f\,t \cos \phi \pm \cos 2\pi\,f\,t \sin \phi,$$

$$\therefore \quad p = E_m\,I_m\,[\sin^2 2\pi\,f\,t \cos \phi \pm \sin 2\pi\,f\,t \cos 2\pi\,f\,t \sin \phi].$$

From formulæ for the functions of double and half arcs,

$$2 \sin^2 2\pi\,f\,t = 1 - \cos 4\pi\,f\,t, \text{ and } 2 \sin 2\pi\,f\,t \cos 2\pi\,f\,t = \sin 4\pi\,f\,t.$$

$$\therefore \quad p = \frac{E_m\,I_m}{2}\,[2 \sin^2 2\pi\,f\,t \cos \phi \pm 2 \sin 2\pi\,f\,t \cos 2\pi\,f\,t \sin \phi],$$

or
$$p = \frac{E_m\,I_m}{2}\,[(1 - \cos 4\pi\,f\,t) \cos \phi \pm \sin 4\pi\,f\,t \sin \phi].$$

$$p = \frac{E_m\ I_m}{2} \cos\phi - \frac{E_m\ I_m}{2} [\cos 4\pi ft \cos\phi \mp \sin 4\pi ft \sin\phi],$$

$$p = \frac{E_m\ I_m}{2} \cos\phi - \frac{E_m\ I_m}{2} \cos (4\pi f t \pm \phi).$$

Now, $\dfrac{E_m\ I_m}{2} = E\,I$ and $P = E\,I \cos\phi$;

$$\therefore \quad p = P - E\,I \cos (4\pi f t \pm \phi) \quad . \quad . \quad . \quad . \quad . \quad \text{Eq. } (a)$$

Equation (a) can, of course, be rewritten.

$$P - p = E\,I \cos (4\pi f t \pm \phi),$$

$$\text{or} \quad P - p = E\,I \sin \left[\frac{\pi}{2} - (4\pi f t \pm \phi)\right]$$

This shows a curve of twice the frequency and symmetrical with respect to an axis, which is a distance P or the average power above the X axis of the e.m.f. and the current.

In Franklin and Williamson's "Alternating Currents," page 60, you will find the remark that

$$p = P - A \cos (2\omega t - \Theta),$$

which is identical with Eq. (a) by changing the symbols; also on page 62, Example 36, this question is given as an example showing that the authors do not consider it as involving any mathematical difficulty.

Steinmetz, on page 364 of his "Alternating-Current Phenomena," shows that

$$p = P\left(1 - \frac{\sin (2\beta - \omega)}{\cos \omega}\right)$$

where $\beta = 2\pi f t$ and $\omega = \phi$ of the above notation. This is also identical with Equation (a).

BURLINGTON, VT. W. H. FREEDMAN.

The following is perhaps a more direct method of developing the power curve than that given by Mr. Berry in your issue of January 30.

Let the equations of instantaneous values of e.m.f. and current be, respectively,

$$e = E \sin a \qquad (1)$$
$$i = I \sin (a \pm \beta) \qquad (2)$$

where E is the maximum value of e.m.f., I the maximum value of current, a the angle of phase and β the angle of lag or lead (phase displacement).

The value of the power in the circuit is, at any instant,

$$w = e\,i = E\,I \sin a \sin (a \pm \beta)$$
$$= W \sin a \sin (a \pm \beta) \qquad (3)$$

Differentiating with respect to a,

$$D_a w = W [\sin a \cos (a \pm \beta) + \cos a \sin (a \pm \beta)]$$
$$= W \sin (2a \pm \beta) \qquad (4)$$

For a maximum, this is

$$W \sin (2a \pm \beta) = 0$$
$$\text{or} \quad \sin (2a \pm \beta) = 0$$

and occurs when $2a \pm \beta = n\pi$, where n is zero or a whole number. Hence, the value of a for a maximum value of ω is

$$a = \frac{n\pi \mp \beta}{2} \qquad (5)$$

and occurs four times, while a varies from 0 to 2π.

Hence, the curve defined by (3) has double the periodicity of either (1) or (2).

From (4), we have

$$w = W \int \sin (2a \pm \beta)\, d\,a$$
$$= -\frac{W}{2} \cos (2a \pm \beta) + C \qquad (6)$$

where C is the constant of integration. Transforming axes so that $w = 0$, $a = 0$, we have

$$C = \frac{W}{2} \cos\beta$$

and from (6)

$$w = -\frac{W}{2} \cos (2a \pm \beta) + \frac{W}{2} \cos\beta$$
$$= \frac{W}{2} [\cos\beta - \cos (2a \pm \beta)] \qquad (7)$$

the equation of the power curve.

Now, substituting in (7) the values of a obtained in (5) we have

$$w_{max} = \frac{W}{2} \{ \cos\beta - \cos [(n\pi \mp \beta) \pm \beta] \} \qquad (8)$$

For $\beta = 0°$ we have

$$w_{max} = W \text{ and } 0 \text{ (two values of each).}$$

For $\beta = 90°$ we have

$$w_{max} = \pm \frac{W}{2} \text{ (two values of each).}$$

That is, when current and e.m.f. are in phase, two values of the maximum vanish, and the two remaining values are both positive and equal to $E\,I$. The power curve then has the same periodicity as the e.m.f. and current curves, with both crests on the same side of the axis of time.

When current and e.m.f. are not in phase, but differ by an angle β, the power curve has double the periodicity of either, with alternate crests on opposite sides of the axis of time. When $\beta = 90°$ the areas of these two crests are equal and the integral of the curve, taken between $n\pi$ and $(n + 1)\pi$ is zero— the condition of a wattless circuit.

NEW YORK. BASSETT JONES, JR.

I was much interested in the article in your issue of January 30 by Mr. William J. Berry, entitled, "The Theoretical Determination of Power Curves," as I had a few days previous to seeing it worked out a proof of the same law with which Mr. Berry deals. I obtain the same final equation, but in a slightly different and, to my mind, in a somewhat better manner, as follows:

I shall use the notation adopted by Mr. Berry and omit the first part of the demonstration as my work is the same as his up to the equation,

$$y'' = a' \sin^2 x \pm \frac{\beta'}{2} \sin 2x$$

From Wentworth's Trig. § 33. $\cos 2x = \cos^2 x - \sin^2 x$.

Substitute for $\cos^2 x$, $1 - \sin^2 x$, and we get $\sin^2 x = \dfrac{1 - \cos 2x}{2}$;

and thus

$$y'' = \frac{a'}{2} - \frac{a'}{2} \cos 2x \pm \frac{\beta'}{2} \sin 2x.$$

Putting for a' and β' their values, $A\,B \cos\phi$ and $A\,B \sin\phi$, respectively,

$$y'' = \frac{A\,B}{2} \cos\phi - \frac{A\,B}{2} (\cos 2x \cos\phi \mp \sin 2x \sin\phi),$$

$$\cos 2x \cos\phi \mp \sin 2x \sin\phi = \cos (2x \pm \phi).$$

Hence,

$$y'' = \frac{A\,B}{2}\cos\phi - \frac{A\,B}{2}\cos\,(2\,x \pm \phi)$$

$$= \frac{A\,B}{2}\cos\phi - \frac{A\,B}{2}\sin\left(\frac{\pi}{2} - 2\,x \pm \phi\right)$$

$\frac{A\,B}{2}$ cos ϕ is the constant of integration K used by Mr. Berry.

The effective values of y and y'' are $y_e = \frac{A}{\sqrt{2}}$ and $y'_e = \frac{B}{\sqrt{2}}$, and their vector product,

$$y_e y'_e \cos\phi = \frac{A\,B}{2}\cos\phi = K.$$

To prove that the axis, X', is the axis of symmetry of the curve $y\,y'$, it is necessary and sufficient to prove that K is the arithmetical mean of $y\,y'$. This mean is given by the area under one cycle of the curve divided by the base, or

$$\text{mean} = \frac{1}{180}\int_0^{180°} (A\,B\,\sin^2 x\cos\phi \pm A\,B\,\sin x\cos x\,\sin\phi)\;d\,x,$$

since while x varies from 0 to 180°, $y\,y'$ goes through a complete cycle, being of double the frequency of the curves y and y',

$$\text{mean} = \frac{A\,B}{180}\left\{\cos\phi\int_0^{180°}\sin^2 x\,d\,x \pm \sin\phi\int_0^{180°}\sin x\cos x\,d\,x\right\}$$

$$= \frac{A\,B}{180}\left[-\frac{1}{2}\cos\phi\,\cos x\sin x + \frac{x}{2}\cos\phi \pm \frac{1}{2}\sin^2 x\right]_0^{180°}$$

When $x = 0$ all terms in brackets become zero, and when $x = 180$ all but the second vanish, giving for the mean,

$$\frac{A\,B}{180} \times \frac{180}{2}\cos\phi = \frac{A\,B}{2}\cos\phi = K.$$

The quantity $\frac{A\,B}{2}\cos\phi$, being the vector product of the effective values of the pressure and current waves, is obviously the power as measured by an ordinary wattmeter.

LOS ANGELES, CAL. FRANK R. STOWE.

The Uses of Natural Gas.

The most profitable customers that the natural gas companies have are the householders. The natural gas companies of to-day supplied 509,695 domestic consumers in 1902. So says Mr. F. H. Oliphant in his report on the "Production of Natural Gas in 1902, which has just been published by the United States Geological Survey as part of its annual volume on Mineral Resources. Natural gas, he states, is used on many other hearths than the purely domestic. Iron mills, steel works, glass works and various other establishments to the total number of 8,103 made use of its energies in 1902. The number of natural gas companies that supplied the 509,695 home bodies and the 8,103 establishments in 1902 was 2,147, which represented a gain of 602 companies over the enrollment of 1901.

One of the most effective uses to which natural gas has been put is as motive power for engines. The natural gas engine came into favor about ten years ago, when its use was first employed in pumping wells. Afterward, in forms of magnitude ranging from 5 to 500 hp, it was extensively introduced into manufacturing plants, where it has successfully demonstrated its economy and reliability. Owing to the large number of points that are often widely separated and are difficult to supply with other fuel, it is particularly applicable to the pumping of oil wells and to driving pipe line pumps.

Serious Subway Fire In New York City.

At ten minutes to nine on Wednesday morning, April 6, a remarkable accident occurred in the excavation for the rapid transit tunnel at the southwest corner of Broadway and Fulton Street, in New York City. To obtain the space necessary for the tunnel, the contractors have been obliged to rearrange all of the underground structures found in the path of their work. The task of doing this is plainly one of the first magnitude and has been rendered enormously difficult on account of the conditions imposed by public opinion, which required that the work should be carried on without interruption of street traffic. As a result of these conditions, the spectacle of gas pipes carried overhead along Broadway, New York, has been one of the many curiosities of the metropolis. Near this point, and in front of St. Paul's Church, is a shaft connecting between the tunnel and a temporary bridge extending across Broadway.

The disturbance which has been caused to the telephone, telegraph and electric light circuits in this subway excavation has been typical of that which has taken place along the entire route of the rapid transit tunnel, already nearing completion from the City Hall northward. From the location in trouble last week and running south to Wall Street, and some distance beyond, as well as running north to the City Hall and the Postal Building, at Murray Street, there extends the most complex and important wire network which exists

FIG. 1.—CABLES AT SCENE OF THE FIRE.

in this or any other country. This, together with the ponderous gas and water mains and sewers, with their various lateral connections, constitutes a plexus of underground conductors unparalleled in their importance and intricacy. In the midst of this system, which is the spinal cord of the city's underground communications, there occurred the accident above referred to. It was simple in its nature and insignificant in the direct damage which it produced. Its indirect consequences were far-reaching and not only produced a paralysis of the local means of communication, but also suspended for the time being important lines of communication to all parts of the United States and Canada.

To make way for the subway structures the contractors had removed the usual protecting manhole provided by the Empire City Subway Company for the conductors running in its ducts and had massed the cable thus exposed in a tangle most inextricable in its nature. To protect these cables from damage by workmen, the contractor had wrapped them with burlap coverings and surrounded them with woodwork. One of the cables which had been damaged was being repaired by a telephone splicer, who, in the carrying out of his work, employed the usual pot of heated paraffine, melted lead and gasoline stove. On account of some circumstance, which will probably never be discovered, the paraffine took fire and flame was immediately communicated to the burlap about the cable and to the woodwork. The heat generated for the time being was intense. The burlap took fire and melted off the lead covering of 22 large telephone cables, containing 5,250 pairs of wire, 8 Western Union cables carrying important telegraphic circuits, 5 Postal Telegraph cables carrying wires of equal importance, a burglar alarm cable of the Holmes Electric Protective Company, a cable of the American District Telegraph Company, a cable of the New York Stock Quotation Company, a cable of the Automatic Fire Alarm Company, a burglar alarm cable of the Mercantile Electric Company, a city fire alarm telegraph cable, a Gold & Stock Ticker cable, several circuits of the police telephone system and some other circuits of a miscellaneous nature.

The effect upon the telephone service was immediate and profound. The short-circuiting of these wires overloaded the ringing generators and storage batteries of the Cortlandt Street central office. This resulted in the operation of the circuit-breakers. By this means not only were the wires in the cables actually injured thrown out of service, but all of the wires centering at Cortlandt Street, coming in through cables from other directions, were rendered inoperative. In addition to this, a mass of trunk wires extending from the Broad,

FIG. 2.—EXCAVATION AT ANN STREET, NEAR SCENE OF FIRE.

John and Cortlandt Street offices and going to points north were made useless.

At nine o'clock on the morning in question the Cortlandt Street office had been put entirely out of business. To do this it took just ten minutes. All of the other offices were intact, but communication between the three offices above mentioned was cut off to all points north and communication between these three offices themselves was also cut off. Included among these injured cables was one of the Pupin cables which had just been laid, to replace the overhead west side line so recently removed. The interruption of this cable cut off long-distance communication with points in the east, including New Haven, New London, Providence, Boston and other New England points. Important Buffalo and other up-State wires were also thrown out of service.

The confusion which this produced in the business community of New York can hardly be described. Mayor McClellan organized a set of special messengers, which he called his "pony express," but notwithstanding this he declared that the business of the city was practically suspended. Large commercial houses, newspaper offices and other large concerns tried in vain to find a substitute for the telephone. Some of them went temporarily out of business.

To meet this emergency the resources of the New York telephone Company were not found wanting. Available for work in this emergency there were the entire staff of the construction department, consisting of 800 men and the staff of the maintenance department, consisting of 1,000 men. This was a case, however, where mere numbers would not count. It was impossible to employ in the very limited area where the damage occurred more than twenty-five men at a time. Five minutes after the accident the machinery of the telephone company was at work to repair the damage. A plan of campaign was determined upon. Relays of picked men were provided, and within an hour and a half after the accident all of the long-distance wires in the Pupin cable were restored to service. By afternoon the damaged local wires began to operate and at nightfall 800 of the damaged trunk lines were in successful operation and 200 of the subscribers' lines were restored. By the morning of Thursday a still further increase in the number of wires was reported and by Thursday night the entire telephone system was again working as though the accident had never occurred.

To those who were permitted to pass the cordon of police, which was thrown about the scene, the results obtained seemed to be nothing short of marvelous. The various telegraph and other companies concerned were also represented in full force, so that by Friday the service of the companies concerned was proceeding normally.

While the occurrence of this accident was the cause of extraordinary inconvenience to the telephone company and to the public, and produced excitement rarely witnessed in down-town New York, it served one good purpose. It called attention to the inestimable value of the telephone service as exemplified in this city and served to bring to public attention in the most sensational manner the utter paralysis of business which would result were the entire telephonic and telegraphic system of this city suspended. Owing to the fact that Manhattan Island is divided into seventeen telephone districts, each with its own fire-proof central office and underground subway connections, a complete interruption of the telephone service could be brought about only by a catacylsm. The results produced by this temporary interruption of even one office has shown the wisdom of the engineering plans, which have provided that all of the eggs should not be placed in one basket, .i e., one big exchange. The conditions which obtained at the corner of Fulton Street and Broadway are by no means unique. They are merely typical of the snarl of telephone cables which has been produced at scores of places throughout Manhattan Island during the construction of the underground road. That the service has not heretofore noticeably suffered from these interruptions can only be interpreted as evidence of the extraordinary care manifested by those charged with the maintenance of the telephone service.

The General Electric-Allgemeine Electricitats Gesellschaft Combination.

A special meeting of the Allgemeine Electricitäts Gesellschaft was held at Berlin February 27, at which was submitted a report of the details of recent arrangements entered into by that company with the General Electric Company and several European electric manufacturing companies.

Referring to the amalgamation of the Allgemeine Electricitäts Gesellschaft with the Union Elektricitäts Gesellschaft, it was stated that the barriers have been removed, and now that the relations to the American company have been adapted to the new condition of affairs "this amalgamation seems to be the last conclusion in the joining of interests which were but a step in this direction." Referring to the journey of Managing Director Mr. Rathenau to the United States, one of the more important reasons is stated to have consisted in the settling of the future relations between the Allgemeine Electricitäts Gesellschaft and the General Electric Company. "The latter company is the most important representative of the electrical industries in that part of the world. The works of this company are of vast dimensions. It controls a large staff of able men from the scientific and practical engineering world; and it furthers with ample means and rare generosity the development of electrical industry both in laboratory and testing shops. A close relation to this firm seemed all the more desirable to the Allgemeine Electricitats Gesellschaft by the alliance of the Union Electricitäts Gesellschaft with the Thomson-Houston Company, which has since been absorbed by the General Electric Company. The General Electric Company has various branch companies in Europe, i. e., England, France and the Mediterranean, which companies have retained the name of Thomson-Houston. In America the General Electric Company controls the Edison General Electric Company, the Thomson-Houston Electric Company, Fort Wayne Electric Works, Stanley Electric Manufacturing Company, Eddy Electric Corporation, General Incandescent Arc Light Company, Sprague Electric Company and the Northern Electric Company.

"The territory of the Union Electricitäts Gesellschaft comprised Germany, Central and Northern Europe and the Balkan States. With the aid of local capital they had founded the Austrian and Russian Union Electricitäts Gesellschaft and the Union Electrique in Brussels. The various companies are confined to their geographical territories by agreements between these companies and the parent company, but they are at liberty to extend their field of operation by a special agreement. In this manner the Union Electricitäts Gesellschaft has, by an arrangement with the Mediterranean Thomson-Houston Company, acquired the right to carry on business in Italy, subject to certain conditions.

"The element which unites all the companies of this vast group is the interchange of patents and experience. Not only did we endeavor to join this concern and establish friendly relations with the European undertakings, but we were anxious to universalize the more important technical and commercial interests, which we possess in our steam turbine patents and those of Riedler-Stumpf. The combination of the latter with those of the Curtis group, which the General Electric Company had acquired for its own exploitation in the United States, and which it was about to utilize in other countries, seemed to us very useful, indeed. Our numerous agreements with the American and European companies contain the following chief points:

"1. An understanding by which the Allgemeine Electricitäts Gesellschaft and the General Electric Company define the territories of their own and their branch companies and each party leaves to the other the rights and experience for each individual territory. The exclusive territory of the General Electric Company comprises the United States of America and Canada, that of the Allgemeine Electricitäts Gesellschaft Germany, including Luxemburg, Austria-Hungary, Russia in Europe and in Asia, Finland, Holland, Belgium, Sweden, Norway, Denmark, Switzerland, Turkey and the Balkan States. With regard to the territories of the various branch companies in Europe, separate agreements have been made. For the other continents, including South America, a joint working of the two large concerns is proposed, an agreement which will no doubt result in a profitable joint undertaking. The present condition of affairs holds good in Spain and also in Greece.

"2. The General Electric Company and the Allgemeine Electricitäts Gesellschaft will form a company with a capital of three million marks for the exploitation of the Riedler-Stumpf and the Curtis steam turbine patents in the territory of the Allgemeine Electricitäts Gesellschaft. In this combination the Curtis patents are valued at 1.8 million marks and the Riedler-Stumpf patents at 1.2 million marks. The Allgemeine Electricitäts Gesellschaft has secured a license to supply all non-European countries with the exception of the United States and Canada. In these latter countries the General Electric Company has secured the Riedler-Stumpf rights.

"3. The rights for the use of the Curtis patents for marine engines had been secured by the International Curtis Marine Turbine Company. This company had given the license to the Allgemeine Electricitäts Gesellschaft for their European territory, while the Allgemeine Electricitäts Gesellschaft allowed the marine turbine company to use the Riedler-Stumpf patents for their marine work.

"4. For the purpose of working the steam turbine patents of Profs. Riedler and Stumpf, the Allgemeine Electricitäts Gesellschaft has formed a 'Company for the Introduction of Inventions, Limited.' The patents have now passed into the possession of the Vereinigte Dampfturbinen Gesellschaft and in the United States in the hands of the General Electric Company, the marine patents having been secured by the marine turbine companies and the inventors, Messrs. Riedler and Stumpf, derive part of the profits from the facilities granted to the Allgemeine Electricitäts Gesellschaft.

"5. A similar contract to that concluded with the General Electric Company has been made with the Thomson-Houston Company for the export trade. Various additional rights have been granted to the British Company, such as a financial participation in the branch companies of the Allgemeine Electricitäts Gesellschaft and of a company which may eventually be formed in Great Britain for the manufacture of Nernst lamps. The Allgemeine Electricitäts Gesellschaft reserves the right to also supply turbines in addition to the other manufactures.

"6. Similar to the relations with the British Company there also exists an exchange of patents and experience with the French Thomson-Houston Company. The Allgemeine Electricitäts Gesellschaft will restrict their French establishment to the sale of their manufactures in France and will supply engines and steam turbines to the French company only. This company has secured the option to draw shares of the Society Francaise d'Electricite Allgemeine Electricitäts Gesellschaft up to a certain amount. On the other hand, the French Thomson-Houston Company guarantees to the Allgemeine Electricitäts Gesellschaft a demand of dynamos in proportion with the turnover of apparatus up to the present time."

The report states that the various agreements give the right to form the following companies:

"1. A company for the manufacture of turbines, turbo-generators and accessory apparatus. The Allgemeine Dampfturbinen Gesellschaft is to be equipped with a share capital of five million marks, to be paid in as required. The shares are subscribed for by the Allgemeine Electricitäts Gesellschaft. For the establishment of a factory it is proposed to use the land, buildings and plant of the Union Electricitäts Gesellschaft, the working of which has been absorbed by the Allgemeine Electricitäts Gesellschaft. The above-mentioned real estate will be let to the Allgemeine Dampfturbinen Gesellschaft for a number of years with the option of their purchasing it outright. The technical management will be in the hands of Director Lasche, who, up to the present, has been looking after the turbine construction work of the Allgemeine Electricitäts Gesellschaft.

"2. The above-mentioned Turbine License Company: This company has already been formed under the name of Vereinigte Dampfturbinen Gesellschaft M. B. H. (United Steam Turbine Company, Limited.)

"3. An Italian company with a capital of six million lire: This will be transferred to the organizations of the Allgemeine Electricitäts Gesellschaft and the Thomson-Houston Company, as well as the Italian turbine patents of the entire group.

"4. An arrangement somewhat similar to that existing between the Allgemeine Electricitäts Gesellschaft and the Union Electricitäts Gesellschaft has been arrived at between the Société Belge d'Electricité Allgemeine Electricitäts Gesellschaft and the Union Electrique in Brussels. A formal amalgamation of these two companies may take place in the future.

"Although the expense in connection with the companies enumerated, the purchase of patents and the sums advanced represent a considerable amount, this is still further increased by the taking over of the shares of the Austrian Union Electricitäts Gesellschaft in which the Berlin Union Electricitäts Gesellschaft is largely interested, and which for this reason and also for the purpose of establishing suitable works in Austria we wish to entirely reorganize.

"Finally the Allgemeine Electricitäts Gesellschaft will probably have to supplement and safeguard the working stock of the Union Electricitäts Gesellschaft, who obtained heretofore the greater part of their working material on a credit system, should they wish to follow the course of action which they have successfully carried out in financial matters during the past twenty years."

After giving details of the plans made for obtaining the necessary capital to carry out the programme detailed above, the report takes up the matter of the arrangements made with the firm of Brown, Boveri & Co. concerning which the following information is given:

"The firm of Brown, Boveri & Co. was formed in 1891 as a limited liability company for the manufacture of electrical apparatus and construction of electric central stations and equipping of railways. In consequence of their large share in the development of the electrical industry and the important contracts, the firm received the municipal power stations, etc., their works had to be enlarged from year to year. The investments in connection with this development led to the transformation of the limited liability company into a joint stock company. Messrs. C. E. L. Brown, W. Boveri, C. Baumann-Stockar and S. W. Brown-Sulzer, of the board of directors, were appointed managers. The works at Baden (Switzerland) employ 2,000 men. In order to increase their output in Germany the firm formed a branch company in Mannheim. The original limited liability company did excellent business from the very first, but their balance sheets have not been published. The balance of the joint stock company show that the decline of business which set in with the new century, while certainly reducing the receipts, has not affected the solid basis of the undertaking. The dividends were 16 per cent., 5 per cent. and 7 per cent., respectively, for the three years, and the dividend for the year ending March 13, 1904, is estimated at 9 per cent.

"The firm of Brown, Boveri have only on rare occasions taken over installations, limiting their field of operation to manufacture. Their foreign organization comprises a branch office in Cologne, Frankfort-on-Main, Metz and Brussels, small branch companies in Paris, Milan and Christiania, representatives in Berlin, Munich, Stuttgardt, Moscow, Madrid, Stockholm, Hartlepool and Melbourne. Practically at the same time as the formation of the joint stock company took place, the firm of Brown, Boveri & Co. took over the manufacture of steam turbines. Agreements with the company for the construction of Brown-Boveri-Parsons steam turbines, in which Messrs. Brown, Boveri & Co. are interested, enabled this firm to build Parsons turbines for Switzerland, Germany, France, Italy, Russia and Belgium. In order to supply turbines for marine purposes, the Turbinia German Parsons Marine Company was formed. With the exception of a few modifications regarding distribution of work and abolition of unnecessary competition, the company will continue to work independently as heretofore and under the same management.

Electric Automobile Delivery Wagons.

During the past week, under the auspices of the Automobile Club of America, as already noted in these pages, trials have been conducted, of the nature of an endurance test, of automobile delivery wagons for freight, express, etc. Seventeen vehicles started and of these fifteen were still "in the ring" when the contest closed on Saturday night. This is regarded as an excellent showing. We illustrate some of the electric types herewith. The data of the test are now being grouped and analyzed, as to the trips made around New York City, under the varying conditions, and the results are awaited with much interest.

In a paper read before the Automobile Club of America as a preliminary to these trials, Mr. Hiram Percy Maxim gave some most interesting data relating to electric automobiles. He considers that the electric automobile has arrived at what would seem to be a fixed and possibly final type. In all but the smaller pleasure vehicles it has two series motors independently connected each to one of the driving wheels. The storage battery is carried below the body between the axles and almost never inside a part of the body. As compared with the steam, gasoline and combination gasoline and electric automobiles, the electric system is practically the only motor system in general use in commercial wagon service. In New York City alone there are now approximately 300 electric wagons and trucks in service.

All wagons of 2,000-pounds capacity, which is the capacity generally used by department stores and for light express service, have to make about 30 miles per day, and the battery equipment of such a wagon should correspond to this service. The price of such a wagon with the usual type of department store body is about $2,500. A good battery will do 95 days work in such a wagon before it needs cleaning, which consists in cutting each connecting strap so that "mud" may be washed from the plates and from the jar. The cells are then reconnected, or "burned" together, and after being given a slow charge are again ready for service. After this cleaning they run about 75 days more before the mud has again accumulated to a point requiring another cleaning. After this second operation it is usually found that the wooden separators, if used, require to be replaced by new ones; this latter requirement involves the separation of plates when they are removed from the jar and means more labor and a greater breakage of separators and plates than at the first cleaning. When this has been done and the battery has gone into service for the third time, it is good for about 60 days more work before all of the active material on the positive plates has been shed and their useful life ended. When this point is reached a new set of positive plates is substituted and since this means the handling of fragile acid-soaked wood separators, these also must be replaced by new ones. The battery then starts out entirely fresh except for the negative plates. In most cases these hold out and show no signs of failure until the next cleaning and they do not appear to give out together as do the positives. An average might be set at one set of negative plates for every 1⅔ sets of positive plates.

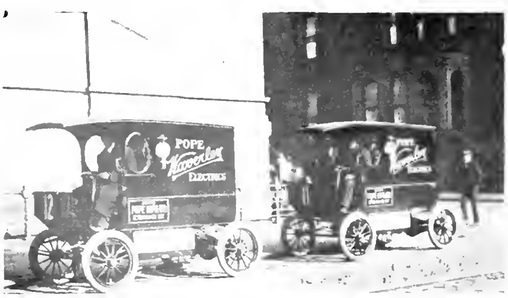

FIG. 1.—ELECTRIC DELIVERY WAGONS.

Taking a full year's work, the cost per annum for a battery under the above conditions is about as follows: New positive plates,

FIG. 2.—ELECTRIC EXPRESS WAGON.

$155; new negative plates, $84; new wooden separators, $26.10; rubber separators, $4.55; rubber jars broken in service and handling, $21.70; total repair in connection with battery, $65; supplies and all other expenses, $43.50. Total, $404.85. On the basis of 30 miles per day and 288 full working days per year for such a wagon, this means 8,640 miles per year, which brings the battery maintenance expense to 4.68 cents per vehicle mile, or $1.40 per day.

As to rubber tires, on a 2,000-pound wagon, a 3½-in. tire is a generous one and the price of a set of such tires, allowing something for scrap, is about $188. In New York City such tires may be depended upon for about 9,000 miles service, which is equivalent to 2.09 cents per vehicle mile, or 62.7 cents per day.

FIG. 3.—ELECTRIC EXPRESS WAGON.

For charging, the requirement is 14.2 kw-hours per day per vehicle. If this is taken from an isolated plant with which a stable or store may be equipped, the cost would never be above 2 cents per kw-hours, and when taken from the street mains it usually amounts to something nearer 4 cents. Assuming 3 cents, on a basis of 288 working days per year, the total consumption is 4,090 kw-hours, which at 3 cents is $122.70 per annum, or 1.42 cents per vehicle mile.

For the cost of general repairs it is stated that the annual charge will be about 4 cents of the price of the wagon, the batteries and tires being left out. In the modern type of wagon costing $2,500, the price less batteries and tires is $1,827; 4 per cent. of this is $73.10 per annum, or 85 cents per vehicle mile as the average for general repairs for this size of wagon. The depreciation may be taken at 10 per cent. on a price of the vehicle less the batteries and tires, which would amount to $182.70, or 2.12 cents per vehicle mile. Taking the interest on the investment at 8 per cent., this would be $125 per annum, or 1.45 cents per vehicle mile.

The various items are, therefore, as follows: Battery maintenance, $404.85; tire maintenance, $180; cost of charging current, $122.70; general repairs, $73.10; depreciation, $182.70; interest on investment, $125. This makes a total per annum of $1,088.35, or 12.61 cents per vehicle mile. This amounts to $3.78 per day, or if 250 packages per day are delivered, to 1.51 cents per package.

The paper next took up the cost of maintaining 3-ton and 5-ton trucks. By the means of an analysis similar to that which precedes, the annual cost of such a truck is found to be $1,609.77, or 23.2 cents per vehicle mile, or 11.6 cents per ton mile, or $5.57 per day. In a similar manner the cost of a 5-ton truck is found to be $1,760.85 per annum, or 30.57 cents per mile, or with the average load, 8.74 cents for every ton hauled a mile, or $6.11 per day.

The paper gives a lengthy discussion of the various items in the above totals. The conclusion is that the direction for the future motor lies in reducing the cost due to the battery, tires and depreciation.

As to the battery factor, it is stated that two new automobile batteries are at present being weighed in the balance, one of these being that of Mr. Edison, and the other a Planté type. The latter is an old battery conventional in form, but owing to its construction its active material sheds less rapidly than in the pasted type, the plates consequently lasting longer. It is stated that this battery has a most creditable record to date.

As to the Edison battery, it is claimed by the manufacturers that the plates never need renewing in the sense in which that term is considered in the paper. The Adams Express Company has for four months been operating with this battery four of its delivery wagons, and at the present time the manufacturers' claims have been equalled. While a much longer experience will be required to determine the value of this battery, it is theoretically directed in the proper line of improvement and, therefore, worthy of most careful consideration. It suffers, however, from its higher cost and the large amount of charging energy which is lost in recharging. The 2,000-pound wagon which now sells for $2,500 would cost $3,005 with this battery, while the saving in weight is only 375 pounds, and the battery requires 60 per cent. more energy than is required in

FIG. 4.—ELECTRIC TRUCK.

charging lead batteries. In the case of the 2,000-pound wagon this means $204 per annum, instead of $122.70 with the lead battery. It would seem fair to expect more repairs with the Edison battery. An analysis of the different items show, however, a net gain per ton mile for the Edison battery amounting to quite a considerable amount, being 13 per cent. in the 2,000-pound wagon, 12 per cent. in the 3-ton wagon, and 12½ per cent. in the 5-ton truck.

The Planté battery above referred to, which is known as the Manchester "box" type, has a strictly Planté positive plate and what is called a "box" negative plate, and is stated to be unquestionably the longest-lived and most rugged storage battery in existence. The cost of maintenance of this battery is discussed and the calculation shows a net gain practically identical with that of the Edison battery. For instance, in the 2,000-pound wagon it will cost for maintenance 10.93 cents per vehicle mile.

The rubber tire is stated to meet every practical requirement of

FIG. 5.—ELECTRIC DELIVERY WAGON.

automobile traction. The iron tire, while by no means impracticable, does not enable a motor vehicle to give its best performance. Experiments with hard wood tires in segmental blocks and with grain end on have been tried with satisfactory results except during the winter season, when they slip on ice and snow, although very much less so than iron tires. They are long-lived, semi-yielding, semi-noiseless, have very good wearing qualities, give good steering way, even taking car tracks at very close angles and are very cheap. Mr. Maxim considers that while not possessing all the necessary qualifications of a truck tire, they may yet be looked to as indicating the direction in which development should proceed.

The paper also contains a discussion of the maintenance charges of a gasoline vehicle. In the case of a vehicle corresponding to the 2,000-pound electric vehicle, the cost is found to be 9.12 cents per vehicle mile, as compared with 12.61 cents for the corresponding electrical vehicle, or with 11 cents if compared with the Edison battery, or with 10.93 cents if compared with the Manchester "box" battery. For a 3-ton vehicle the cost is 16.1 cents per vehicle mile as against 23.26 cents per vehicle mile for the electric vehicle, 20.47 cents for the vehicle equipped with the Edison battery, or 20.36 cents if equipped with the Manchester "box" battery. In the case of the 5-ton vehicle, the figures are 21.8 cents per vehicle mile, as compared with 30.57 cents for the electrical vehicle, 26.75 cents for the same equipped with the Edison battery, or 26.55 cents if equipped with the Manchester "box" battery.

In conclusion Mr. Maxim said that aside from the inherent peculiarities of the gasoline system which prevent it entering the field at present monopolized by the electric system, there would seem to be good reasons for believing that it will be cheaper at least than the best that we have in sight for the electric. It opens up at once the great field of suburban freight transportation which the electric cannot hope to enter, and which is already calling loudly for some kind of a motor vehicle. Mr. Maxim considers that the time has arrived when we may expect to see the gasoline commercial wagon and truck emerge from the gasoline touring car, just as the electric commercial wagon and truck emerged from the electric phaeton and brougham. As to the steam and combination systems, it is difficult to consider them other than as temporary expedients to be used only until the gasoline system takes final hold.

Washington Meeting American Electrochemical Society.

The meeting of the American Electrochemical Society, held on April 7, 8 and 9, in Washington, D. C., was in its social features perhaps the most enjoyable meeting held by the Society. All the papers presented were interesting and some of them were exceptionally so. The attendance, however, which had been expected to reach a very high figure, did not meet expectations, the number of members and guests registered being somewhat below a hundred. This seems to emphasize what has been pointed out before in this journal, that a national engineering society which holds two general meetings a year, holds one too many.

The very great interest shown in the Society was emphasized by the fact that 50 per cent. of the total membership cast votes for new officers. The results of the election were announced in the Saturday meeting, and were as follows: President, Prof. Henry S. Carhart, Ann Arbor, Mich.; vice-presidents, Mr. C. J. Reed, Philadelphia, Pa.; Mr. E. G. Acheson, Niagara Falls, N. Y., and Prof. C. F. Burgess, Madison, Wis.; managers, Dr. W. H. Walker, Boston, Mass.; Mr. C. E. Acker, Niagara Falls, N. Y., and Mr. Edward Weston, Newark, N. J. Mr. P. G. Salom was re-elected treasurer and Mr. S. S. Sadtler was elected secretary. Prof. Burgess was elected both vice-president and manager, and accepted the former office.

From the report of the secretary it appears that 196 new members were elected last year. The total number of members has now passed the 700 mark. From the report of the treasurer, which was read by Mr. Reed, in the absence of Mr. Salom, it appears that the surplus of the Society at present amounts to $1,652.52. In addition the Society holds $250 for the Frenzel prize, which has not yet been competed for.

As already stated, the social features of the meeting were extremely enjoyable, thanks to the excellent programme arranged by the local committee, with Col. Samuel Reber, U.S.A., as chairman and Mr. Clinton Paul Townsend as secretary. First in importance was the cordial reception of the members of the Society by President Roosevelt at the White House on Thursday noon. On the afternoon of the same day a complimentary excursion on a special "Seeing Washington" trolley car to all parts of the city was much enjoyed, since the weather was good and the parks of Washington presented themselves in the glory of spring. On the evening of the same day a "smoker" was greatly enjoyed, while on the evening of Friday a subscription banquet was held at the Shoreham. Dr. Wiley was a most humorous toastmaster, while Dr. J. W. Richards, Prof. H. S. Carhart, Col. Reber, Mr. C. J. Reed and Dr. Needham made speeches.

Prof. H. S. Carhart,
President American Electrochemical Society.

On the afternoon of Friday a visit was made to the Navy Yard, where the visitors were enabled to see a shrinking of the jacket on one of the largest modern guns. The National Bureau of Standards was also open for inspection on Friday and Saturday. On the afternoon of Saturday visits were made by different parties to the Bureau of Chemistry, the Bureau of Engraving and Printing and an excursion, either by trolley or boat, to Mount Vernon.

In the business meeting on Thursday the amendment to the constitution, according to which the president, vice-presidents and managers shall, after the expiration of the full term of office to which they were elected, be ineligible for immediate re-election, was carried unanimously. It was also announced that the board of directors has decided to hold the next meeting during the week of the International Electrical Congress in St. Louis in September.

Following is a report of the papers presented at the meeting and of the discussion which followed the reading of papers:

STANDARD CELLS.

A paper on this subject was read by Dr. F. A. Wolff, of the National Bureau of Standards. In view of the fact that the advisability of an international agreement concerning the fundamental electrical units will be discussed in St. Louis at the International Electrical Congress this autumn, the author gave a review of the main points which are to be taken into consideration in connection with this question. Of the three units—ohm, ampere and volt—only two should be defined; the third one, then, follows from the two others by means of Ohm's law. Of these three units, the ohm is already exceedingly well defined and its definition can be easily made perfect by slight modifications. The ohm should, therefore, surely be chosen as one of the two fundamental units to be defined; the question is thus whether for the second unit the ampere or the volt is to be selected.

The author discussed the comparative advantages and disadvantages of defining either the ampere or the volt. A high accuracy can be obtained in both cases, but if the volt is defined in terms of the e.m.f. of a standard cell, one obtains certain distinct advantages which are not obtained when selecting the ampere as a fundamental unit. As standard cells, both the Clark and cadmium cells show a good constancy and accuracy, but the latter has the enormous practical advantage of a low temperature coefficient. The hysteresis, due to temperature variations in the Clark cell, may cause considerable mistakes in practice which are, of course, absent in the Weston cell. Moreover, the mortality of the Clark cell is quite high on account of its construction, and a layer of gas may be formed and interrupt the circuit. This is not the case in the Weston cell. For these reasons the author is sure that the Weston will replace the Clark cell.

The author then discussed the various methods of the preparation of the materials and described especially a new method of preparing mercurous sulphate in a uniform and well-defined state. It will be remembered that this is most important because the German Reichsanstalt and the British National Laboratory have found that lack of uniformity of the mercurous sulphate was the principal reason in the variation in the results so far obtained with standard cells. Dr. Wolff's method of preparing the mercurous sulphate is an electrolytic one. He uses a mercury anode and a mercury cathode with an electrolyte of sulphuric acid. The grain structure of electrolytic mercurous sulphate is such that there is no probability that it may influence the e.m.f. The author finally thinks that a Weston cadmium cell with saturated solution should be used for establishing the second unit. The unsaturated type of the Weston cell is also very good and its temperature coefficient is absolutely zero. The apparatus for the electrolytic preparation of the mercurous sulphate was exhibited.

PREPARATION OF MATERIALS FOR STANDARD CELLS AND THEIR CONSTRUCTION.

A paper on this subject by Prof. H. S. Carhart and Dr. George A. Hulett was then read by Prof. Carhart. The authors first discussed the preparation of mercury, cadmium sulphate, cadmium amalgam and then dealt at length with the production of mercurous sulphate and it is very interesting to note that the method developed by the authors is in all essential points identical with that worked out independently by Dr. Wolff. Their method for securing Hg_2SO_4 free from nitrate was described as follows:

In a flat-bottomed beaker or deep crystallizing dish is placed mercury a centimeter or so deep. This is covered with dilute sulphuric acid (one to six) to the depth of some 10 cm. A platinum wire, protected except at its end by a glass tube, makes contact with the mercury, which serves as the anode; the cathode is a sheet platinum in the H_2SO_4 solution. A current of about 0.3 amp. is passed from the mercury into the solution; crystalline mercurous sulphate at once begins to separate on the surface of the mercury. A stirrer, consisting of a glass rod bent at right angles at the bottom, must be used to keep the mercury surface exposed. The foot of the stirrer passes close to the mercury and must be driven rapidly by a motor.

About 2.8 grams an hour can be prepared in this way. The sulphate should be protected from the light. By means of a separating funnel the excess of mercury may be readily removed from below, leaving the sulphate with more or less finely divided mercury mixed with it. The authors strongly recommend their method as a standard preparation of mercurous sulphate. It gives a lower e.m.f. with mercury than any preparation obtained from $HgNO_3$ and H_2SO_4

or a sulphate. Samples made at different times and with different materials show an extremely close agreement.

The authors have also built cadmium cells in which their electrolytic mercurous sulphate was used and have obtained excellent results from the same. The construction of the cadmium cells is described as follows: Fig. 1 shows the cell ready to be filled. The tubing is drawn out and contracted at *a* so as to leave the diameter about 6 mm., and with thin walls at this point. Fragments of the cadmium amalgam may be introduced into the clean, dry cell, and may then be melted by dipping the leg of the cell into hot water; or the amalgam may be melted under cadmium sulphate solution, and may then be introduced in liquid form by means of a small tube, slightly contracted at the end, and of a diameter that will allow it to pass freely through the neck, *a*. This tube is used as a pipette, and permits the melted amalgam to be introduced rapidly and without splashing. The mercury, the thin paste and the concentrated cadmium sulphate solution may be introduced in the same manner. An alternative method is to introduce the materials through little funnels made out of small test tubes. The funnels must pass through the neck, *a*, of the cell and must reach well down toward the bottom.

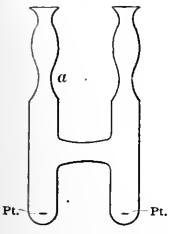

FIG. 1.—DIAGRAM OF CADMIUM CELL.

The electrolytic mercurous sulphate, which has stood with mercury under dilute sulphuric acid, is brought into a Gooch crucible, avoiding free mercury, which interferes with the filtering; it is then washed first with sulphuric acid (made by adding 0.5 c. c. concentrated H_2SO_4, density 1.84, to a liter of water), and then with concentrated cadmium sulphate solution. It is better to reject the top layer, which may be slightly darkened. The paste is next made in a clean agate mortar by grinding together crystals of $CdSO_4$ $8/3H_2O$, and a little mercury, and then mixing in about three volumes of the mercurous sulphate and enough saturated cadmium sulphate solution to make a thin paste. After the mercury and the paste have been introduced into the positive side of the cell, both legs are filled up to the cross tube with the dry, clean crystals of $CdSO_4$ $8/3H_2O$. Enough of the saturated cadmium sulphate solution is finally added to fill the cell to the top of the cross tube.

The sealing off is readily done by means of two small horizontal blast flames, 3 cm. long, directed in a line towards each other and just meeting. The narrow part, *a*, of the cell is brought between the impinging flames, the glass quickly softens, and the top part is drawn off. There is no noticeable heating of the contents of the cell, but it may be advisable before one has acquired the proper skill, to protect the cell by an asbestos disc fitted to the tube below the point, *a*.

One of the special features of these new types of cells is that they do not require any ageing process to reach their equilibrium in e.m.f. The cells reach their equilibrium immediately. This fact, together with the lower value of the e.m.f., compared with that of cells made by the use of mercurous sulphate prepared in any other way, points to the purity of the electrolytic salt, compared especially with that made from the nitrate of mercury.

In the discussion Mr. H. N. Potter urged that the glass from which the containing vessel is to be made should be exactly defined. Glass has, in general, no well-defined composition. Since now pure silicon can be produced cheaply (by the electric furnace process of Tone) we could use it. Dr. Wolff then stated that he had not yet set up cells with the electrolytic sulphurous sulphate, but from its crystalline character and purity he considered it specially suitable for standard cells. Prof. Carhart recommended that if the cadmium cell is adopted as a standard of e.m.f., we should distinguish between the "Weston cell, primary standard" (with saturated solution) from the unsaturated type, which we should call the "Weston cell, secondary standard." Mr. Carl Hering asked whether there was not an uncertainty introduced by hermetically sealing the cell. Prof. Carhart replied that the uniformity of the figures obtained in the tests was so excellent that the hermetical sealing process, which is done at about 20° C., apparently does not introduce any disturbing effect.

SINGLE POTENTIALS OF HALOGEN ELEMENTS.

A paper on this subject was then read by Mr. William Roy Mott. He began with an attack on the ionization theory and considered the solution tensions, assigned to metals by this theory, as impossible. He gives the following single potentials for dilute aqueous solutions: Chlorine, -2 volts; iodine, -0.87 volt; bromine, -1.53 volts; fluorine, -2.53 volts. In a table he gave the voltages of decomposition of various chlorides, fluorides, bromides and iodides in such a form that the well-known additive law is clearly exhibited. This became still more evident by plotting the results in form of a diagram in which equal increments mark the displacement of one metal by another metal or of one halogen element by another halogen element; this results in two sets of parallel lines. This diagram can be used in the calculation of any one of the three factors—the total decomposition voltage, the single potential of the anion and the single potential of the cation, when the other two factors are known. The additive law holds much better for dilute aqueous solutions than for solid salts. Solid salts may, in different forms, possess very different amounts of energy; for example, amorphous silver iodide has a heat of formation of 8.6 large calories, while the crystalline variety has a heat of formation of 14.2 large calories. This introduces a difference of 0.33 volt in their respective decomposition voltages. The author finally expresses the opinion that his results add force to the law that solubility is largely determined by the mutual affinity of the solvent and solute as represented by the heat of solution.

In the discussion which followed Dr. R. Gahl defended briefly the dissociation theory against the attacks of the author and claimed that the author's calculations of the absolute values of single potentials was in disagreement with the principles of thermodynamics.

THE CONTINUOUS ADVANCE OF ELECTROCHEMISTRY.

Dr. J. W. Richards' presidential address, which was delivered at a special meeting on Thursday night, dealt with the above subject, which was discussed under three headings. The author first dealt with the investigation and classification of electrochemical phenomena. He showed what an enormous work has been done in the past in the field of electrochemistry, but thinks that, in spite of the important results obained, even more could have been accomplished by true co-ordination and co-operation. National societies, like the American Electrochemical Society, are operative in bringing workers in different fields together. The author gave a list of such subjects which need further investigation.

The second point discussed by Dr. Richards was the building of a comprehensive electrochemical theory. He thinks that we are now passing through a transition state. He expresses as his own conception of the state of solution that the solute is in an abnormal physical state having resemblance to the gaseous state, and that in some cases a definite compound of the solvent and the solute exists in the solution, it also being in an abnormal physical state, but not abnormal chemically. From J. J. Thomson's recent theoretical investigations of the structure of the atom as a compound of electrons, we might conclude that the dissociation theory will be replaced by the electronic theory.

The third part of his paper dealt with the application of electrochemistry to industrial needs. The author gave a review of what has already been accomplished and spoke at some length on the recent process of Tone for producing silicon in the electric furnace. In concluding he said: If in the battle of industrial competition you are summoned by the conservatives of the industry to strike your colors, answer with the courage and determination of the intrepid Capt. John Paul Jones: "Surrender, sir? We have only begun to fight."

THE COMPOSITION AND RESOLUTION OF VOLTAGES.

The first paper read at Friday's session was by Dr. J. W. Richards on the above subject. It was essentially an enlargement of a former paper presented by the author to the Philadelphia Section of the Society and abstracted in these columns in the issue of February 13, 1904, page 323. The author now gave various numerical examples. For the composition of voltages at the anode, he gave the calculations for the solution of impure copper as it takes place in copper refining, and the solution of a copper-nickel alloy which is one of the steps of the Browne process. As examples of the resolution of voltages at the cathode he discussed the decomposition of a copper-silver alloy on the cathode and the deposition of a metal on the cathode with simultaneous liberation of hydrogen.

In the discussion which followed, Mr. Mott thought that various points might change this method of calculation; for instance, the heat of alloying is not taken into account, nor the overvoltage, etc. Mr. Hering thought that Dr. Richards' calculation is based too much on theoretical considerations, and Dr. Gahl thought that a method of calculation on the basis of the ionization theory would give different results. On the other hand, Mr. Lawrence Addicks and Mr. C. J. Reed stated that the results of Dr. Richards' calculations were in agreement with those actually observed in practice and Dr. Richards also stated that measurements made by him had been found in agreement with his theory.

MOLECULAR CONDUCTIVITY.

A paper on this subject was presented by Mr. C. J. Reed, who pointed out that electrical conductivity is a property of matter, which can be measured only by employing a unit in which there is a definite section, across which the flux is measured, and a definite length in the direction of the flux. Mr. Reed claimed that this is not sufficiently taken into consideration by electrochemists. He compared the ordinary method of electrochemists for measuring molecular conductivities with the case that somebody might measure the conductance of a certain cube of silver between opposite faces, then fuse the silver with n times its volume of lead and measure the conductance of the resulting alloy between faces having n times the area of the original faces, and would then conclude from this that the conductance so measured represents the molecular conductivities of the silver in the two conditions of concentrations. It is wrong to assume that in an aqueous solution of a salt only the salt is a conductor for the electric current. The author claimed that there exists a certain confusion in books and papers on the dissociation theory, due to a lack of distinction between conductivity and molecular conductivity. He concludes that the term molecular conductivity and all theoretical deductions based on investigations of molecular conductivities of different degrees of dilution have no physical significance.

In the discussion which followed, Dr. E. F. Roeber endeavored to show at some length that the term molecular conductivity follows as a consequence from the ionic hypothesis of the electrolytic conductivity of dilute aqueous solutions, and that there is no confusion whatever on this point in the electrolytic dissociation theory. Messrs. Hering, Gahl, Richards and Reber also participated in the discussion. Mr. Reed claimed that Roeber's definition of molecular conductivity is different from that ordinarily used in text-books.

ECONOMIC BALANCE IN AN ELECTROLYTIC COPPER REFINERY.

A paper on this subject was read by Mr. Lawrence Addicks, of the Raritan Copper Works. The author pointed out the close independence of the relations between various factors which form the economic balance in an electrolytic copper refinery. He separated the problem into three variables—tank resistance, age of electrodes and current density. Tank resistance is made up of metallic conductors, contacts, anode slimes, counter e.m.f. due to concentration changes, electrolyte, and a negative quantity due to imperfect efficiency. He discussed these various factors in detail. Concerning the temperature coefficient, he remarked that it is large, and that it is necessary to strike a balance between power saving, cost of heating, increased contact losses and increased cost of keeping the copper contents of the electrolyte down to the required figure. Concerning the question of age of electrodes, much depends upon whether or not the refiner is charged with interest on the metals tied up in the process. Finally, from the standpoint of current density the problem becomes largely one of output. In the light of this multiplicity of relations, it is easy to see why no two refineries use just the same current densities, temperatures, etc. A difference in the cost of labor or power or supplies would tip the economic balance to a new reading at once. Finally, the lowest cost per ton may not be the cheapest cost per ton. This apparent paradox is due to the fact that with a current density somewhat greater than that giving the lowest cost per ton, the output may be sufficiently increased to give greater earnings in spite of the higher cost per unit.

In a communicated discussion, Prof. Bancroft claimed that Mr. Addicks had not given an adequate discussion of the conditions as they exist. Mr. Addicks replied to this criticism and remarked that the final economic balance is the summation of a large number of balances.

HEAT OF NEUTRALIZATION

The next paper read was that of Mr. G. M. Westman on the theory of the heat of neutralization given by Dr. J. W. Richards to the Society last year. The author offers various theoretical objections to Richards' theory and also objects to the assumption that ionization is in no sense to be regarded as a re-solution or a decomposition of the molecules of the constituents. When more water is added to the solution, the molecules expand further and their constituents are further removed from each other. In the discussion which followed, Prof. Carhart remarked that the author's considerations were entirely hypothetical and Dr. Richards stated that the last statement of the author is in agreement with his own view that the dissolved state is similar to the gaseous state.

THE ENERGY OF IONS.

Dr. L. A. Parsons' (University of Utah) paper on this subject was then presented and, in the absence of the author, was read by Mr. S. S. Sadtler. The author discussed at length the objections which had formerly been raised by Mr. Reed against the dissociation theory from the standpoint of the principle of the conservation of energy. He endeavored to show that the views of the dissociation theory are fully in agreement with the energy principle. He also developed some conclusions from the electronic theory of ions.

In the discussion which followed, Mr. Reed thought that the theory developed was that of Dr. Parsons and not the dissociation theory; he also repeated some of his former arguments. The discussion was also participated in by Messrs. Cabot, Richards and Roeber, who defended the dissociation theory, and Gahl, who thought that some apparent difficulties would disappear if one would consider the ionic theory in the light of the electron theory.

ELECTROLYTIC CONDENSER.

A paper by Mr. C. I. Zimmerman was then read in the absence of the author by Mr. A. B. Marvin. The well-known property of the aluminum electrode of permitting the current to pass only in one direction, but not in the other, has already been made use of to construct an electrolytic rectifier, which consists essentially of a combination of an aluminum electrode with an iron electrode. The author has now made use of the same property for devising an electrolytic condenser, which is essentially a combination of two aluminum electrodes. Such an electrolytic condenser is cheaper than other condensers. It shows some leakage, but may be operated continually with an efficiency of 95 per cent. at 110 volts.

Saturday's session was opened with a discussion of Mr. Zimmerman's paper. Mr. Mott gave some additional data on the formation of an oxide film on aluminum. Mr. E. E. F. Creighton remarked that the dielectric strength of the oxide film is so enormously greater than other solid dielectrics that one might suppose the existence of gases in the film. Dr. Karl Guthe confirmed this view and stated that he had found experimentally that gas is contained in the film. Mr. Mott stated that the leakage current is not very large at low voltages in certain electrolytes, like phosphate, etc., but if one approaches the critical voltage, the leakage current becomes large. He has found the dielectric constant of the oxide film to be about 10. Dr. Gahl remarked that in experiments with aluminum electrolytic condensers he had been unable to get constant results.

A STUDY OF THE ELECTRIC ARC.

A paper on this subject was presented by Dr. William S. Weedon, of the General Electric Company. The author gave a great many highly interesting details, but stated frankly that it is still too early to give a complete theory of the electric arc. He only used direct-current arcs. Details were given on the copper arc in air, the copper arc in hydrogen, the iron arc in hydrogen and the carbon arc in hydrogen. It seems that oxidation or combination with the surrounding gas, is not absolutely necessary for the production of a luminous arc, but such a combination facilitates its formation. With regard to the amount of material fed to the arc, there is apparently the tendency for the arc to ionize the surrounding atmosphere if there is not enough material vaporized from the electrode. If much heat is developed, more is vaporized than is employed in transporting the current. Between these two extremes both the atmosphere and the electrode vapor are ionized.

There is a slow gradation from the spark discharges to the true arc, passing through the intermediate stage where both kinds of discharge are present. The main distinction, therefore, between the arc and the spark discharge is that in the former vaporized material from the electrode or electrodes undergoes most of the ionization which takes place, while in the latter the surrounding atmosphere suffers most of the ionization.

The structure of metallic arcs in air are in general as follows: The middle path is not luminous, but the light is derived from the outer mantle and most frequently from that portion of the outer mantle next the inner path. In the carbon arc the outer mantle is not well defined, owing to the fact that the product of combustion is gaseous. It seems probable that the inner non-luminous path is in a way comparable to the Crookes dark space.

From a number of experiments on metallic arcs it seemed probable that the cathode determines the character of the arc, but there are other facts which distinctly contradict such a general statement. The author gave some hypothetical conceptions on the electronic theory of the phenomena in the arc. The paper was discussed by Messrs. Creighton, Browne, Hering and Richards.

COPPER VOLTAMETER.

Some phenomena observed in connection with the use of a copper voltameter were described in a paper of Dr. Isaac Adams and Mr. Barry MacNutt. The paper was read by Mr. MacNutt. The authors had made a determination of the intensity of the horizontal component of the earth field by means of the tangent galvanometer in connection with a copper voltameter. The main points observed were peculiar irregularities in the current when the reversals took place through the galvanometer, and the authors conclude that the reversals should not be made too often, not oftener than, say, every five minutes. Allowance must also be made for the re-solution for the deposited copper. If these precautions are taken, the copper voltameter is suitable for such measurements. In the discussion Mr. Carl Hering remarked that in measurements requiring such an accuracy, the copper voltameter should not be used at all. Mr. MacNutt replied that the consistent results obtained show that the copper voltameter is reliable if only the proper precautions are taken.

ELECTROLYTIC IRON.

A very interesting paper by Prof. C. F. Burgess and Mr. Carl Hambüchen was then read by Prof. Richards. The object of their investigation was to produce, if possible, pure iron in such quantities and at such cost as to make it a valuable material for further inquiry into its properties. They used an electrolyte consisting of ferrous and ammonium sulphates. The current density at the cathode was 5 to 10 amp. per sq. ft. of cathode surface and at the anode slightly less. The e.m.f. for each cell was slightly under one volt, the temperature of the electrolyte being about 30° C. The anodes consisted of ordinary grades of wrought iron and steel, while the starting sheets for the cathodes were of thin sheet iron previously cleaned of rust.

The current efficiency of decomposition was very closely 100 per cent.; that is, there is a deposition of about 1 gram per amp.-hour. The e.m.f. being 1 volt, gives about 2.2 pounds of iron per kw-hour. Although their work was directed toward the production of electrolytic iron in a tense and massive condition rather than in a high degree of purity, analyses which were made showed the purity to be in excess of 99.9 per cent. Not a trace of carbon was detected, and silicon and manganese and other impurities commonly found in iron appeared to be absent. The only impurity which was detected was hydrogen, which was present in appreciable quantities in the metal as taken from the electrolytic tanks. Hydrogen can be driven off, however, almost completely, if not entirely, by heating to a white heat, the evolution commencing at a temperature below 100° C. and becoming rapid at a temperature below a red heat.

The metal containing the hydrogen is so hard that it can be filed or sawed only with difficulty and it is so brittle that it is readily shattered by a sharp blow from a hammer. After the expulsion of the gas it becomes softer and after having been raised to a welding temperature it assumes properties of malleability and toughness similar to those of Swedish iron. The coefficient of hysteresis, the permeability and the electric resistance of electrolytic iron are greatly influenced by the amount of hydrogen in it.

Such electrolytic iron should be useful as a basis for investigating the properties of iron and its alloys. Electrolytic iron also naturally offers a means of manufacturing chemically pure iron compounds and for standardizing solutions in the analytical laboratory. Unless the difficulties encountered in the working of electrolytic iron on account of its roughness offer too serious an objection, it should compete favorably with the purer grades of commercial iron, which are used for various purposes, and which sell for 3 cents and upwards per pound.

In the discussion Mr. Woolsey McA. Johnson remarked that he had made similar experiments, using an electrolyte of ferrous sulphate with an addition of organic acid. He also suggested a furnace for melting pure iron. Mr. Carl Hering remarked that there seems to be but little hope to reduce iron by electrolysis from the ores for two reasons; first, on account of the large area of the tanks required for deposition and secondly, on account of the large energy required. He asked why in the Burgess-Hambüchen process wrought iron or steel is used for the anodes. Cast iron would be much cheaper. Messrs. Johnson and Richards explained that the reason was probably that anodes of cast iron disintegrate too rapidly and the amount of anode scrap is then excessive.

THE REDUCTION TEMPERATURE OF ZINC OXIDE.

A paper was then presented by Mr. Woolsey McA. Johnson, of the Lanyon Zinc Company, on thermo-electric determinations of the reduction temperature of zinc oxide. The author described the furnace used for this purpose and pointed out that Acheson graphite can be so easily machined that it can be used for furnaces or apparatus of almost any form. The methods of the determinations were described in detail. Some of the results are given in the following table:

Material to be Reduced.	Reducing Material.	Corrected Mean of Means.
C. P. Zinc Oxide	1100° Charcoal	1022° C.
C. P. Zinc Oxide Calcined at 1300° C.	1100° Charcoal	1025
C. P. Zinc Oxide	Soft Coke	1029
C. P. Zinc Oxide Calcined at 1300° C.	Soft Coke	1061
C. P. Zinc Oxide	Graphite Turning	1084
Roasted Colorado Ore	Soft Coke	1029
Roasted Joplin Ore	Soft Coke	1073
Roasted Joplin Ore	1100° Charcoal	1059

The results bring out quite clearly what has been the somewhat indefinite opinion of zinc smelters from practical observation, namely, that the temperature of roasting effects the ease of reduction and that different reducing materials have different rates of reduction. He also proposed the hypothesis that the reduction of zinc oxide is caused by the very slight vapor pressure of solid carbon and the slight dissociation pressure of zinc oxide tending to break up the zinc oxide into zinc and free oxygen.

Mr. S. S. Sadtler then showed some samples of porous diaphragms which may be ground down to any convenient thickness, so that their resistance is very small. Mr. C. J. Reed read a letter from Prof. Bancroft in which he called the attention of the Society to the "relative decimal card index for electrochemical interests," suggested by Mr. L. Voege in Zurich, Switzerland. The members of the Society were asked for co-operation. A paper by Mr. Voege on this subject had been sent, but was not read at the meeting. It will be published in the *Transactions* of the Society.

The following three papers were not read or discussed at the meeting, but advance sheets were distributed:

DISSOCIATION BY MEANS OF ALTERNATING CURRENT.

A note by Mr. William H. Davis referring to some experiments made for the purpose of perfecting a method of recovery of cyanogen from the double salts of a cyanide solution. The author describes an experiment in which he found that with the use of a porous cup, rendered semi-permeable with copper—ferro-cyanide, "an alternating current would raise the estimated pressure of a solution concentrated so that complete dissociation was not present."

ELECTROLYTIC PREPARATION OF WHITE LEAD.

In a paper by Mr. C. F. Carrier, Jr., some observations are recorded on the preparation of electrolytic white lead. The author investigated whether basic lead carbonate of the desired composition can be produced by some process differing essentially from that of Luckow, and the process of Richards and Roepper was chosen as the subject of the experiments. It consists in electrolyzing a 5 per cent. solution of a mixture of 1 part Na_2SO_3 and 40 parts CH_3COONa with lead anodes, a small quantity of some nitrate being added to aid the solution of the anode. With a current density of 100 to 200 amp. per m^2, the acetic acid anions are supposed to be decomposed at the anode, yielding CO_2 to precipitate the white lead, the necessary admixture of hydroxide being formed by action of the sulphite.

The author found that the use of copper cathodes reduces the voltage between the cell terminals. With a current density of 100 amp. or more per m^2, the anode dissolves irregularly, "pitting" badly. With a solution containing enough hydroxide to precipitate white lead, spongy lead is deposited on the cathode. To prevent a large deposit of lead on the cathode, it would seem necessary to have a permanent store of CO_3 ions in the solution, thus making Na_2CO_3 or other soluble carbonate an essential constituent of the electrolyte. The solution effect of nitrates on lead, when added to the acetate solution, seems to have a higher efficiency than chlorates alone. The tendency of lead to deposit on the cathode is less with the more dilute solution.

FERRO-NICKEL FROM PYRRHOTITE.

A paper by Mr. E. A. Sjöstedt gives an account of electric smelting experiments made at Sault Ste. Marie for the manufacture of ferro-nickel from pyrrhotite. The problem presented for solution consisted in the utilization to the best advantage of the nickeliferous pyrrhotite of the Sudbury district, with special reference to the saving of the sulphur and iron, as well as of nickel and copper contained in the ore. It was decided to hand-sort the ore at the rock house using the grade higher in copper and gangue for the ordinary matte smelting, and the grade low in copper and gangue, but high in sulphur and nickel for the ferro-nickel industry. Since this latter ore with its high sulphur content requires a large excess of basic admixture which, however, results in a slag too refractory to be kept fluid by the blast furnace heat, it was decided to try an electric furnace process.

He describes various preliminary experiments. The final furnace used is shown in Fig. 2, and contains a rectangular water-jacketed

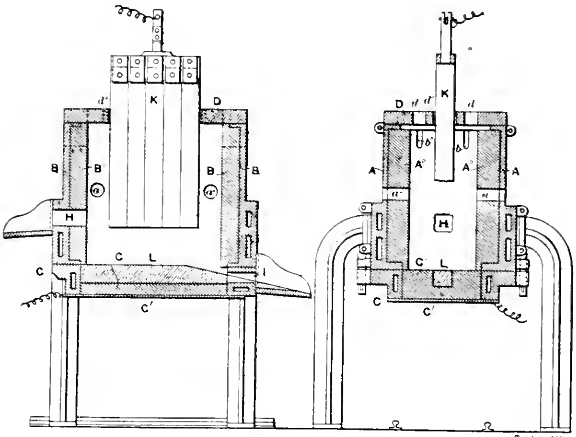

FIG. 2.—SJÖSTEDT FURNACE.

body case, $A B$, with refractory lining, A^0B^0, provided with a slag notch, H, vent holes, a^0, and stroke holes, b^0, a water-jacketed bottom frame, C, held removably on that body, and provided with a refractory lining on a plate, C^1, screwed to that frame, and having a tapping hole, I, provided in one of the ends; a cover of refractory material, D, having feed and vent holes, d and d^1, and opening for the electrode; an upper electrode, K, and a bottom electrode, L, embedded in the bottom lining, C^0, and its ends in contact with the metallic frame of the bottom.

In this furnace ferro-nickel was made for several days from poorly-roasted ore (with about 3 per cent. sulphur and about 53 per cent. iron) at the rate of 60 pounds per hour with an electric energy of 108 kw. With a furnace of 300 or 500 hp, which would be more economical, 200 hp would probably suffice for obtaining a gross ton of ferro-nickel per 24 hours. He gives an estimate of the cost from which he concludes that a profit of over $5 per ton metal produced could be obtained. The process has, however, not yet been established on a commercial scale.

Technical Education.

In a very interesting address recently delivered before the Thomas C. Clarkson Memorial School of Technology on Founder's Day, Dr. F. A. C. Perrine took as his subject, "The Success of the Educated Man," which he treated largely with reference to success in science and engineering. Referring to the importance of fundamental knowledge, he said: "The student often chafes at the beginning of engineering and professional training at the apparent remoteness of the technical knowledge itself. He wonders at the very deep foundation being laid before he begins the study of its applications. If he be a true student and is to become a successful man, it is this foundation which in future will remain and form the basis of his power, remaining even after the whole superstructure has been swept away. Conditions change and methods change, and only scientific fundamentals remain. The arts of to-day have been rapidly changing arts, and indeed the knowledge of to-day is often, we may almost say always the ignorance of to-morrow. Power only comes to him who can build continuously while sweeping aside from his foundations the structures so fondly thought stable; and beginning anew, mount each time higher and higher with a more and more stable superstructure."

Magnet Steel.

During the past several years considerable work has been done abroad on the subject of producing a magnetic material for electrical purposes uniting the properties of high permeability and low hysteresis. One of the most promising outcomes is a magnetic material patented several months ago by Robert A. Hadfield, of Sheffield, England. From the patent specifications, the following is abstracted. An important feature of the process is the heat treatment described:

The object of the invention as stated is to produce an improved material having specially high permeability and electrical resistance and low hysteresis qualities. These qualities can be produced by alloying iron with other elements, among which are silicon and aluminum, phosphorus also yielding satisfactory results, as well as combinations of two or three of these elements.

Pure Swedish or other suitable pure iron is melted in a common crucible or electrically along with silicon or aluminum or phosphorus, employing a percentage of these additions varying from one-quarter of one per cent. to 5 per cent. Only one of the three elements mentioned or two of them, or all three may be employed. Instead of the crucible process the decarbonized or desiliconized iron produced by any steel-making process—such as the open-hearth, the pneumatic or the electrical process—may be used, adding to such iron the desired percentage of silicon, aluminum or phosphorus. The molten alloy is then poured into suitable ingots.

As an example of the exact composition of the alloy produced, one actually manufactured contains 2.75 per cent. silicon, .07 per cent. carbon, .08 per cent. manganese, .03 per cent. sulphur, .03 per cent. phosphorus.

The material produced as above described is valuable on account of its high magnetic permeability, its high electrical resistance, and low hysteresis for efficient use in transformers and other electrical apparatus in which these qualities are useful.

The superior qualities of improved alloy can be still further enhanced by a treatment involving alternate heating and cooling and generally carried out as follows: The material is first heated to between about 900° and 1,100° C. and allowed to cool, preferably quickly. Then it is reheated to between about 700° and 850° C.—that is, to a temperature lower than the one attained during the first heating—and then allowed to cool very slowly. In practice the cooling has been often extended to last several days. Either one or both of these treatments may be frequently repeated, or after the first treatment has been carried out the second type of heating may be frequently repeated. A steel alloy of the composition above mentioned may be taken, heated to 1,070° C., cooled quickly to atmospheric temperature, reheated to 750° C., cooled slowly, again reheated to 800° C., and again cooled slowly. When the best results are desired it is of great importance to use the exact temperatures that correspond to these results, and careful pyrometer readings should be taken for this purpose. It is important to keep the percentage of elements, such as carbon and manganese, which are not used for the purpose of the invention, as low as possible—say carbon under about .12 per cent. and manganese under about .12 per cent.

It will be seen that a certain proportion of pure iron is replaced with a body such as silicon, aluminum or phosphorus, which are materials of low magnetic properties or so-called "non-magnetic" materials. This addition has a very remarkable effect on the magnetic permeability, the electrical resistance, and the hysteresis quality of the alloy produced. In fact, the improved alloy has a higher magnetic permeability and a lower hysteretic constant than any magnetic body of which there are data, including the purest iron. This remarkable result may be due to the strong chemical affinities of the aluminum, silicon, on phosphorus for oxygen and the halogens.

Aluminum and phorphorus and their combinations with each other or with silicon are to be considered equivalents of silicon for the purposes of the invention, as well as any other element or combination of elements which will produce the same result—to wit, a greater magnetic permeability, a higher electrical resistance, and a lower hysteresis quality than is exhibited by the purest commercial iron obtainable.

New Telephone Patents.

MESSAGE-COUNTING DEVICES.

The establishment of the message rate system of telephone charges upon so sound a basis that it completely overshadows its predecessor, the flat rate system, brings almost every exchange manager face to face with the knotty problem of recording individual calls. For years the operators have been burdened with the responsibility and labor of writing charge checks, and although the very appreciable drag upon the service rendered necessary the employment of more operators than previously to handle a given amount of business, the extra expense of these was more than compensated by the savings in other directions. With the recent rapid growth in the telephone subscriber list, and the accompanying and necessary tendency toward larger and larger switchboards, the annual charges on switchboard for each extra operator bid fair to counteract the advantages of message charging. In the endeavor to meet the emergency all sorts of message-counting devices have been produced, ranging from a completely automatic and unsuccessful meter at the central office, to slot machines on the subscriber's premises. Many of these devices have the defect that unscrupulous users may "beat" them.

Recently there have appeared patents for three devices designed to avoid this possibility by so arranging the apparatus than conversation with a desired party can only be carried on after a toll has been registered. In all three of these devices the counting mechanism is at the premises of the subscriber and all tolls are registered manually by him.

The first of these systems has been invented by J. H. Meyer, of Magdeburg, Germany. Herein there is located at the subscriber's station in addition to the usual apparatus, a push-actuated counter and an associated instruction target. At the central office the pairs of connecting cords have a switching key and two listening keys. Of these latter one gives connection toward the calling subscriber only, while the other is used in connection with the called subscriber only. The operation of the system may be described in general terms as follows: Upon the central office operator receiving a calling signal and making response with the proper answering cord and associated answering listening key, and the desired number is ascertained, she completes the connection to the called subscriber. For communicating with him the calling listening key must be used. When the operator desires the calling party to converse with the called one, she manipulates her switching key. This latter performs several functions, but most important for our present purposes is that of energizing a relay in the cord circuit, to open one of its lines and thereby separates the calling and called lines, and the sending of a current impulse to the calling station to display the instruction target through the agency of an electromagnet, the target bearing a legend, "Please press the button and then call." When the button is pushed the count is registered, the target obscured and the cord circuit by the release of the cord circuit relay automatically completed, thus permitting through conversation.

A second of these systems is described in a patent granted to F. R. McBerty, of Evanston, Ill., and assigned to the Western Electric Company. In this system the answering response of the operator causes a current to flow through a polarized magnet at the subscriber's station in a manner to release a latch controlled by its armature. This results in a half count upon a register associated with the subscriber's instrument. Upon the response of the called subscriber, the operation of cord circuit relays controlled thereby, reverse the circuits toward the called subscriber and cause through the agency of his polarized relay a short-circuiting of his transmitter. He can, therefore, hear the responding voice of the called party, but cannot converse with him until he has removed the short-circuit about his transmitter by pushing his counter button and charging up a call on his register.

The third system upon these same lines is the combined work of F. R. McBerty and of Charles E. Scribner, of Chicago. The patent for this system is also assigned to the Western Electric Company. In this system a short-circuiting of the transmitter is caused by the first response of the operator, it being necessary for the subscriber to press his counting button upon the request of the operator, before he can give the desired line number to her for connection.

TELEPHONE CABINET.

Under the above title there has been patented by W. B. Atlick, of Lancaster, Pa., a telephone enclosing booth designed to shield the user from extraneous noises. This booth comprises a stationary floor, roof and side pieces, the whole adapted to be closed by a folding curtain which registers at its top and bottom with floor on roof rails. A horizontal cross-section has the shape of the letter D, the rounded portion being the closed curtain. When open the curtain, made of vertical strips hinged together bellows fashion, passes into a small space behind one of the side boards. Glazed lights, in either side board and a roof window admit the necessary light.

IMPROVED POLARIZED RINGER.

Every telephone man is familiar with the polarized bell to the extent of a recognition of the necessity for adjustment of the relative positions of the armature and magnet poles, and everyone who has attempted to regulate this adjustment must have been impressed by the awkwardness of that arrangement most common, namely, that in which a brass yoke carrying the armature trunions, is driven and clamped upon threaded frame posts by means of two nuts. Mr. W. W. Dean, of Chicago, has invented a bell in which other means for accomplishing this adjustment is provided. This is shown in Fig. 1, which is a sectional view of the armature end of the magnets.

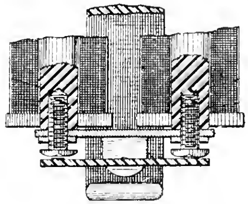

FIG. 1.—DEAN BELL.

As may be seen, extension poles in the shape of bolts with hexagonal heads are threaded into the pole pieces, lock nuts on these serving to securely clamp the brass yoke piece against the core ends. Experience only can prove how much of an improvement this is over the usual adjusting means. The Kellogg Switchboard & Supply Company has obtained the patent for this ringer, by assignment.

SELECTIVE SYSTEM.

Fig. 2 shows a novel sort of selective system, in this case arranged for four stations. Each station is equipped with a special

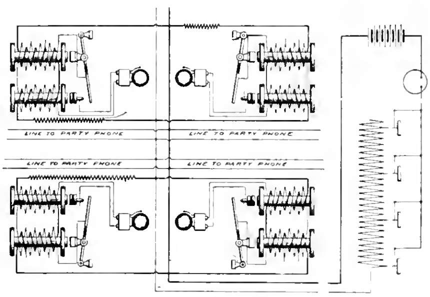

FIG. 2.—GÉHRUNG SELECTIVE SYSTEM.

limit relay, the contact of which controls the local bell circuit. The limit relay is comprised of two electromagnets, each with its own armature. One of these armatures carries the contact anvil, while the other carries the contact. The electromagnets at each station are in series and are bridged on the line through a greater or less resistance. The condition for sounding a signal is that while the contact anvil armature at the desired station is not attracted toward its magnet, the contact armature is attracted toward its magnet. In order to bring this about the magnets are adjusted to begin to respond at definite currents and are so arranged that as the current at which the anvil magnet of one station just fails, the contact magnet of the next succeeding station just operates. For example, when station 1, shown in the lower left-hand corner, is desired, the operating current is put on the line at the central office through a resistance such that while the anvil armature of No. 3 fails to respond to its magnet, the contact armature responds, causing a closure of the bell circuit thereat. At station No. 4 at the right of No. 3 neither armature responds and thus the bell contact remains open, while at both Nos. 1 and 2 both armatures respond and thus the anvil is kept from contact with the contact point and the bells fail. The patentee of this system is J. A. Gehrung, of St. Louis.

St. Louis Street Railway Convention.

A decision to hold the 1904 convention of the American Street Railway Association at St. Louis was reached at the meeting of the executive committee of the association held at that city recently, as already noted. It was found that the World's Fair management would designate October 12 as "American Street Railway Association Day," thus making it one of the formal days of the Exposition. They also promised the association their cordial co-operation in making the meeting a success in every respect, and also placed at the disposal of the association for its meetings "Recreation Hall," which is in the great building known as "Festival Hall," and is located in the central part of the grounds. For the meetings of the subsidiary associations they offered smaller halls in the same building. As October is a very attractive month in St. Louis, it was decided to accept these offers and designate October 12 and 13 as the days of the convention. It was also proposed to make the entire week commencing with Monday, October 10, one which would offer special attractions to street railway men, and to this end it has been suggested that the American Railway, Mechanical and Electrical Association should hold its convention on Monday and Tuesday, October 10 and 11, and that the Street Railway Accountants' Association should hold its meetings on Friday and Saturday, October 14 and 15. The annual banquet will be held on Thursday evening, October 13.

The Southern Hotel has been designated as the headquarters of the association. There are a large number of other hotels, however, among them "The Inside Inn," which is the large building erected within the Exposition Grounds for the accommodation of visitors, and which will undoubtedly be patronized by a great many people. The secretary of the association is now preparing a circular which will give such information as will enable any person by the exercise of a little care to be well located during "Convention Week" at the Fair. The association will also send to all members before the meeting, a book giving the names of every hotel and lodging house in St. Louis, their location and the rates per day and week, and will exercise every endeavor to have all attendants at the convention well cared for. Assurances were also secured from leading hotels in regard to rates, and were regarded as very satisfactory.

The Metric System.

We have received from Mr. George W. Colles a lengthy communication on the metric system, in which it takes issuance with some statements in favor of the system which have appeared in these columns. The arguments may be condensed as follows:

The favor shown by the British Colonies for the metric system is of no moment, for, as far as that system is concerned, there is no more connection between Great Britain and Canada, or Australia, than between Great Britain and the United States. He states that the action by the Colonies has been in a series of petitions and resolutions, legislative or otherwise, and the Colonies that have acted are confined to the Transvaal, Australia, Cape Colony and New Zealand, in which "raw ochlocracies about any kind of law or propaganda may be expected to take root." The adoption by Great Britain of the metric system has, he asserts, been vigorously urged for more than fifty years, but without effect; on the other hand, the Imperial system of weights and measures, first established in 1824, has been steadily improved and consolidated by successive further acts of Parliament, "which leave no doubt as to the sort of progress that Great Britain is really making." It is stated that the comparison of the metric system to a labor-saving machine is an old stock in trade, and has been knocked in the head so many times that it "ought to be dead, even if it isn't." Prof. Charles Davies, who is pronounced one of the most eminent specialists of education that this country has produced, opposed the labor-saving view, and it is stated that the University Convocation of the State of New York, which is pronounced an eminently competent body in education, reported its emphatic opposition to the system on this particular ground.

CURRENT NEWS AND NOTES.

DISCUSSION OF INSTITUTE PAPERS.—In the report in our issue of April 2 of the discussion of the Institute papers read at the March meeting, the several references to remarks stated to have been made by Prof. D. C. Jackson should have credited the authorship to Mr. William B. Jackson instead.

THE TROLLEY AND THE FARM.—According to State Statistician Johnson, of Indiana, the dearth of farm hands in that State is due to the rapid development of the interurban electric railway. The uncertain hours of farm work, it seems, cause men holding steady jobs to give them up in order to assist in building an electric railway, and then permanently to abandon their former line of work if a position as motorman or conductor is available, or they can secure any other berth on the road.

MOVING A MEXICAN TOWN.—Advices from Mexico say: "The Mexican Light & Power Company, which is installing the great water power and electric transmission plant in the State of Puebla, ninety miles from the City of Mexico, has just completed moving a town of 1,000 population. The engineers found that the town of Necaxa occupied a site particularly suitable for the necessary reservoir, and the company forthwith purchased the entire town and moved it to a new location. All the buildings, including the Catholic Cathedral, were razed and reconstructed on the new site. The new town bears the name Canadita. The initial capacity of the plant will be 45,000 hp. F. S. Pearson, of New York, is the engineer."

CHICAGO MUNICIPAL OWNERSHIP.—The chief interest in the recent city election in Chicago centered in the vote on the proposed municipal ownership of the street railways. In this connection what is known as the "Mueller law," passed by the last Legislature, was submitted to the people. The law authorizes cities in Illinois to construct, own, operate and lease street railways, and to provide the means therefor. The vote stood 152,433 for and 30,104 against the proposition. On the proposition that the city should at once take over the street railways into its control the vote stood 120,744 for and 50,893 against. For the temporary licensing of street railways until such time as the city is prepared to take them over, the vote was 120,181 for and 48,056 against.

SCENIC TUNNEL AT NIAGARA.—The new scenic tunnel, run under the Horseshoe Falls of the Niagara, was recently opened for inspection of the engineers and park authorities by the Ontario Power Company. This tunnel cost the power company over $25,000, and is designed to present the grand scenic beauties of the cataract as never before seen. A shaft was sunk 127 ft. from the interior of the Table Rock House, and from the bottom the tunnel runs a distance of over 800 ft., following the contour of the Horseshoe, and coming out under the first heavy fall of water over the brink. Small lateral tunnels run from the main one into the gorge. The shaft has been walled up and an electric elevator installed, from the foot of which to the mouth of the main tunnel is a broad plank walk. Immense glass observation rooms will be constructed at the mouth of the lateral tunnels, where the visitor, reclining in an easy chair, can view the fierce onrush of the great torrent.

ANGLO-FRENCH TELEPHONY.—The telephone service between London and Paris was extended on April 11 to the provincial towns in England and France, between which communication is at present practicable. The charge will be $1.92 for a conversation of three minutes, except in the cases of Bordeaux, Lyons, Marseilles and St. Etienne, when $2.40 will be charged. Subscribers in London will be able to communicate with the following towns: Amiens, Armentières, Bethune, Bordeaux, Boulogne, Caen, Calais, Cambrai, Chartres, Denain, Dieppe, Dijon, Douay, Dunkirk, Elbeuf, Havre, Lens, Lille, Lyons, Marseilles, Nancy, Orleans, Paris and suburbs, Roubaix, Rouen, St. Etienne, St. Quentin, Tourcoing, Tours and Valenciennes. Communication will at the same time be available between the post offices at Birmingham, Bradford, Brighton, Bristol, Cambridge, Cardiff, Derby, Hull, Ipswich, Leeds, Leicester, Liverpool, Lowestoft, Manchester, Newport (Mon.), Norwich, Nottingham, Sheffield, Southampton and Yarmouth, and renters of wires into those offices on the one hand and Paris and certain of the above-named French towns on the other.

TRANSMISSION LINE MEETING IN CHICAGO.—The Chicago branch of the A. I. E. E. will hold a meeting the evening of April 26 to discuss "High-Tension Lines."

STREET RAILWAY CONVENTION.—The annual convention of the American Street Railway Association is to be held at St. Louis, Mo., on October 12 and 13, with headquarters at the Southern Hotel. Secretary T. C. Penington announces that a circular on the subject will be issued in a few days.

HIT BY A SHOE.—Brides and bridegrooms have been known to be seriously injured by the blow received from old shoes thrown after them for luck, or to express the jealous disappointment of the thrower. But for dangerous missiles, of this kind, the palm should be awarded apparently to those used on the Brooklyn elevated system. One of these shoes, accidentally detached from the car, fell on a mounted policeman, smashed his hat, cracked his skull, and sent him into hospital badly wounded.

N. E. L. A. QUESTION BOX.—The interest in the "Question Box" of the National Electric Light Association is indicated by the fact that the preliminary list of questions for consideration at the coming Boston meeting numbers almost 450, the greater part referring to station operation. We understand that a large proportion of the questions have already received answer in communications, thus showing that the interest is not only on the part of those who "want to know." The section of the transactions comprising this feature should be of unique value to members of the association, and in itself tends to largely increase the membership.

EQUIPPING ILLINOIS CENTRAL.—It is reported from Chicago that the Illinois Central is negotiating for twenty motor cars for use in the suburban service of the company. It is said that the order for the motor cars has been given to the General Electric and that the order will be increased to forty motors within a year. It is well known that the Illinois Central has had a standing offer to adopt for the suburban traffic any electric system which could be demonstrated to be equal to the work. If electricity is adopted as a motive power it is expected that the suburban trains eventually will consist of electric motors drawing steel side door cars, the latter being practically indestructible. The conditions of traffic in and around Chicago are regarded as very favorable for electric traction.

MENELIK'S TELEPHONE.—An interesting report has been received by the Navy Department from Lieut. Hussey in command of the escort for United States Consul R. P. Skinner, who recently visited Emperor Menelik, of Abyssinia for the purpose of negotiating a treaty. One of the most surprising things in connection with the expedition was the fact that the Emperor was kept informed by telephone of the progress of the American party. Three days were spent at Harar, where the Emperor's nephew called up his uncle by long-distance telephone to tell him that the Americans were coming. The Americans were met in state outside of the royal settlement and escorted to the Emperor, the time arrangement of the programme being made possible by the use of that great civilizing agent—the telephone.

WIRELESS TELEGRAPHY IN THE WAR.—According to the London *Electrician* of March 25, "The longest press message yet transmitted by wireless telegraphy appeared in last Monday's *Times*. It was about 1,400 words in length and had been transmitted by wireless telegraphy from the *Times* dispatch boat with the Japanese fleet to Wei-Hai-Wei, and thence by ordinary cable. The *Times* not only commissioned a dispatch boat so as to secure early news from the seat of the war, but also enterprisingly wired to the De Forest Wireless Telegraph Company in America to fit up an installation upon it, and a corresponding station on the mainland at Wei-Hai-Wei. The De Forest Company claims for this apparatus a speed of from 20 to 30 words per minute, and probably the range of a ship's installation would be at least 100 miles—possibly greater if local circumstances are propitious. The stations are attended to by members of the De Forest Company's staff, and although not completed quite so quickly as was anticipated at the *Times* in London, to judge by the result in Monday's paper it should now be working most satisfactorily."

LETTERS TO THE EDITORS.

Individual Motor Drive.

To the Editors of the Electrical World and Engineer:

SIRS:—Referring to my letter published in your issue of March 12 and Mr. Cooper's criticism of the same in your issue of March 26, I would like to state that whether or not motors can be obtained that will operate over a wide range of speed without sparking under weakened field, is not a question of theory but one of fact. I can testify to having seen and tested such motors in practical operation, as well as under a controllable generator load.

In one of these tests a motor frame rated as 10 hp at 825 r.p.m., with full field strength delivered 3 hp at speeds varying from 250 to 1,100 r.p.m. This motor was belted to a generator whose load was varied so as to keep approximately 12 amp. at 220 volts flowing through the motor armature. The field current was varied by the rheostat from 1.05 to .3 amp., resulting in the speed variation above mentioned. The load was then increased to 18 amp. in the motor armature, with the field current remaining at .3 amp., resulting in a slight falling off in speed, and so little of sparking at the tip of the brushes that it would not be noticeable except by very close scrutiny. This motor weighed approximately 1,050 pounds, and can be purchased for a trifle over $200, and is a perfectly practical and commercial device. I have also seen in practical operation many other motors whose speed was regulated over a wide range by altering the shunt field strength.

The 5-hp motor to which I referred in your issue of March 12 was tested by both the superintendent and first assistant engineer of the Cutler-Hammer Manufacturing Company before I wrote you about it. This company is at least alive to the fact that the variable-speed, constant-voltage motor has reached a practical, commercial stage, and it has developed a special drum controller for use in connection with these motors for driving various machine tools, etc., which has already entered largely into use; 14 will be in operation at the St. Louis Exposition shortly after May 1, where they may be seen. The horse-power capacity of the motors to be used with these controllers varies from 1 to 10, and the speed variation from 2 to 1 to 4 to 1. Motors can be obtained of at least one manufacturer that will commutate well over a speed variation as high as 6 to 1. So much for facts.

Now for Mr. Cooper's criticism of my rules for determining the size of suitable motors. Reference to these rules as printed in your issue of March 12 will show that I specifically limited them to motors designed to operate at variable speed under variable field strength, within, of course, the limitations of speed for which the motors were designed. The rules which I drew up were intended to be up to date, and are not applicable to motors designed in the nineteenth century.

It is true that I did not state how to design a satisfactory variable-speed motor, for, to be candid, I do not know how, and would not tell if I did. I do know, however, and stated plainly, that there are a great many elements of design which affect the degree of sparking. I know, further, that there has been no radically new discovery made which enables expert designers to produce motors that commutate well under wide variations of field strength. This result has been attained by considering each and every factor of design that tends to reduce sparking with the utmost care, and applying expert skill of the highest order to produce a harmonious blending of all these various factors. It is enough to proclaim that certain expert designers have succeeded, and that the great boom in the individual application of motors, which Mr. Cooper states would result, is now due.

MILWAUKEE, WIS. H. H. CUTLER.

Oerlikon Vertical Motor-Generators.

To the Editors of Electrical World and Engineer:

SIRS:—In your issue of March 26 you are so kind as to publish an article descriptive of the vertical motor-generator sets as installed by our firm at Lend-Gastein. Unfortunately, an erroneous statement was made in the article on page 609 where you say: "The motors are of the synchronous type." As a matter of fact, they are non-synchronous. Will you kindly correct this in one of your next numbers. The motors have their rotor windings short-circuited upon themselves. The starting of the motor is performed by starting the generators, which are, of course, separately excited.

Oerlikon, Switzerland. E. Huber.

The Telephone Receiver in Electrical Measurement.

To the Editors of Electrical World and Engineer:

Sirs:—Having once investigated the use of telephone receiver for the measurement of capacity, inductance and resistance, I was much interested by Mr. J. A. Campbell's article on the "Shielded Balance" in your issue of April 2. I will not criticise the principle of the shielded resistance, but can say at once that such a device will be of little service in improving the utility of the telephone receiver in connection with the Wheatstone bridge. The trouble is mainly in the electromagnetic induction between various parts of the bridge, and the capacity effect is comparatively small in ordinary cases, except when using extremely high e.m.f. To avoid the electromagnetic induction in such case by means of magnetic shields of iron is, of course, physically impossible.

In short, it is a mistake to cling to the Wheatstone bridge when we have to do with alternating current, and the right solution is to be found in the use of differentially-wound telephone receivers on which I contributed an article to your issue of May 23, 1903. On further investigations, my methods proved wonderfully accurate for measuring capacity, inductance as well as resistance, and I could even measure with accuracy the capacity of a spherical conductor only 3 inches in diameter isolated in space in a laboratory of Tokio Imperial University. I sincerely wish that Mr. Campbell would try a differential receiver, in which, I am sure, he will find a very practical thing.

I take advantage of this occasion to correct an error. In my former paper I stated that a certain relation between capacities and resistances was required for the measurement of capacity, but I found afterward that such was not at all necessary, as may be easily proved.

Schenectady, N. Y. H. Ho.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

Dynamos, Motors and Transformers.

Output and Design Coefficient.—Press.—A communication in which the author proposes the following output equation: Output in watts equals the "design coefficient," multiplied by revolutions, multiplied by the square of the diameter of the armature, multiplied by the sum of the core length and the length of the end connections. The design coefficient equals the final temperature rise multiplied by the radiation capacity of unit surface at unit peripheral speed, divided by the product of the armature loss factor and the total loss of efficiency factor.—Lond. *Elec.*, March 25.

Variable-Speed Motors.—Burleigh.—An illustrated article on speed variation of speed current motors. To obtain the best results, the reactance volts at maximum speed should not exceed 2.5 and the ampere-turns per pole should never be less than the ampere-turns required for the gap. For motors up to about 20 hp a four-pole machine with series-wound armature and four sets of brushes seems to be the best. At a voltage of 220 a very good motor can be fairly economically produced with a speed ratio of three to one or even four to one, while a speed ratio of two to one is quite high enough for a 500-volt motor. The author gives the complete data of the design of a 4-hp motor for 400 to 1,200 revolutions at 110 volts and for a 6-hp motor for 300 to 900 revolutions at 220 volts (making use still of the old Kapp lines).—Lond. *Elec. Rev.*, March 25.

REFERENCE.

Tandem Connection of Induction Motors.—Müller.—A mathematical article in which the author refers to the fact that the well-known Heyland-Behrend circular diagram of the induction motor in its original form does not apply to speeds above synchronism. He now shows that for the tandem connection the diagram for speeds above synchronism also differs from the ordinary diagram.—*Elek. Zeit.*, March 24.

Lights and Lighting.

Mercury Vapor Lamp.—An illustrated description of a new type of mercury vapor lamp designed by Bastian and Salisbury (its efficiency being lower than that of the Cooper Hewitt type and its chief commercial advantage being apparently the convenient shape of the lamp). Fig. 1 shows the lamp in its normal position. *E* is a spun copper bell-shaped cover which protects the internal mechanism from wet and provides a means for suspending the lamp and fixing the tubes and other devices. *G* is an ordinary glass globe. As shown in the illustration, the lamp is not at work, and the mercury in the tube, *T*, connects the two wires sealed into the glass. Fixed to one end of the glass tube is an iron plunger, *C*, which acts as a core to the electromagnet, *M*. The resistance, *R*, the electromagnet, *M*, the carbon filament lamp, *L*, and the mercury in the tube, *T*, are all connected in series. On closing the switch the core, *C*, is drawn up by the electromagnet; *T* being pivoted at *P* and the continuity of the mercury being broken, an arc is formed. The tilting of the tube is thus effected automatically. The pressure of the mercury vapor set up by the arc then forces the mercury up into the left-hand bulb and thus cuts out the auxiliary resistance, *R*. All these operations occupy but the fraction of a second. The carbon filament lamp, *L*, just above the mercury tube, is added for the purpose of overcoming the absence of red rays and this lamp is, therefore, under-run so as to make its radiation rich in the required red rays. An efficiency of 2½ cp per watt is claimed when the carbon auxiliary is not used

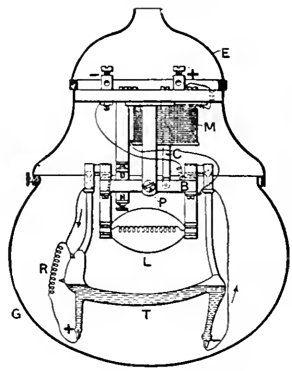

FIG. 1.—MERCURY VAPOR LAMP.

and of 1 to 1.5 cp per watt when the latter is used. Each lamp requires from 40 to 60 volts and 0.65 amp., the candle-power being 80. Lamps have been run both continuously and intermittently for over 1,500 hours and the inventors believe that the average life will be about 3,000 hours. The lamp is intended especially for side street lighting to compete with incandescent gas light. Editorially, it is stated that apparently the color defect has not been entirely overcome; "although the condition of the over-run carbon lamp does constitute a distinct improvement, yet the rays do not mix as well as might be expected and the resulting illumination is still of the nature of moonlight." The resistance of the carbon filament in series decreases the voltage across the terminals of the mercury tube and consequently the length of this tube.—Lond. *Elec.*, March 25.

REFERENCE.

Train Lighting.—Aliamet.—An illustrated article on the system of train lighting used by the Northern Railroad Company in France. The incandescent lamps are supplied with current from storage batteries placed in each car, so that the different cars are independent from each other. The storage batteries are charged in the stations and are connected in series for this purpose. Since the number of cars in a train changes from train to train and from day to day, and since on the stations either 115-volt direct-current or 85-volt two-phase current are available, it was necessary to transform the voltage so that it fits the number of storage batteries to be charged in each case. This is done by means of the Lanhoffer voltage transformer, the principle of which was described in the Digest last week. Drawings are given of this machine and of the connections used for charging.—*La Revue Elec.*, February 15.

POWER.

Electric Winding Machines.—GEORGI.—An illustrated paper read before the Glasgow Section of the (Brit.) Inst. of Electrical Engineers. Electric winding machines have made rapid headway during the last few years in Continental Europe, especially in the mines of Silesia and Westphalia. One great advantage of electric winding is to diminish very considerably the coal consumption, which can be brought down to about 1/3 of its original value if a modern generating plant is adopted. The author points out that the utmost security of working is required since the winding engines are not only used for the extraction of minerals, but also for transporting men. The speed of the machine will have to be regulated independently of the load; that is, independently of the current in the armature and with the utmost possible economy. These conditions are stated to be fulfilled in the system of Ilgner, with which it is possible to connect any number of winding engines to any kind of electrical distribution system, without diminishing the favorable steam consumption. The arrangement is based on the fact that a direct-current shunt-wound motor with a field of constant intensity and fed by an independent source runs with a speed directly proportional to the applied voltage and to the number of turns on the armature. The torque is, of course, a function of the current in the armature. If, therefore, a direct-current dynamo is arranged with independent excitation whose voltage can be regulated from zero to a positive or negative maximum by means of a field resistance, then a motor coupled on the same circuit and having a constant field, will run at a speed varying between zero and the positive and negative maximum. The starting of a machine is thus most economical and at any time the energy consumed is only equal to the product of the voltage by the current. In the Ilgner system the current taken from the supply drives a converter, composed of a motor, direct-current dynamo and a heavy fly-wheel. An automatic slipping device is fixed to the motor by means of which, should a dynamo call for energy, and, therefore, the current in the motor have a tendency to augment, the automatic friction clutch is released, the fly-wheel giving up kinetic energy. The weight and speed of the fly-wheel are calculated so that for a given slip the output of the motor remains the same. Thus the winding engine, as far as the supply station is concerned, may be considered as an ordinary motor of constant output. Owing to the motor being shunt wound, the speed is practically independent of the load. Illustrations are given showing the general arrangements of the governing and safety apparatus and also of the motor-driven winding apparatus.—Lond. *Elec.*, March 18.

Steam Turbines.—An illustrated description of the Riedler-Stumpf steam turbine, which occupies an intermediate position between the De Laval and Parsons types. In order to reduce the speed of the shaft, wheels of large diameter are employed, made of 10 per cent. nickel steel with the buckets cut into the periphery. Contrary to the De Laval construction, a rigid shaft is employed, which is supported by either one or two bearings. This is made possible by very accurate balancing. The center of gravity in a 2,000-hp turbine installed in the Berlin electric plant was specified to be within 0.004 in. of the geometrical center. This condition was very well fulfilled and the center of gravity could afterwards be made correct within 0.004 in. The nozzles are square in cross-section. The complete nozzle ring furnishes a full steam-jet ring. If partial admission is intended, the nozzles are united to an arc and the rotor buckets not played upon by the steam are covered, to decrease the ventilating resistance. Between the rotor and the nozzle the clearance is in the 2,000-hp turbine 0.12 in. measured radially and 0.4 in. when measured in the axis of the nozzle. The radial clearance has, it is said, been increased to 0.2 in. without affecting the efficiency. At brake tests of the 2,000-hp set, when the output was 1,917 hp a consumption of 17.6 pounds of steam per kw-hour was observed, the speed being 3,800 r.p.m.—Lond. *Elec.*, March 25.

Italian Hydroelectric Stations.—BIGNAMI.—A fully-illustrated description of the various hydroelectric stations of the Alta-Italia Company, which supplies current for lighting, traction and general power purposes to Turin and a great many towns in the neighborhood. Three-phase currents are generated at 450 volts and the voltage is then raised by transformers to 12,000. This was the voltage originally intended for transmission, but it was later decided to double the transmission voltage and therefore special transformers were interposed which raised the voltage from 12,000 to 24,000. The arrangement is shown in Fig. 2. The special transformers are

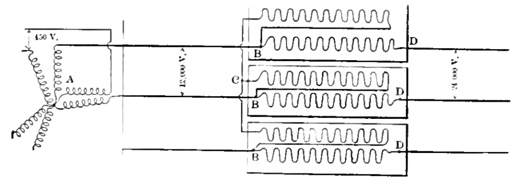

FIG. 2.—DIAGRAM OF TRANSFORMER CONNECTIONS.

single-phase with a transformation ratio of one to one. One of the windings is put in series with the line; the other winding is star-connected at one end to the corresponding circuit of the other transformers, and at the other end is connected with the 12,000-volt line. The arrangement is clearly shown in the diagram.—*Eng'ing Mag.*, April.

REFERENCES.

Gas Engine.—An illustrated description of the construction of the Nürnberg gas engine. It is stated that the makers guarantee a consumption of this engine of 2,100 calories (8,334 B.T.U.) per effective hp-hour running on blast-furnace gas. This corresponds to a thermal efficiency of 30 per cent. At 3/4 load the gas consumption is increased about 10 per cent.—*Power*, April.

Producer Gas and Water Power.—NAGEL.—A note in which the author points out that near coal mines producer gas power can be produced at about the price of power at Niagara Falls, and that the blast furnace will be of the same importance as a gas producer, as it is at present as iron producer. A 1,000-hp producer gas plant completely erected and including engine costs about $66,000; figuring depreciation, interest and working expenses with a coal price of $1 per ton, 1 hp for 24 hours will cost 5.55 cents.—*Electrochem. Ind.*, April.

Lubricants.—An article by Doane on the selection and testing of lubricants and another article by Davis on lubricating oils and their properties; how to test them and detect adulterations.—*Power*, April.

TRACTION.

Accident on Paris Underground Railway.—A long editorial, summarizing and criticizing a report of the technical committee which had investigated the disaster on the Paris Metropolitan Railway in August last. A summary is first given of the causes of the accident, and the lessons from the disaster are summarized for the prevention of similar accidents. The investigating technical committee lays the greatest stress on the requirement that it should be possible for the train staff to cut the current off the conductor rail at any point. For this purpose, it is suggested that the rail should be cut up into a number of separately fed sections, such that not more than five or six trains can be on any one section, and that every train shall carry a "short-circuit bar," which can be dropped across the conductor and running rail in case of need and so actuate the circuit-breakers controlling the section. The committee also urges that the lighting of the stations and tunnels should be provided from a number of sources, some of them entirely independent, not only of the traction supply, but even of the company's generating and sub-stations. It appears that the committee considers that the non-inflammable car is at present hardly attainable, so that short-circuits must be expected, and when they do occur some risk of fire is unavoidable. The writer of the editorial thinks that the committee has inverted the proper order of the measures required and that the essential condition of safety would be to design and equip the motor cars in such a way that ignition of combustible material is hardly possible. "With rubber-covered cables boxed in with wood a shoe that cannot be readily lifted from the rail, and circuit-breakers or fuses set for too heavy a current, it is conceivable that a short-circuit may put a car into a blaze in a few seconds and constructions carrying such risks must be avoided." It is also pointed out that from what happened it appears that neither train men nor the station staff had been instructed how to deal with an electric fire.—Lond. *Elec.,* March 25.

Rail Bonds.—HARRINGTON.—The conclusion of his Franklin Institute paper giving a summary of commercial rail bonds. Illustrations are given of special rail bonding tools and the ajax bond and the Camden & Suburban Railway bond are described. No. 1 of the latter consists of a square copper casting with two grooves from 4/0 B. & S. gauge copper wire; the casting has a 1 1/16-in. hole in the center. A cast-iron casting with corresponding grooves and hole is provided. The bond is applied by grinding off the web of the rail with an emery grinder and treated with Edison-Brown alloys, serving to amalgamate the surface of the rail and fill valleys and depressions and irregularities of the surface. The 4/0 wires and the copper casting grooves are also treated, the whole is then bolted to the web of the rail with a one-inch bolt, using a lock washer. The bond plates are located each side of the fish or joint plate and are connected by two 4/0 wires. Results of tests are given and Conant's method of bond testing is described as well as the method used by the Camden & Suburban Railway. The latter simply uses a car having mounted therein a barrel of water, rheostat included in circuit, a Weston ammeter, also a Weston voltmeter to obtain line voltage. A small truck with wood framing having two axles and 33-in. wheels on 3-ft. centers, with a Weston millivoltmeter located in the car and having its terminals connected to the axles of the small truck, the car is run so that the small truck will trail between car and power station. As all readings are taken relatively, that is, comparing readings of equivalent joint lengths and solid rail lengths, nothing need be done except to run and make notes.—*Jour. Franklin Inst.,* April.

REFERENCES.

Italian Electric Railways.—A note stating that a new electric railway will be installed from Rome to Naples. Energy will be derived entirely from water power. Another Italian electric railway has been opened from Naples to the base of the old funicular railway. The first and the last section of this line are adhesion roads, while the middle part is a cog wheel line. Gas power is used and for the production of the gas, two Dawson gas generators of 200 hp are employed. They supply gas to two engines coupled to two direct-current dynamos, which are operated in parallel with a storage battery.—Lond. *Elec.,* March 25.

Large Tramcar.—An illustrated description of a tramcar constructed by the Hartlepool Electric Tramways Company, and having a seating capacity of 84 passengers, 42 inside and 42 outside. The total cost, exclusive of trucks, was $700.—Lond. *Elec.,* March 25.

Train Lighting.—See the abstract under "Lights and Lighting."

INSTALLATIONS, SYSTEMS AND APPLIANCES.

British Central Station.—An illustrated description of the municipal electric station of Sunderland. The old plant contains 11 steam-driven generators aggregating 2,165 kw, while the new and principal station is equipped with five direct-current dynamos aggregating 1,280 kw, and three 5,500-volt, three-phase alternators with an output of 2,250 kw. The total capacity of the two stations is, therefore, 5,695 kw. The system has been, until recently, partly the original three-wire, 110-volt system, and partly a two-wire, 220-volt system. The original three-wire system has now been done away with, however, and a uniform system of distribution is obtained from two wires at 220 volts. This system has been adopted partly on account of the large demands which may be expected from the 21 shipbuilding and engine works in the borough, a large number of which were already electrically equipped with 220-volt motors driven from the works' own generating plant; and partly because of the steady development towards sub-station distribution in Sunderland. The principle is to generate three-phase currents at one station at 5,000 to 5,500 volts and transmit to sub-stations, where the current will be transformed by motor-generators and distributed to areas, the radius of the largest area not exceeding 5/8 of a mile. In each of these sub-stations will be a large storage battery. Two of the largest shipbuilding works are already connected to the station, one containing 22 motors with an aggregate capacity of 520 hp, the other 23 motors of 445 hp. Two large sub-stations have already been erected capable of accommodating plants to the extent of 2,500 kw.—Lond. *Elec.,* March 25.

ELECTRO-PHYSICS AND MAGNETISM.

Thermoelectric Forces in a Heated Wire.—SCHNEIDER.—Some remarks referring to a former article of Egg-Sieberg, who described a number of experiments in which a uniform metallic wire was connected to a galvanometer and by heating the wire under certain conditions thermoelectric forces were observed. Egg-Sieberg believed that the source of the current was in the unsymmetrical drop of temperature on both sides of the heating point. The author shows that this is not correct, and that also in this case there exists a contact of two mechanically and chemically different bodies, since when an iron wire is heated the iron is partly charged into oxide. From this point of view all the phenomena may be explained.—*Elek. Zeit.,* March 24.

REFERENCE.

N-Rays.—Lummer points out a source of error in the observation of N-ray effects which may easily mislead the observer. It is the conflict between the rods and cones of the retina in viewing a faintly luminous object.—*Phys. Zeit.,* March 1. Bichat has examined a number of metals for their transparency to N-rays, and has found that they show a well marked selective absorption. This offers a ready means of isolating definite homogeneous beams.—*Comptes Rendus,* February 29; abstracted in Lond. *Elec.,* March 25.

ELECTRO-CHEMISTRY AND BATTERIES.

Aluminum.—BENNIE.—A description of a new process for the production of aluminum proposed by Gin. The metallic aluminum is obtained by means of reducing aluminum by a zinc-sodium alloy. The aluminum chloride is prepared from beauxite by means of chlorine by the same electrolytic operation which furnishes the zinc-sodium alloy. The chlorine and zinc-sodium alloy are prepared by electrolysis on one hand of the double chloride of zinc and sodium and on the other of the double chloride of sodium and potassium. These two operations disengage chlorine, the first supplying the zinc destined for the cathodic bath of the second, in which the zinc-sodium alloy is prepared. The reduction which finally yields the metallic aluminum also reconstitutes the double zinc-sodium chloride in such fashion that the various operations form a closed cycle with regeneration of the intermediate compounds.—*Electrochem. Ind.,* April.

Benzine Fires.—JUST.—In chemical cleaning works sudden fires sometimes start when the cleaned woolen materials are taken out of the bath. During the motion of the materials in the benzine, electrostatic charges are produced due to the friction, the benzine becoming negatively and the material positively charged. When the material is taken out, a spark occurs and ignites the explosive mixture of benzine vapor and air. Richter has found that such fires are prevented if 1/20th to 1/50th per cent. of oleate of magnesia is added to the benzine. The present author shows that this is due to the considerable increase of conductivity of the solution. He describes an experiment which shows that electrostatic charges which are being developed are quickly carried off to earth on account of the increased conductivity of the solution.—*Zeit. f. Elektrochemie,* March 25.

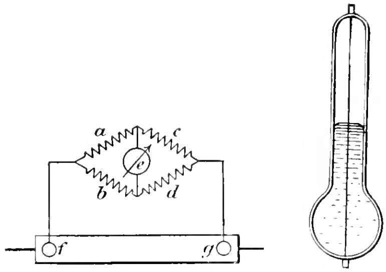
REFERENCE.

Preparation and Compression of Pure Gases.—HUTTON AND PETEVAL.—An illustrated paper on the preparation and compression of pure gases for experimental work. The authors deal especially with hydrogen, nitrogen, carbon monoxide and ethylene and describe the electrolytic production of hydrogen.—*Electrochem. Ind.,* April.

UNITS, MEASUREMENTS AND INSTRUMENTS.

British National Physical Laboratory.—A long extract of the annual report of this laboratory. While the work has prospered, the financial position gives rise to anxiety. In the electrical department, the experiments made on standard cells seem to show that differences remaining in the mercurous sulphate obtained from different makers, even when repurified in the standard manner in the laboratory, are the main cause in the differences observed between different standard cells. It is hoped that it may be possible to prescribe a standard method of preparing the sulphate, which will eliminate these differences. At present the electrical test of purity is more sensitive than the chemical. The construction of a standard ampere balance has been undertaken according to the designs of Jones and Ayrton. The coils of the balance consist of helices of bare copper wire wound on marble cylinders and its working depends very greatly on the accuracy with which these coils are wound and measured. The tests on insulating materials will be continued; the investigations now in progress relate to the distribution of temperature within the layers of the field coil of a dynamo or motor. Tests, as ordinarily made, give the mean temperature of the coils and it is desired to know by how much the maximum temperature differs in practice from the mean. Specimens of nickel-steel will be subjected to tests of electric conductivity, permeability, etc. In the optical division the first piece of research is the investigation into the conditions under which the pentane lamp may be considered as standard. Its intensity varies greatly with the quantity of aqueous vapor present and also with the barometric pressure and with the carbonic acid. The pentane lamp can only be treated as a secondary standard, and the next series of experiments will relate to the establishment of some primary standard, e. g., the radiation from a square centimeter of incandescent platinum at a definite temperature, or that from a "perfectly black body" at a definite temperature. In the electrical division of the physics department, the standard British Association air condensers were measured from time to time, their constancy being satisfactory within the limits of accuracy attained. The work in connection with the mercury standards of resistance was carried to a successful conclusion. Of these 8 are of Jena glass and three of verrefdur, the length varying from 60 to 120 cm. Fittings for each tube have been constructed enabling the measured resistance to either include or omit the "end correction," the value of the latter having been determined for the special kind of connecting cups used. The result of the observations on the whole 11 tubes shows that the difference between the international ohm, as defined by a uniform column of mercury 106.300 cm. long and 14.4521 grams mass at 0° C. is known to about 0.001 per cent. The platinum-silver and manganin standards of the British Association were also tested and marked changes were noted in certain coils. In the thermometrical department the research work consisted mainly of a continuation of the investigation on the various high-temperature standards. In addition to the comparisons of gas and platinum thermometers investigations were made on the behavior of thermo-junctions for high temperature measurements, and in particular the junctions of platinum and platinum-rhodium obtained from the Reichsanstalt, where they had been standardized at a number of fixed points. The discrepancies between the instruments were found to be very small. Between the two types of instruments, least affected by temperature lag—namly, the platinum thermometers and junctions—the difference in one set of experiments, extending from 500 to 1,000° C., never attains 1° C. and the several series of independent measurements with different fillings of the gas thermometer concord as closely as could be expected.—Lond. *Elec.*, March 18, 25.

Direct-Reading Switchboard Instruments.—Edgecumbe and Punga.—The first part of a paper read before the (Brit.) Inst. of Electrical Engineers. The authors first discuss the accuracy which may be attained. The great difficulty which is met with in the design of electrical instruments is the smallness of the forces dealt with. The greater the force for a given weight, the smaller will be the frictional error, but any attempt to increase the forces beyond a certain point is almost invariably accompanied by increased electric errors, quite apart from the question of excessive power consumption. The authors give a table of the electrical errors of various types of instruments (due to hysteresis, change of temperature, change of frequency, and stray fields). In a second table they give data on power consumption of various commercial types of instruments. They then discuss the general features of permanent-magnet, moving-coil ammeters and voltmeters; the chief source of error to be guarded against is the variation with time of the springs and magnet. The number of ampere-turns required in the moving coil varies in practice from ½ to 1 ampere-turn. Under these circumstances, for any given size of coil the necessary potential difference at its terminals is inversely proportional to the sectional area of the wire used. A limit is, however, soon reached; firstly, owing to the fact that a decreased resistance means an increased current, and with it the chance of contact resistance troubles, and secondly, owing to the resistance of the letting-in springs or strips. The best results are obtained when the resistances of the coil and springs are to one another in the inverse ratio of their temperature coefficients. A method for getting over the temperatures error, which is due to Campbell, is shown in Fig. 3, where e represents the moving coil, while the points f and g are connected to the shunt. The arms, a and d, are composed of copper; b and c of a material having a negligible temperature coefficient. If the resistance of a, d and e be 3 ohms each, while b and c have a resistance of 1 ohm each, practically perfect compensation will be obtained. The resistance having



FIGS. 3 AND 4.—DIRECT-READING SWITCHBOARD INSTRUMENT.

as large a negative coefficient as may be desired can be constructed as shown in Fig. 4. It consists of a thermometer tube, inside which is stretched a thin platinum wire. Any increase of temperature causes the mercury to expand, and hence to short-circuit more or less of the wire according to the dimensions of the apparatus. The authors point out that unless carefully shielded, moving coil instruments are contrary to the usual assumption, very considerably affected by stray magnetic fields. The ordinary cast-iron case appears to be quite an efficient shield for switchboard instruments. The authors then discuss moving-iron instruments. Almost all the errors to which they are liable, apart from those of a purely mechanical origin, are traceable to hysteresis in the iron. They remark that it is often assumed that an instrument whose indications are practically independent of frequency will also be independent of wave form and vice-versa. While this is true for all errors which depend purely on self-induction, it is far from being true when the errors arise from the iron itself. They then discuss magnetic shielding and damping. The paper is to be concluded.—Lond. *Elec.*, March 25.

Use of Condensers in Alternating-Current Measurements.—Peukert.—An article on the application of condensers for providing a lower e.m.f. at the terminals of an alternating-current instrument, when making measurements on a high-tension circuit. The author first discusses the case in which a number of condensers in series are connected across a line and the measuring instrument is connected to the terminals of one condenser. If all the condensers are identical then the voltage is reduced in proportion to the number of condensers employed. This method has been employed by the Allgem. Elek. Ges., in Berlin, and also in connection with the electrostatic voltmeters of Kelvin, Ayrton and Mather. Another method is to connect the measuring instrument in series with a condenser. To make the reading independent of the frequency, an air condenser should be used, since its capacity is independent of the frequency. The formulas for both cases are given.—*Elek. Zeit.*, March 24.

Universal Shunt.—An illustrated description of a universal shunt designed by Rymer-Jones, a diagram of which is given in Fig. 5.

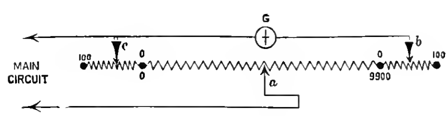


FIG. 5.—UNIVERSAL SHUNT.

The shunt is contained in a single box provided with two dials. The slide resistance coils on the left-hand dial consist of 99 coils of 100 ohms each, with one sliding contact arm, a, while, by way of vernier for slight alterations of the multiplying power of the shunt, there are, at both ends of these coils other extension resistances, each extension having a total resistance of 100 ohms. These extensions have each a separate sliding contact, both being actuated by the same handle, and so disposed that when one of these contact arms press on the zero stud the other arm is on its 100 stud. As the one contact moves from the zero towards 100 of its scale, the other moves from 100 towards 0 by equal distance. There is, therefore, always a total resistance of 10,000 ohms between the contacts, b and c, between which the galvanometer terminals are connected, while a

and c are in the main circuit. The vernier resistance studs, on which the marked contact arm presses, are arranged to give consecutive multiplying powers of 2, 3, 4, 5, 6, 7, 8, 9 and 10 ten-thousandths, after which the resistance is increased regularly by two ten-thousandths at a time. Thousandths and hundredths are read off the left-hand scale at a and tenths and units from the right-hand scale at b. The multiplying power of the shunt is the scale reading divided into 10,000; that is, the reciprocal of the scale reading, multiplied by 10,000.—Lond. *Elec. Rev.*, March 25.

Telegraphy, Telephony and Signals.

Wireless Telegraphy.—Hettinger.—A preliminary paper on a new theory of wireless telegraphy. The author endeavors to base his theory not on that of the propagation of electromagnetic waves, but considering the problem like an ordinary problem of alternating-current engineering in closed circuits. The action of the vertical wires is represented in this theory by a self-inductance and capacity. Each vertical wire forms a condenser, C_{AT} with the earth, and the two vertical wires at the transmitting and receiving stations form together a capacity, C_{AA}, as indicated in Fig. 6. The coherer is rep-

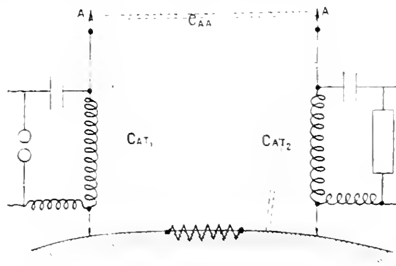

FIG. 6.—WIRELESS TELEGRAPHY.

resented as a condenser of high capacity in series with a resistance. The earth is introduced as a resistance and also forms the second plates of the two condensers, the first plates of which are represented by the two vertical wires. The author claims that in this way he is enabled to give a complete theory of the phenomena of wireless telegraphy on the basis of ordinary alternating-current engineering. —*L'Eclairage Elec.*, March 26.

Miscellaneous.

Aluminothermic Preparation of Pure Metals.—Goldschmidt.—An article on the production of pure metals free from carbon by the aluminothermic method and on their applications for various metallurgical purposes. The preparation is carried out in a sort of crucible in which several hundred kilograms of metal are reduced in the single operation. On account of the great rapidity of reaction, the operation is completed in scarcely 30 minutes. The principle is to use equivalent quantities of oxide and aluminum. But in practice the great facility with which aluminum alloys itself makes it advisable to use somewhat more of the oxide and less of the aluminum than would correspond to a mixture in equivalent proportions. The author discusses especially the production and uses of chromium, manganese and molybdenum. While pure chromium free from carbon is specially useful for the production of special steels, the applications of pure manganese are rather in the copper, brass and nickel industries.—*Electrochem. Ind.*, April.

Diastoloscope.—Charrie.—A note on a new optical instrument of remarkable power, called the diastoloscope. "It is a kind of eye piece which is attached to a microscope in place of the ordinary eye piece. Instead of lenses, it contains two cones on the same axis. The field of view shows a central blank space surrounded by a ring, in which the object under examination appears considerably magnified, although distorted. The distortion does not interfere with the mapping out of hitherto undiscoverable detail. The author reproduces figures of diatoms showing considerable dilatation and detail, and expects to realize magnifications of 6,000 diameters."—*Comptes Rendus*, February 29; abstracted in Lond. *Elec.*, March 25.

Thawing Water Pipes by Electricity.—An article giving a summary of the results obtained with this method last winter in various cities, especially Newark, Ottawa and Ogdensburg.—*Eng. News*, March 17. (Several references to this application of electric current were published in Electrical World and Engineer recently.)

New Books.

The Story of the Atlantic Cable. By Charles Bright. New York: D. Appleton & Co. 222 pages, 54 illustrations. Price, $1 net.

Mr. Bright has already written on the submarine cable in more voluminous form, but his larger volumes are not generally accessible to the American public. He now tells the story again very succinctly and well, and his book is a useful and desirable companion to that by Dr. Field, who may perhaps be said to have taken the American point of view. Aside from the historical portion, which is, of course, by no means new, though ever interesting as a narrative of a great achievement, there is much other matter of value, in handy condition. Mr. Bright gives details as to existing lines, tariffs, capitalization, etc. He states that the fifteen Atlantic cables now in existence represent $100,000,000, with a gross annual yield of $6,000,000. The reproduction of some of the old plates and portraits was a good idea. Mr. Bright's treatment of the subject is popular, and is intended for the general reader rather than in any sense for the technical student.

Moderne Gesichkpunkte für den Entwurf Elektrischer Maschinen und Apparate (Modern points of view in the design of electrical machinery and apparatus). Dr. F. Niethammer, München and Berlin. 192 pages, 237 illustrations.

Dr. F. Niethammer, who is favorably known from his writings, has attempted in this book to go over the entire field of electrical apparatus, and to give suggestions as to their design and construction. He has studied very carefully the designs of the last few years, and, basing his judgment on a thorough theoretical knowledge, he has selected the best of what he found here and there, and offered it to the engineer in a condensed and comprehensive manner. The problem, which the author has attempted to solve is: Is it possible to build economical and efficient machinery for any desirable r.p.m. for any desirable capacity, for any practical and reasonable voltage and for operating conditions as they are actually found?

After a short introduction, in which the electrotechnics are rightly called the technics of high speed and "par excellence," the question of efficiency, losses, heating, ventilation, the present maximum voltages and the insulation are taken up in general. We regret to notice that, although American makes are referred to in several instances, in general the author has overlooked the great importance of local economical conditions, price of labor and material and the bearing they have upon the economy of the design and the method of construction. The frequently great differences between the designs of European and American manufacturing companies are often due just to these points.

When treating heating and ventilation, an attempt is made to use as a basis the formula.

$$T = C\frac{A}{O}, \text{ or } T = C\frac{A}{O\ (1 + .1\ v)}$$

where T refers to rise in temperature, A to losses, O to total external surface, v to surface speed, while C is a constant. The constant, C, has a wide range of variation and values of C are given for different constructions. The author has himself proven, however, that these constants are rather unsatisfactory, by saying that the results do not agree very well with the formula. On the other hand, he is in favor of artificial cooling, when the results do meet the expectations. Why do they? Because, when they are found differing from the calculation, the artificial means (amount of cooling water, air pressure, etc.) may be varied, until the guaranteed temperature is obtained. This is certainly a very convenient way of getting the desired temperatures. The engineer does not require infallible constants which substituted in a formula will give him accurate results for any case. The careful determination of the efficient radiating surface, and a careful heat run, will give sufficient data for obtaining the heating of different sizes of the same type.

The chapter on insulation is rather meagre, and as to the present state of this subject it is not modern at all. We learn very little as to the different kinds of insulating material; the author is still in the mica age. The effect of heat on the break-down of insulating materials is not taken into account. In order to test the insulation of different apparatus, the author gives some figures for overpotential test. These are rather low according to American demands, and do not always express the endurance of the insulation. A heavy overload test is perhaps even more important for that purpose.

Electrical apparatus more particularly is taken up in the other chapters with a very keen eye and broad view. The reader will find many useful suggestions especially as to electromechanical construction. The best parts of the book are the chapters on polyphase generators and synchronous motors. The young designing engineer will find this book valuable, and the last pages give him some interesting advice and suggestions concerning shop practice, business organization, and the commercial part of engineering with many references to American practice, which the author seems greatly to admire.

BOOKS RECEIVED.

Die Metalle. By Dr. Bernhard Neumann. Halle: Wilhelm Knapp. 421 pages, illustrated. Price, 16 marks.

La Telegraphie Sans Fils. By Andre Broca. Paris: Gauthier-Villars. 234 pages, 52 illustrations. Price, 4 francs.

Les Chemins de fer Electriques. By Henri Marechal. Paris: Ch. Beranger. 556 pages, 516 illustrations.

Briquettes and Patent Fuel. By Philip R. Bjorling. London: Rebman, Limited. 254 pages, 121 illustrations. Price, $3.75.

Dynamomaschinen für Gleich und Wechselstrom. By Gisbert Kapp. Berlin: Julius Springer. 620 pages, 255 illustrations. Price,

Elektro-Akustische Untersuchnugen. By Robert Hartmann-Kempf. Frankfurt: Gebruder Knauer. 255 pages, 105 illustrations.

Die Elektrische Buhnen und Effekt-Beleuchtung. By Dr. Th. Weil. Leipzig: A. Hartleben. 256 pages, 205 illustrations. Price, 4 marks.

Wechselstromtechnik. By M. T. Zsakula. Leipzig: A. Hartleben. Four volumes. 264 + 216 + 200 + 200 pages, illustrated. Price per volume, 4 marks.

Essais Industriels des Machines Electriques et des Groupes Electrogenes. By F. Loppe. Paris: Gauthier-Villars. 280 pages, 129 illustrations. Price, 8 francs.

Compendium of Drawing. Chicago: By American School of Correspondence, Armour Institute of Technology. 410 + 477 pages, illustrated. Two volumes. Price, $3 per volume, $5 per set.

Practical Laws and Data on the Condensation of Steam in Covered and Bare Pipes. By Charles P. Spaulding. New York: D. Van Nostrand Company. 102 pages, illustrated. Price, $2.00.

Steam Turbine Power Plant for Boston Navy Yard.

An interesting departure in engineering practice by the authorities of the United States Navy, Department of Yards and Docks, is marked by the introduction of Westinghouse-Parsons steam turbines for furnishing power for lighting the buildings and yards, and power for operating dry dock pumps and miscellaneous machinery. The initial installation of this character is in process of construction at the Charlestown Navy Yard, Boston, Mass., and for the present one Westinghouse-Parsons turbine generating unit of 750-kw capacity will be placed in service. This turbine will be of the new short-barreled type and is now under construction at Pittsburg. A Worthington surface condenser will be employed, using salt water for circulation. The condensers will be located between the foundations, which consist of concrete piers. A running vacuum of 28 in. will be secured through the aid of a dry-air pump. Steam will be furnished at 150 pounds pressure by Babcock & Wilcox boilers in units of 350 hp, equipped with Roney mechanical stokers. Coil superheaters in the boiler settings will furnish to the turbine a superheat of about 100° F. The boiler house will be equipped with a complete outfit of coal and ash-handling machinery.

The present power plant is the outcome of an appropriation made in 1898 by Congress for a dry dock and pumping plant to be located at the Charlestown Navy Yard; the new plans for a dry dock equipment providing for a power plant located near the outer end of the new dock with piping connections to both old and new docks so that the one pumping plant would be able to handle them simultaneously or separately. During the period of construction of the new dock the Department of Yards & Docks at this Navy Yard underwent considerable enlargement necessitating an immediate increase in an electrical generating equipment for supplying light and power to buildings and departments.

In view of this situation, it was decided to supersede the dock pumping plant, originally provided for, by a central lighting, power and heating plant for the entire department, although retaining the dry dock pumping equipment which will now be electrically driven from the central station. It is also intended to supply from this plant electric light and power to the vessels docking which do not happen to be under steam. The power system as now under construction is, therefore, considerably more comprehensive than originally laid out.

The turbine plant will supply three-phase alternating current at 2,300 volts, this voltage being used for general distribution and for direct use in large motors, while for lighting lower voltage will be provided by transformation. The turbine generator will be served by a 37½-kw Westinghouse compound exciter unit.

The engineering work is under joint execution by the Department of Yards and Docks and the constructing engineers, Westinghouse, Church, Kerr & Co., who are installing the plant.

Wireless Telegraphy in the War.

During the recent demonstration of the De Forest wireless telegraph before the British Post Office between Holyhead, England, and Howth, Ireland, arrangements were made by the De Forest Company with the *Times*, of London, and Captain Lionel James, its famous war correspondent, then about to start for Yokohama. This contract demanded that two complete sets of wireless telegraph apparatus, manned by two expert operators, should be shipped to the front. Within ten days the full outfits, including even two kerosene oil engines, and weighing all told over four tons, were shipped express to Vancouver, where the men just caught the steamship *Empress of Japan*. At Shanghai, China, Captain James had chartered the little steamer *Hai-mun*, a two-master, on which topmasts were rigged to the height of 75 ft., all the vessel could safely carry. There the apparatus was transferred, and during the voyage north to Wei-Hai-Wei the two experts, Athearn and Brown, both New Yorkers, worked unceasingly until the ship's set was completely installed and in operation.

Capt. James' lieutenant, Mr. Fraser, had preceded him to Wei-Hai-Wei, and there the men found nearly complete a bamboo mast 180 ft. high, rigged in the best possible fashion, considering the unsatisfactory wood which alone could be obtained for that purpose, and the great dearth of necessary supplies. A pair of rough bungalows were thrown together by coolie labor, and the task was begun of moving the engine and heavy machinery from the dock to the promontory where stands the station. This point is some ten miles east of the town of Wei-Hai-Wei, accessible only by pony messenger, over a narrow and rocky trail. The utmost energy and ingenuity was required on the part of the English and Americans to get the Wei-Hai-Wei apparatus quickly installed. The fact that just three weeks from the date of landing at Wei-Hai-Wei, the *Times* printed a column-long dispatch from Capt. James, received by wireless is a tribute to the spirit and ability which is so characteristic of that correspondent and his staff. Since that time numberless dispatches have been flashed from the masts of the little *Hai-mun*, far out in the Corean Gulf, near Chemulpo, or even in company with the Japanese fleet in battle off Port Arthur.

Each set is of 1-kw capacity and comprises a 2½-hp Secor oil engine, a 60-cycle, 500-volt generator with separate exciter, oil transformer delivering 20,000 volts, oil transmitter key, regular Shoemaker-De Forest oscillator and syntonizer, electrolytic receiver, with relay and bell attachment and highly sensitive telephone receivers. The *Hai-mun* being without electric power, carried an oil engine, the same as the shore station.

It was the original intention to install one station upon one of the Sir James Islands in the Chemulpo peninsula and transmit thence to Wei-Hai-Wei, a distance of 175 miles, but Capt. James decided that an installation upon a boat would give him greater mobility and save long delays in getting dispatches to the transmitting station.

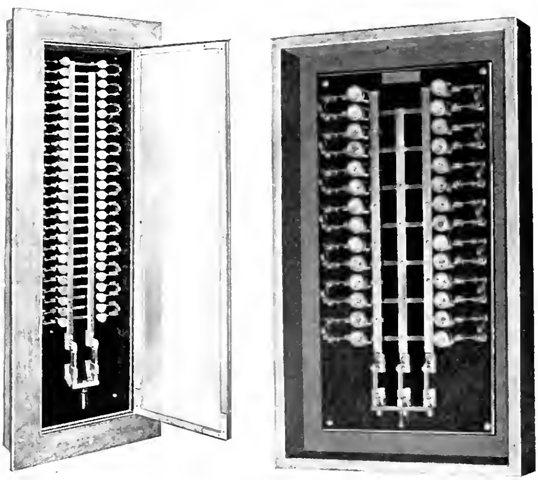
The De Forest apparatus in the Yellow Sea has not been exempt from serious competition by the Japanese wireless stations on board their vessels of war. Whether intentionally to interfere or in the ordinary operation of their stations there has been a continuous stream of wireless signals in that neighborhood, but the methods of syntonization employed in the De Forest apparatus, the speed with which the press dispatches are rushed through with the alternating-current transmitter—25 to 30 words per minute—(which greatly exceeds the speed of the Japanese system) together with the telephonic method of sound reading, have, it is said, enabled the American operators to send the longest wireless dispatches on record, without error or delay.

Barring an accident to the receiving mast on the Wei-Hai-Wei Peninsula from a typhoon, the *Times* news service by De Forest wireless system has been uninterrupted.

Capt. James' dispatches form a series of masterly and graphic pen pictures of the war, standing alone amid the mass of mutilated, conflicting reports which have come from the seat of conflict.

Fuse Plug Cabinet Panels.

The line of cabinet panels manufactured by the General Electric Company has been received with favor by contractors and architects throughout the country. These panels are furnished for 125 and 250-volt service, in a variety of arrangements and circuits. The distinctive feature is the employment of the Edison fuse plugs on the different circuits. The plug type of panel is considered to have an advantage over the cartridge fuse type in that the bus-bars and connections are placed considerably below the level of the tops of the plugs, thus rendering very remote the liability of a short-circuit. The fuse plugs furnished with the 125-volt panels are fitted with a mica cap, which enables one at a glance to know on what circuit the fuses

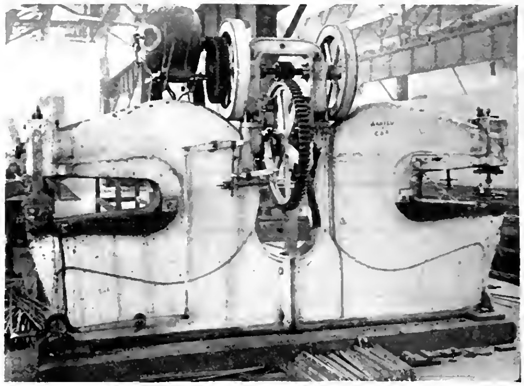


FIGS. 1 AND 2.—CABINET PANELS.

have blown. The 250-volt panels are fitted with a reloadable type of fuse plug easily inserted, without danger of shock. These panels are neat in appearance, compact and well finished; and owing to the nature of the Edison plug no injury to the panel itself can take place when the fuses blow. Fig. 1 shows a cabinet panel for 26 two-wire, double-branch circuits from two-wire mains with main and circuit switches, while Fig. 2 shows a somewhat smaller panel arranged for 14 two-wire, single-branch circuits from three-wire mains with main and circuit switches. The spacing of the different panels is in conformity with the results of the National Board of Fire Underwriters.

Punch and Shear Motor-Driven.

In the busy shops of the Charlestown Navy Yard are found many instances of the effectiveness of motor-drive as applied to punching and shearing machinery. The character of the work done is such as to subject the motors to very severe conditions of load and in every case they have answered all the demands made upon them. The accompanying half-tone shows a Long & Allstatter Company double punch and shear driven by a Crocker-Wheeler semi-enclosed 2-hp motor, wound for a pressure of 220 volts and a speed of 975 r.p.m. The machine does work up to punching a ½-in. hole in ½-in. iron, 35 strokes to the minute, or shearing a 1-in. round or a 3 x ½-in. flat bar. It will receive punching tools, or cross-cut or splitting shears. This type of machine is built with a throat from 4 to 30 in. in depth. The respective sides of the double machines are entirely independent, so that one side may be run while the other is idle or



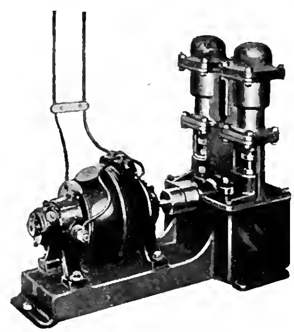
MOTOR-DRIVEN PUNCH AND SHEAR.

both may be operated at the same time. There is an automatic stop which may be used to arrest the slide at any point in the stroke.

The simplicity of attachment and convenience in operation of this motor-drive equipment is evident. It means a rapidity of control and a saving in floor space and permits a flexibility of shop arrangement, with respect to light, etc., that is out of the question with the old method of shaft and belting.

Direct Connected Electric Pump.

The engraving herewith illustrates an improved type of direct-connected electric pump for supplying tanks with water in office buildings, apartment houses, hotels and residents. The makers claim for it high efficiency, simplicity and durability. By a special switch



MOTOR-DRIVEN PUMP.

the apparatus operates automatically and starts pumping when the water in the tank is low, stopping when the tank is full.

The pump requires no foundation and can give service for months without attention. There are no oil cups, nor places to use a squirt can, lubrication being automatic. The outfit consists of an electric motor driving a duplex double-acting brass pump through a speed-reducing device which consists of a worm and gear running in a closed bath of oil. It is noiseless and by reason of its compactness and few parts is very reasonable in price. The space occupied is, length, 30 in.; height, 27 in.; width, 15 in. It was designed by Mr. Milan W. Hall, a pioneer in this line of work, and Mr. Charles S. Pease, of 13 Dutch Street, New York City, who is well known in the electrical and mechanical field, is general agent.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—Stock prices were firmer as a rule and showed considerable strength, notwithstanding the renewal of litigation in the Northern Securities matter. Support was given to prices by large interests and a favorable effect was produced by the declaration of the regular dividend on United States Steel preferred. There was little movement in the industrial list as a whole, although amalgamated Copper was supported moderately. In the Curb market the volume of business was larger and prices are generally higher, the heaviest operations being in copper shares. The rise in the latter was based on improved trade conditions. Among the declines are noted Otis Elevator, Interborough Rapid Transit and New Orleans Railway preferred. In the electric and traction stocks on the regular exchange there was no particular influence at work, and each stock fluctuated independently of all others. Allis-Chalmers common closed with a net loss of ½ point, while the preferred gained 3 points net, the closing prices being 7⅛ and 43 respectively. General Electric lost 1 point and Westinghouse gained 3½, the former closing at 163⅝ and the latter at 162½. These two stocks, it will be noticed, are just now nearly alike in price. Brooklyn Rapid Transit closed at 46⅛, this being a gain of 2 points, and Metropolitan Street Railway, 117, a gain of 5⅛. Western Union made a net gain of ½, closing at 89, and American Telephone and Telegraph lost 1¼, closing at 123. Following are the closing quotations of April 12:

NEBRASKA TELEPHONE REPORT.—The Nebraska (Bell) Telephone Company reports as follows for the year ended December 31, 1903:

	1903.	1902.	1901.
Gross	$1,049,907	$905,660	$754,971
Expenses	857,310	737,220	617,345
Net	$192,597	$168,440	$137,626
Dividends	115,768	99,000	81,222
Surplus	$76,829	$69,440	$56,404

The general balance sheet is given below:

	1903.	1902.	1901.
Assets:			
Construction	$2,238,974	$2,039,603	$1,674,796
Supply department	144,738	73,027	67,372
Real estate	192,547	158,910	141,317
Stock and bonds	1,867	2,100	100
Accounts and bills received	285,136	141,480	39,005
Cash	45,568	33,025	38,192
Total	$2,908,830	$2,448,145	$1,960,782
Liabilities:			
Capital stock	$2,196,900	$1,800,000	$1,500,000
Surplus	211,029	334,201	214,760
Reserve	400,237	239,672	218,779
Bills and accounts pay	100,664	74,272	27,243
Total	$2,908,830	$2,448,145	$1,960,782

LIGHTING IN CALIFORNIA.—The California Gas & Electric Corporation has consummated an important deal by the purchase of the systems of the Standard Electric Company, of California, and the United Gas & Electric Company, a monopoly in the supplying of electric power to twenty of the principal countries of the State. The Standard has a capitalization of $5,000,000 authorized stock and $5,000,000 in bonds, all issued and outstanding. The United Gas & Electric Company was capitalized at $2,500,000 in authorized stock, of which $2,286,000 is outstanding, and has $2,000,000 in authorized bonds, of which $1,100,000 is outstanding. The price paid for the two companies has not been made public, but it is said to be a high one. The Standard Electric Company's main plant is in Amador County. It supplies Sacramento and San Joaquin Counties, joining with the United Gas & Electric Company in supplying the counties around San Francisco Bay, its lines running through San José up the west side of the bay, into this city. Details and illustrations of the Standard system have been given in the pages of ELECTRICAL WORLD AND ENGINEER.

ELECTRIC SUPPLY COMPANY, of Savannah, Ga., has recently been incorporated for the purpose of extending its wholesale department and to add an automobile department, which has been accomplished. The paid in capital is now $25,000 and the prospects are exceptionally bright. Its sales extend over four Southern States, and the construction department is crowded with a number of large contracts. Among them is the lighting plant for Sandersville, Ga. The officers are as follows: David Wesson, of the Cotton Oil Company, president; Ed. M. Wilson, vice-president; Joseph S. Walker, treasurer and manager; E. C. Richardson, secretary. The board of directors is composed of wealthy and representative business men of this city. Among them are the following: W. V. Davis, treasurer Savannah Trust Company; Harvey Granger, of Granger Stubbs Lumber Company; William Kehoe, of Kehoe Iron Works; H. H. Bruen, of Patterson & Downing Co.; E. Moyle, merchant and capitalist; Capt. W. B. Stephens, a wealthy attorney, and others.

INDIANAPOLIS TRACTION TERMINAL.—The Indianapolis Traction and Terminal Company gross earnings increased $167,000 for the year ended December 31, 1903, over those of the constituent companies for the preceding year, and the months of January and February, 1904, each show an increase of about $10,000. The guarantee on the $5,000,000 Indianapolis Street Railway stocks is now 4 per cent. per annum, or $200,000, an increase of 1 per cent. over 1903, and rises 1 per cent. per annum up to 6 per cent. in 1900. A substantial surplus over the guarantee is stated as being earned and the proceeds of $3,000,000 5 per cent. bonds sold by the Terminal Company, which issue is a first lien on the terminal property, has correspondingly improved the position of the Indianapolis Street Railway 4s ahead of them.

CENTRAL AND SOUTH AMERICAN TELEGRAPH.—The annual report of the Central and South American Telegraph Company for the year ended December 31, 1903, shows as follows:

	1903.	1902.	Changes.
Gross	$1,072,134	$1,002,572	Inc. $69,562
Op. exp.	405,296	388,031	Inc. 17,265
Net	$666,838	$614,541	Inc. $52,297

There was expended from net earnings $62,710 for cable used in repairs and improvements, leaving a surplus after 6 per cent. dividends ($463,536) of $140,592. The total surplus December 31, 1903, was $820,912.

ATLANTIC COAST ELECTRIC.—Mr. James Smith, Jr., receiver of the Atlantic Coast Electric Railroad Company, has filed his report in the United States Circuit Court at Trenton, N. J., showing that the road is in good physical condition and capable of first-class operation. The report shows that the receipts for the year ending January 31, 1904, were $309,530, disbursements $262,064, leaving a balance of money on hand at the date of the report of $47,456. The report further shows that there were 4,048,671 passengers carried in the year.

BIRMINGHAM, ALA., BONDS.—The Birmingham, Ala., Railway, Light and Power Company has voted for an issue of $10,000,000 of 4½ per cent. bonds, with the proceeds of which it will take up the present $6,000,000 of 5 per cent. bonds, leaving a treasury surplus of $3,400,000 for the making of betterments to local properties. Holders of the present bonds will exchange bond for bond into the new issue and receive a bonus of $100 on each $1,000 bond besides. The project was launched with practically unanimous vote.

GEORGIA RAILWAY AND LIGHTING COMPANY, of Atlanta shows a gross for nine months ending December 31, 1903, of $1,424,286, a net of $605,860, and a surplus after all payments and deductions of $228,914.

BELL TELEPHONE BOND NOTES.—Speyer & Co., and Lee, Higginson & Co. have purchased from the American Telephone and Telegraph Company $20,000,000 5 per cent. 3-year secured gold coupon notes, to be dated May 1, 1904. The notes are secured by $25,000,000 of the company's present 4 per cent. bonds. The notes cannot probably be delivered before May 10. The $20,000,000 American Telephone notes are going very rapidly. Only a limited amount will be offered at the present price of 99 and interest, which is equivalent to a 5.33 per cent. basis. These notes are being offered in London, Paris, Berlin and Frankfort, and a large number of them are expected to be sold in these cities. The American Telephone and Telegraph Company had a number of offers from different syndicates, some of which were for bonds and some for notes, but the company showed its confidence in easier monetary conditions in the future by issuing 3-year 5 per cent. notes instead of a long-term bond. Although the payment for the entire amount will not be required of the syndicate at once, a good proportion of it will be paid immediately, and the syndicate has the privilege of anticipating the balance. The disappointed bond houses say that the price paid by the syndicate, which is comprised solely of Lee, Higginson & Co. and Speyer & Co., was 97½.

ELECTRIC COMPANY OF AMERICA.—The Electric Company of America net earnings for the fiscal year ending December 31, 1903, roundly $398,000, represent the amount applicable to pay the 6 per cent. dividend, requiring only about $240,000 per annum. It is understood that most of the $400,000 cash which the company had at the beginning of 1903 has been reinvested, the company having purchased small plants in the Middle West during the year. In 1902 interest on the cash loaned out and in bank constituted about $25,000 of other income, but except for a small item of "other income," the income in 1902 is entirely from operation of plants. The amount of dividends and interest received by the company, as the holding company, from the stocks and bonds of the subsidiary local lighting companies, is understood to be around $430,000. The corresponding income in 1902 was $366,587. The net earnings applicable to the dividend was $352,478. The company shows ordinarily between $300,000 and $400,000 bills receivable, against current liabilities of a few thousands dollars only.

NEW YORK TRANSPORTATION.—President Sanderson, of the New York Transportation Company, stated at the annual meeting last week that the company has about $750,000 in bank. About $300,000 has been spent in new construction, principally in connection with establishing the express business. The earnings from the express business so far have been somewhat disappointing, while the earnings from the vehicle department are increasing. Those who are familiar with the company's affairs point out that the franchises are worth more than the par value of the outstanding stock. The hard winter has unfavorably affected profits. The following directors were re-elected: Henry Sanderson, Harry Payne Whitney, Philip P. Dodge, George H. Day, G. Herbert Condict, George W. Wesley and William H. Palmer, Jr. The New York Transportation Company is capitalized at $5,000,000. It operates the Fifth Avenue stage line and a large electric automobile business.

CROCKER-WHEELER COMPANY INCREASES ITS CAPITAL.—A doubling of its capital stock, which has been $1,000,000, is announced by Crocker-Wheeler Company, of Ampere, N. J. The company, which is the largest of the independent electrical manufacturers of dynamos, motors, etc., was organized in 1892 by Dr. Schuyler Skaats Wheeler and Prof. Francis B. Crocker, on a relatively modest basis. It now has fifteen branch offices from Boston to San Francisco and does one of the largest businesses in the world in electric power apparatus. The capitalization was several times increased until in 1899 it had become $1,000,000. In view of the rapidly expanding business the stockholders have now decided to increase this amount to $2,000,000. The excellent balance sheet for last year was given in this department recently.

INCANDESCENT LAMP COMBINATION.—It would appear that in addition to those licensed to manufacture incandescent lamps under the General Electric patents in accordance with the recent pooling arrangement on prices, etc., are the Tipless Lamp Company, 316 Hudson Street, New York, and Monarch Electric Manufacturing Company, Warren, Ohio. So far as known, the following concerns have not applied for a license: American Incandescent Lamp Company, Kentucky Electrical Company, Germania Electric Lamp Company, Missouri American Electric Company, Moline Incandescent Lamp Company, and the Sawyer-Man Co., as already announced.

KEYSTONE TELEPHONE COMPANY, of Philadelphia, reports for the March quarter a net of $78,910, a gain over the corresponding period last year of $37,592.

DIVIDEND.—The Twin City Rapid Transit directors have declared a quarterly dividend of 1¼ per cent. upon the common stock, payable May 16.

Commercial Intelligence.

THE WEEK IN TRADE.—With the advent of more spring-like weather trade has received new life, and for the most part events have been favorable. The better weather conditions have increased retail distribution in the cities and helped farmers in their planting preparations. Wholesale and jobbing distribution have been strengthened in tone rather than in volume by the more favorable weather and the resumption of out-door work is helping distribution of iron and steel. The soft coal industry has also improved, owing to the removal of the fear of a general strike of miners. Collections, however, do not yet reflect any improvement in trade conditions, being especially backward in some sections of the Middle West, where recent floods have caused damage. *Bradstreet's* states that trade activity for this year's first quarter is behind that of the corresponding period last year. Failures exceed those of 1903 by 8 per cent. in number, though 5 per cent. less than those in 1902. Liabilities exceed those of a year ago by 70 per cent., and, owing to bank suspensions, are the heaviest since 1897. There were 201 business failures for the week ending April 7, as against 212 the week previous, and 163 the corresponding week in 1903. It is pointed out that the general level of prices in March for 8 out of 13 classes of products, including bread stuffs, meats, textiles, hides and leather and building materials, fell off about 1 per cent. for the month, but is still in excess of a year ago at this time, and near the highest for four years. The iron trade appears to be cheerful. Finished products are in moderate demand at leading markets. Among the other metals copper is firmer. Large producers have started an upward movement in prices based upon the recent heavy exportation and not upon any increase in demand here. Business, however, still lags. Quotations are 13⅛ @ 13⅜ c. for Lake; 13⅛ @ 13¼ c. for electrolytic and 12⅞ @ 13⅛ c. for casting stock.

EXTENSIVE PLANT FOR SILVERSMITH SHOPS.—The new plant now under construction by Dominick & Haff, silversmiths, at 543 West Twenty-third Street, New York, is to be installed with one of the most extensive electrical equipments hitherto utilized in the manufacture of silverware. The Crocker-Wheeler Company, through its New York office, 39-41 Cortlandt street, has secured the contract. There will be one 150-hp and one 50-hp engine type, 260 r.p.m., 250-volt generators direct connected to engines of 225-hp and 75-hp capacity, respectively, built by the Ames Iron Works. The motor installation will consist of 56 machines. There will be 37 constant speed motors and accessories and 18 variable speed machines. The latter will be of multiple voltage, which is to be furnished by a three-unit balancing transformer. The motors will range in capacity from ¼ hp to 30 hp. The average capacity will be 7½ hp. Most of the machines will be individual drive. They will be used for operating blanking presses, embossing presses, drop hammers, metal rollers and lathes.

THE CHIPMAN ELECTRIC PURIFYING COMPANY, of 13 Park Row, New York, and Schofield Building, Cleveland, Ohio, have appointed Col. W. S. Rogers manager of their Western office in Cleveland. This department includes all of the territory west of Pennsylvania. The Chipman process contemplates not only the purification of water under pressure for steam boilers, but has been worked out for municipal work in clarifying and purifying water for towns and cities. Plans are now being drawn up for a plant to furnish thirty million gallons per day for the city of Montreal. Mr. Rogers is well known as one of the pioneers of the arc lighting industry, having been in the old Brush Electric Company for 15 years. He has been watching the purification of water for electricity for some time, and has made up his mind that it is as far ahead of sand filtration as electric cars are of cable and horse cars.

EQUIPMENT FOR ATLANTA TERMINAL RAILWAY DEPOT.—The new Atlanta (Ga.) Terminal Railway depot is to be equipped with considerable plant for light and power purposes. Through the Atlanta office of the Harrisburg (Pa.) Foundry and Machine Works which is under the management of Glenny & Castanedo, two 150-hp and one 225-hp engines have been contracted for. The first engine will be direct connected to Westinghouse generators of 100 kw capacity each. The other engine will be direct connected to a 150-kw Westinghouse generator.

EQUIPMENT FOR MEXICAN MINES.—The San Felipe Mining Company, whose headquarters are in Philadelphia, and of which Colonel N. Z. Seitz is vice-president and general manager, is about to install an electric plant for the purpose of driving the mill drills, etc., on its mining properties located in the Ixtlan district, State of Jalisco, Mexico. Power will be derived from a hydraulic plant to be erected in the vicinity of the mines.

PELTON WATER WHEELS.—There are now running something more than 11,000 Pelton wheels in various parts of the world, in connection with electric transmission, mining, manufacturing and other industries, aggregating in excess of 1,000,000 hp. In the United States there are: California, Oregon and Nevada, 7,647 wheels, 708,370 hp; Washington, Idaho and Alaska, 623 wheels, 58,225 hp; Utah, Colorado and Montana, 176 wheels, 24,970 hp; Hawaii, New Mexico and Arizona, 208 wheels, 13,800 hp; Middle, West and Atlantic States, 146 wheels, 5,670 hp. In foreign countries there are: Mexico and Central America, 636 wheels, 152,905 hp; various South American States, 371 wheels, 24,660 hp; Australia, Japan and India, 484 wheels, 40,250 hp; East and West India Islands, 243 wheels, 30,250 hp; British Columbia and Nova Scotia, 52 wheels, 10,500 hp; England and South Africa, 77 wheels, 12,220 hp; Germany, France, Italy and Spain, 341 wheels, 4,820 hp; Norway, Sweden and Denmark, 36 wheels, 2,800 hp. The total is 11,040 wheels, 1,089,440 hp. Results in excess of 80 per cent. efficiency are reported by the Gold Stream plant of the British Columbia Electric Railway at Victoria, B. C. So well satisfied is this company that it has given the Pelton Company another contract to increase the output of the plant. This additional installation will consist of a water wheel unit for direct connection to a 1,000-kw, 400-r.p.m. Canadian-Westinghouse generator. This unit will consist of two wheels fitted with the latest type of Pelton buckets and needle nozzles both with pilot control, to operate under an effective head of 600 ft. The wheels will be mounted one on each end of the main shaft, which will be carried on ring, oiling, ball and socket generator type bearings. The wheels will be completely enclosed in sheet steel housings, mounted on heavy bed plates, designed also to carry the armature of the generator, thus making a complete iron-mounted integral unit with the Westinghouse engine type generator. This will give considerable reserve capacity to the plant which has been operating most successfully for a number of years.

THEATRE STEEL CURTAINS.—The Iroquois Theatre disaster in Chicago has led to some radical improvements in theatre drop curtains. Mr. Emery Stanford Hall, consulting architect for seven Chicago theatres, has placed in the Academy of Music a curtain of his own design and has awarded contracts for the placing of similar curtains in the Bijou, Alhambra and Haymarket theatres to the Sykes Steel Roofing Company. It is Mr. Hall's belief that it is dangerous rather than safe to use a very heavy gauge steel in the curtains, as was shown by accidents in "sticking." Mr. Hall's curtains weigh about 2 tons each, according to the size of the arch, and are made from 24-gauge black corrugated sheets protected on the stage side by asbestos. This curtain has no side bearings, but is under tension at all times between upper and lower cables, which hold it in place. Those from which it is hung are carried over pulleys high above the stage and support heavy counterweights in the basement, which keep them taut, also allowing for expansion and contraction. Under ordinary circumstances the curtain is raised by a motor connected through a worm gear with the drum around which the cables pass, but in case the motor should get out of order, by pulling a controlling rope attached to the lever of the drum the latter is disengaged from the motor and the curtain can be raised by hand. An electric button is placed on every fly floor and also at a point in the house, each button having the right of way over the rest of the machinery, so that by touching it the curtain may be instantly lowered. The lowering is effected by counterbalancing weights which weigh 200 pounds less than the curtain, allowing for friction and permitting it to fall by its own weight without shock to the stage floor. The motor which raises the curtain runs at four speeds and is controlled by switches in the flies.

MEXICAN LIGHT AND POWER PROJECTS.—A number of projects are being considered at present for the construction of electric lighting and power plants in various parts of Mexico. Steps have been taken by the municipal authorities of Lagos, a city of 20,000 population in the State of Jalisco, for the installation of a light and power system. At Real del Monte, which has about 4,000 inhabitants in the State of Hidalgo, a plant is also to be built. The State government has contributed $3,500 towards the undertaking. Longinos Gonzales, of Tescaltiche, State of Jalisco, population about 10,000, has filed an application with the State authorities requesting the necessary permission to establish a light and power plant. Power will in this instance be generated by steam. Zacatlan, a city of some 25,000 people, State of Puebla, is to have a municipal light and power system. Plans have already been drawn up by the city council for submission to the State government for approval. The Compania Maustral de Guadalajara, which operates a 2,000-hp hydraulic plant at Las Juntas for the purpose of transmitting current to Guadalajara for lighting purposes chiefly, is about to let contracts for 2,000 hp additional equipment.

PLANT FOR CEMENT WORKS.—The extensive improvements contemplated by the Phoenix Cement Company, Nazareth, Pa., have all been laid out by Dodge & Day, modernizing and contracting engineers, Nicetown, Philadelphia, Pa., and it is thought the work will be started in the near future. Most of the buildings will be enlarged, electrical transmission used throughout, and the entire plant thoroughly modernized in order to materially increase the output to keep pace with the growing demand for the Cement Company's product. This will necessitate the installation of considerable additional power equipment, as well as a 200-kw generator, tandem compound engine for generator, one 50 and one 75-hp motor, as well as a number of smaller motors; charging cars, turntable, coal and ashes conveyor, underfeed stokers, steam locomotive for hauling cars to and from the quarries; electric hoist, electric air compressor, blower and exhauster, air-cooling conveyors, elevators, automatic weighing machine, extension of the track system, etc.

A 1,500 KW. CURTIS FOR LONG ISLAND PLANT.—The Nassau Light and Power Company, which furnished power to Roslyn, Mineola, Hempstead, Seacliffe, Port Washington, Floral Park and several other Long Island villages, is to remove its plant from the first mentioned place to the water side at Glenwood, about four miles distant, which location will permit of a cheaper coal supply and better facilities for condensation. The rearrangement and enlargement of the condensing equipment has been entrusted to the Worthington branch of the International Steam Pump Company, 114 Liberty Street, New York. Two 400-kw Westinghouse turbines which are already installed at Roslyn will be transferred to the Glenwood plant, and additional equipment consisting of a 1,500-kw Curtis turbine has been contracted for. The transformers, switchboard, etc., have been ordered from the General Electric Company. Mr. C. O. Mailloux is acting as consulting engineer for the Nassau Company.

GOULD STORAGE BATTERY CONTRACTS.—The Gould Storage Battery Company, Astor Court Building, New York City, reports that among recent contracts closed by the company, are the following: Chambersburg, Greencastle and Wynesboro Railway, Waynesboro, Pa., two floating batteries, one of 242 cells, and one of 244 cells. Additional plates for Lexington Street Railway Company, Lexington, Ky., increasing the present output to 352 kw. Elder & Johnson, Dayton, Ohio, 60 cells of 400 amp. discharge, with Gould c.e.m.f. booster, for elevator regulation in Rebold Building. Bank of Montreal, Montreal, Can., 61 cells with a discharge of 960 amp., with motor driven end cell switch. Isolated and residential plants for C. C. Williams, Cohassett, Mass.; W. T. Smith, Elka, Nev.; United States Navy, Navy Yard, New York. Also six central battery system telephone plants at different places.

ALLIS-CHALMERS FOUNDRY PURCHASE.—The Bollmann-Wilson Company's foundry plant at Norwood, Cincinnati, has been sold to the Allis-Chalmers Company, through the Bullock Electric Manufacturing Company, of Ohio The foundry was established by Hoefinghoff & Lane at the request of the Bullock Company, which stated that it would take all the castings that the foundry would turn out. This purchase will give the Allis-Chalmers Company a modern equipped foundry, a shop with an area of 40,000 sq. ft. and six acres of land. The property lies across the street from the Bullock plant on Forest Avenue. It is the intention to improve the property and make additions. Besides the castings that will be needed for Bullock products there will be manufactured castings for Allis-Chalmers manufactures.

LIGHTING EQUIPMENT FOR SAN REGIS HOTEL.—More lighting equipment will be ordered shortly for installation in the new San Regis at Fifty-fifth Street and Fifth Avenue, New York. The machinery contracted for last year is capable of developing 1,000 kw. It consists of two 450-hp and the same number of 300-hp Harrisburg four-valve engines direct connected to Western Electric Company generators of 300-kw and 200 kw capacity respectively. The additional equipment will comprise a 300-kw lighting set. The contract will be awarded through Trowbridge & Livingston, 424 Fifth Avenue, the architects of the hotel.

THE INTERNATIONAL TELEPHONE MANUFACTURING CO., Chicago, have recently installed a complete inter-communicating system in the City Hall, Chicago. Each station is provided with an "International" desk set with long-distance transmitter, double pole receiver, and metallic jack plug-switch, enabling any one station being called directly from any of the others in the system. Any number of pair of instruments may be used simultaneously without interference.

TO ELECTRICALLY OPERATE OAXACA MINES.—Mexican advices state that application has been made to the fomento department by Don Manuel M. Mimiago y Camacho for a concession to utilize the waters of the Rio Atoyac in the State of Oaxaca, between the districts of Ocotlan and Ejutla. A large hydraulic plant is intended to be constructed. The current will be used for operating various mining plants in these districts.

EQUIPMENT FOR CANTON MANUFACTURING PLANT.—Parlin & Orindorff, the large agricultural implement manufacturers, of Canton, Ohio, are about to increase their power plant. An additional 500-hp equipment—one unit—will be installed.

General News.

THE TELEPHONE.

NEW DECATUR, ALA.—The franchises in this place of the Southern Bell Telephone Company, the American Telephone and Telegraph Company and the American Telephone and Telegraph Company of Alabama, have been revoked. The Morgan County Telephone Company is now in sole possession of the field. It is expected that the three first named companies will apply for an injunction against the city.

REDDING, CAL.—The Redding, Ingot & Wengler Telephone Company has been incorporated here with a capital stock of $10,000.

RED BLUFF, CAL.—The Balls Ferry Telephone Company is being organized by L. D. Cheeney, D. L. Gover and others. A line will be built from Balls Ferry to Anderson and Cottonwood.

SAN DIEGO, CAL.—The Home Telephone Company, which is to establish a local system, has filed articles of incorporation, the capital stock being $500,000. Among the incorporators are F. F. Graves and F. F. Boyce.

MORRIS, ILL.—The Stevens County Telephone Company has been reorganized with Mr. Berg as president.

TREMONT, ILL.—The Independent Telephone Exchange of Tremont has been incorporated by A. J. Davis, F. J. David and W. H. Ames. The capital stock is $20,000.

DUVALL, ILL.—The Okawa Township Telephone Company has been incorporated with a capital stock of $2500. The directors are G. L. McCullough, A. Roberts and others.

CHICAGO, ILL.—A rumor presages the organization of a telephone supply company to act in the interests of the Interstate Independent Telephone Association. Mr. Henry A. Barnhart, of Rochester, Ind., is quoted in a Chicago daily as saying such a company, with about $1,500,000 capital, is necessary to the life of the smaller independent telephone companies by reason of the absorption of supply houses.

WABASH, IND.—After wrangling for a year or more the city council has granted a franchise to the Central Union Telephone Company. The company's franchise expired over a year ago, and during this time the council and the company have been at sword's points while the company was doing business by sufferance. The officials of the Central Union say they propose making extensive improvements and will make a strong bid for a fair share of the business in Wabash and vicinity.

INDIANAPOLIS, IND.—The traffic committee of the Independent Telephone Association, which is composed of nearly all the long-distance independent telephone companies in the country, held a meeting in this city on April 2, and discussed plans for the betterment of long-distance service. Steps were taken toward the building of connecting links for the independent long-distance lines by agreeing to employ competent and expert telephone men to map out proper plans for perfecting the general scheme contemplated, and competent engineers to oversee the work. The members of this committee were appointed at a previous meeting and those attending the meeting were: F. S. Dickson, J. B. Hodge and B. W. Overley, of Cleveland, Ohio; C. H. Ledlie, R. M. Foster, St. Louis; M. R. Patton, Kansas City; C. L. Spain, Pittsburg, and S. P. Sheerin, Indianapolis.

SLOAN, IA.—The People's Rural Telephone Company is being formed here.

WEBSTER CITY, IA.—The Hamilton County Mutual Telephone Company has ordered a new switchboard, wire and other material, and will extend its system.

DES MOINES, IA.—The Hartley & Primghar Telephone Company, of O'Brien County, has been incorporated by W. N. Hulbert and others. The capital stock is $2000.

DES MOINES, IA.—The Elkhart Mutual Telephone Company has been incorporated with a capital stock of $10,000, the incorporators being O. F. Mathis, Albert Peterson, W. D. Cory, R. H. Ault and A. P. Besser.

ONOWA, IA.—The farmers of Fairview have decided to build an independent telephone line. The proposition of the Monona County Telephone Company to furnish service at $1.25 per month was not regarded by them favorably.

WHEATLAND, KAN.—The Wheatland Telephone Company has been organized to build a line from Wheatland to Conway.

PORTLAND, ME.—The Naples Telephone Company has been organized here to build lines in Naples, Bridgton, Casco and Raymond. The capital stock is $10,000.

DETROIT, MICH.—The Calhoun County Telephone Company has increased its capital stock from $150,000 to $250,000.

GRACEVILLE, MINN.—The Parnell Co-Operative Telephone Company has been granted a franchise in this place.

NEW ULM, MINN.—The Minnesota Central Telephone Company will build a line between this place and Sleepy Eye.

FARIBAULT, MINN.—Three telephone companies are seeking to do business in this city. The Northwestern (Bell) Company, which now controls the field, the Tri-State and a local company—the Rice County Telephone Company—are trying to secure franchises. Mr. A. R. Tracy, of Faribault, may give further information.

MERIDIAN, MISS.—The electrical committee has reported favorably on the movement to grant a franchise to an independent telephone company. The Cumberland Telephone Company also offered to grant any reasonable demands that would tend to lessen the friction which would be probable in case of two companies occupying the field.

NELSON, NEB.—The Nuckolls County Telephone Company will be organized here with a capital stock of $50,000.

MOCKSVILLE, N. C.—The Mocksville Telephone Company, of Mocksville, with a capital of $900 paid in and $10,000 authorized, has been chartered by L. G. Horn, of Mocksville, and others, to operate in five counties.

BINGHAMTON, N. Y.—The Treadwell Telephone Company has been incorporated to build a telephone line within the counties of Delaware and Otsego. The company now has about 100 miles of line and about 100 telephones in use.

SALEM, OHIO.—The Columbiana County Telephone Company is preparing to install new selective ringing telephones on its party lines in this district.

PAINESVILLE, OHIO.—The new telephone company organized at Perry, near here, has been organized as follows: President, W. W. Cook; secretary, F. E. Morrison; treasurer, E. M. Orcutt.

ALLIANCE, OHIO.—The Stark County Telephone Company has arranged a rate for interchange of service with the Bergholz Telephone Company and the Eastern Ohio Telephone Company. A rate will also be made with the Harrison County system.

ADAMSVILLE, OHIO.—The Adamsville Telephone Company has been organized with J. B. Rhodes, president; F. P. Winn, secretary, and S. M. Winn, manager. The company will install an exchange at Adamsville and will place contracts for material at once.

GIBSONBURG, OHIO.—The Seneca Telephone Company has been incorporated with a capital stock of $20,000 to build a line in Seneca and Sandusky counties. The incorporators are: N. B. Ervin, C. B. Synder, F. C. Hornung, F. W. Zorn and A. H. Miller.

LORAIN, OHIO.—The Ohio Telephone & Telegraph Company, which has been refused a franchise in Lorain, has made an arrangement with the Western Union Telegraph Company whereby it will use the latter's poles in Lorain and a small exchange will be fitted up.

CRESTLINE, OHIO.—The Crestline Telephone Company has elected J. Bapst, president; C. R. Callaghan, vice-president and general manager and F. A. Knapp, secretary. The company has 400 telephones in operation. It was decided to build new lines throughout the rural district in the vicinity of Crestline.

CINCINNATI, OHIO.—Mayor Mills has vetoed the ordinance granting a franchise to the Norwood Citizens Telephone Company. His reason for this action is that "It does not bind the company by bond or forfeiture to erect and operate a plant including an automatic exchange of reasonable capacity within a specified and reasonable time."

WEST MILLGROVE, OHIO.—A franchise has been granted to the West Millgrove Telephone Company, which will be incorporated at once with a capital stock of $2500. Construction material has already been ordered. The officers of the company are: President, Wilbur Rosendale; vice-president, J. P. DeWolfe; treasurer, C. D. Stearns; secretary, S. L. Ghaster.

CLEVELAND, OHIO.—The Federal Telephone Company has disposed of its interests in the Wood County Telephone Company, of Bowling Green, Ohio, to a company headed by H. A. Ashbrook, D. A. Yoder and J. S. Yoder, of Toledo. The company operates an exchange with 900 subscribers. It is the intention to reconstruct and extend the entire system and install a new board.

WOODSFIELD, OHIO.—The directors of the Woodsfield Telephone Company have chosen J. B. Rhoades as president; W. E. Mallory, vice-president; P. E. Fraley, secretary and treasurer, and F. C. Huth, general manager. The capital stock of the company was increased from $15,000 to $25,000. A number of extensions and improvements during the coming summer are contemplated.

CARNEY, OKLA.—The Carney Automatic Telephone Company has been organized here with a capital stock of $10,000. C. E. Wilcox, of Carney, is one of the incorporators.

QUAKERTOWN, PA.—The residents between Quakertown and Riegelsville along the line of the Quakertown & Eastern Railroad, are interested in the formation of a company to build a telephone line between the two towns. It is proposed to make a business arrangement with the Bell Company, which will make a charge of $3.60 per year per telephone.

TROY, S. C.—The Troy Telephone Company, of Greenwood County, S. C., has been commissioned with $800 capital. A. J. Davis and others are interested.

CHARLESTON, S. C.—The Edgemoor Telephone Company, of Chester County, S. C., has been chartered with $25,000 capital. H. B. Heath is president and J. D. Glass, secretary and treasurer.

ANDERSON, S. C.—The directors of the Anderson Telephone Company have decided to increase the capital from $10,000 to $30,000. This company owns several other lines in the county and has an agreement with the Bell Company as to long-distance service.

ABERDEEN, S. D.—The Dakota Central Telephone Company will extend its line from here to Mitchell.

LEWISBURG, TENN.—It is proposed to build a telephone line between Lewisburg and Yell. Mr. B. J. Coleman and J. K. Jobe are interested in the enterprise.

CORNERSVILLE, TENN.—A telephone company has been organized here to establish an exchange. A switchboard will be leased from the Cumberland Telephone Company, and the 25 subscribers will furnish the poles and wire and employ the operator.

ROCKINGHAM, VA.—The Rockingham Mutual Telephone Company has increased its capital stock $25,000.

SNOHOMISH, WASH.—The Skagit Farmers' Telephone Company has asked for a franchise in this place.

UTICA, WIS.—The Utica Telephone Company has been incorporated with a capital stock of $5000. The directors are G. Pickett, R. Mackie and others.

Electric Light and Power.

SAN FRANCISCO, CAL.—An official of the California Gas & Electric Corporation says that while the water supply and electric power plants owned by the South Yuba Water Co. and the Central California Electric Co. have not yet been taken over, the option held will probably be exercised within a month. This deal and the taking over of the Standard Electric Co. were arranged for at the same and the financing of the one depended upon the other.

YREKA, CAL.—The Little Shasta Power Company, recently incorporated, will be a sub-company of the Siskiyou Electric Power Company. Contracts have been signed by the Siskiyou Electric Power Company to deliver at Montague all of the power required by the Little Shasta Company. The Little Shasta Company has purchased the Terwilliger power line and will sell electrical energy for light and power throughout the Little Shasta Valley. Mr. W. H. Roberts, M. T. Jones and J. F. Reisser are among those interested in the enterprise.

SAN FRANCISCO, CAL.—The Northern California Power Company, which has its principal office in San Francisco, and plants in Shasta County, has commenced paying monthly dividends, the first one of five cents per share being payable March 25, 1904. At the recent annual meeting of this company H. H. Noble was re-elected president; Edward Whaley, secretary, and Antoine Borel & Co., treasurer. The gross earnings of the company for the year 1903 were $150,924.56, while those for the preceding eleven months amounted to $85,582.35. The earnings for February, 1903, were $14,221.84; 1902, $9,224.44; increase, $4,997.40. The financial report showed a surplus net earnings to March 1, 1904, of $97,111.23. At present 3634 hp is being developed at the Volta power station, and an additional 4000 hp installation is almost ready for operation at the Kilarc station on Cow Creek. With a few weeks of dry weather this plant will be ready to transmit current over the new line which connects with the main transmission line at Delamar. An additional 3-phase line will extend down Pitt River to Kennet. Redding, Red Bluff, Tehama and a number of other towns in a territory extending over three counties are supplied with light and power from this system. The annual report mentions a rather high figure as an estimate of the amount of power which might be obtained by developing the company's water rights on Pitt River.

SAN FRANCISCO, CAL.—The details of the contracts recently awarded by the San Francisco Gas & Electric Company for the increase of plant at Station "A" include one General Electric 11,000-volt, three-phase rotating-field engine-type generator, a Union Iron Works vertical engine and five Babcock & Wilcox boilers. The generator will be direct connected to the triple expansion engine. Two of the engines from Station "B" will be moved to Station "A," formerly the Independent Electric Light & Power Company's plant. This will become the principal generating station for the city and will have a capacity of 15,000 kw or more. The present plans contemplate an increase of 10,500 kw there. The changes will enable the company to dispense with steam engines at the old stations. The contract for the new boilers was placed through Charles C. Moore & Co., who will also move six Heine boilers from another station and remodel the boiler plant. All of the boilers in the station will be equipped with B. & W. marine oil furnaces and the Charles C. Moore & Co. oil fuel system will be installed. Two special Goubert oil heaters will be used. The five new B. & W. boilers will have forged steel drums and superheaters. The auxiliaries will also be supplied through Chas. C. Moore Co. Steam-driven pumps will be used throughout instead of extending the electric motor system for condensing apparatus, etc. Two compound duplex Snow feed pumps each having a capacity to feed a 16,000-hp boiler plant will be installed.

WASHINGTON, D. C.—A bill has passed the Senate, and is now in the hands of the District of Columbia Committee in the House, providing for the regulation of electric wiring in the District of Columbia.

WASHINGTON, D. C.—Bids will be received April 19 at the Bureau of Supplies and Accounts, Navy Department, Washington, for furnishing 176 electrical equipments for ammunition hoists, etc., for the U. S. Navy. Address H. T. B. Harris, Paymaster-Gen., U. S. N.

JOLIET, ILL.—Harlow A. Griswold and Attorney G. A. Munroe, of Chicago, are interested in the construction of a power plant about 10 miles below Joliet. About $1,000,000 will be expended.

CICERO, IND.—John Plain, of Cicero, has secured a franchise for an electric light plant.

JASPER, IND.—The town of Jasper is negotiating with the electric light company for the purchase of its plant here. An appraisement has been made and a sale is quite probable. New machinery and other electrical apparatus will be added to the plant in case of sale.

VINCENNES, IND.—The Vincennes Light & Power Company, incorporated under the laws of Michigan, has been admitted to Indiana. The company will invest $200,000 in this city in the purchase and taking over the property of the Citizens' Gas Light Company and Vincennes Electric Light & Power Company and will hereafter operate the same. Edward M. Deane, D. W. Smith, H. T. Heald and E. M. Deane, all of Grand Rapids, are the stockholders.

OGDEN, IA.—The Northwestern Equipment Co., of Minneapolis, Minn., has secured the contract for constructing an electric light plant for $9000.

LOWELL, KAN.—The Spring River Power Co., of Lowell, has been incorporated, with a capital of $450,000, by Sam'l Brown, of Chicago; T. F. Garver, J. B. Larimer and others, of Topeka, to furnish electric power.

LOUISVILLE, KY.—An ordinance is before the city council requiring that all electric wires in the city be placed underground. A similar bill was presented a few weeks ago but it was withdrawn on account of some imperfections.

PRESQUE ISLE, ME.—The electric lighting and heating station owned by the Presque Isle Electric Light Company was destroyed by fire March 25.

PORTLAND, ME.—Electric wires on Congress street in this city are to be placed underground.

BALTIMORE, MD.—A bill has been reported to the Legislature at Annapolis requiring that all electrical contractors and workers shall be licensed, and providing for a Board of Managers.

ANNAPOLIS, MD.—A bill has been introduced in the Legislature providing that no telephone company shall engage in the electric lighting business in the City of Baltimore. The bill is said to be aimed at the Maryland Telephone Company, which recently applied for a franchise to conduct electric lighting in that city.

CAMBRIDGE, MASS.—The Massachusetts Board of Gas and Electric Light Commissioners has authorized the Cambridge Electric Light Company to issue $100,000 additional capital stock to pay for extensions to the plant.

BOSTON, MASS.—At the annual meeting of the Electric Lighting Engineers of New England, held at the Parker House on March 16, the following officers were elected for the ensuing year: President, J. W. Cowles, Boston; vice-president, F. S. Richardson, No. Adams; secretary and treasurer, C. R. Brown, Boston; directors, W. H. Coughlin, Worcester; F. C. Smith, Somerville; W. C. Woodward, Providence; W. E. Holmes, Newton; S. F. Smith, Salem; E. H. Mather, Portland.

GRAND RAPIDS, MICH.—The entire municipal lighting system in this city was put out of service a few days ago by the high water in the river extinguishing the fires in the boilers at the plant. The city was in darkness for the time being.

ST. LOUIS, MO.—A contract has been let for the erection of a power house between the observation wheel and the ice plant, just west of the power plant of Machinery Hall, at the World's Fair. This plant will supply the power for the wheel and the ice plant. The wheel will be illuminated by 6000 electric lamps. P. D. C. Ball, who is also installing the ice plant, is erecting the power house.

RENO, NEV.—The Reno Power, Light & Water Company is incorporated, with a capital of $1,000,000, by P. L. Flannigan and W. H. Patterson, both of Reno, and others.

DELHI, N. Y.—The question of issuing $20,000 bonds for a municipal lighting plant is under consideration here.

ROCHESTER, N. Y.—It is reported that the Clark syndicate, which controls the Rochester Railway Company, is negotiating for the purchase of the Rochester Gas & Electric Company. The railway company, it is stated, has not sufficient electric power. It now obtains 1000-hp. from the electric company. The latter concern owns extensive water rights, many of which have not been developed and which could be utilized for the generation of a large amount of power.

HILLBURN, N. Y.—A new plant is being built for the Rockland Electric Company at Hillburn, N. Y., to use the new high-powered Westinghouse gas engines with producer gas, using the Loomis-Pettibone system. This producer plant is located in a separate building, and supplies gas to the Ramapo Iron Works and the Ramapo Foundry Company for heating and metallurgical purposes, as well as power gas to the generating station. The electrical system will supply current to local industries, as well as light the Ramapo Valley some 14 miles in extent. The equipment aggregates 1200-hp power, employing 350 single crank engines of the double acting type, and a small vertical single acting engine for the exciter. Each main engine is direct connected to Westinghouse polyphase generators, arranged for parallel operation.

NEW YORK, N. Y.—The following are among the recent additions to the membership of the National Electric Light Association: Active: Colorado, Boulder, The Boulder Electric Light and Power Company; Michigan, Cheboygan, Cheboygan Electric Light and Power Company; Minnesota, Montevideo, Montevideo Electric Light and Power Company; Mississippi, Indianola, Indianola Light, Ice and Coal Company; Missouri, St. Joseph, St. Joseph Railway, Light, Heat and Power Company; Ohio, Bellevue, The Bellevue Light and Power Company; Ohio, Massillon, Massillon Light, Heat and Power Company; South Carolina, Darlington, Darlington Light and Water Company; Texas, Beaumont, Beaumont Ice, Light and Refrigerator Company. Associate: New York City, J. J. Kennedy, Consulting Engineer; New York City, The Cassier Magazine Company; Philadelphia, Pa., James H. Dawes, Supt. of Construction Nat'l Gas and Construction Company.

JONESBORO, N. C.—A. F. Spencer, of Sanford, N. C., has been granted a franchise to supply light, heat and power in this place. He has also secured the contract to light the streets with arc and incandescent lights for five years.

DAYTON, OHIO.—Mayor Snyder has vetoed the ordinance granting a franchise to the Dayton Electric Light Company. The reasons for the Mayor's actions are, it is stated, that the company has not kept its contract with the city as to prices for commercial lighting and power; that the ordinance does not impose underground wire conditions, besides other reasons.

EL PASO, TEX.—The Southern Pacific Company will install an electric power plant here for the operation of the machinery of its railroad shops.

BRYAN, TEX.—The city council of Bryan has granted a franchise to H. B. Dorsey, of this place, for the erection and operation of an electric light and power plant here.

SOUR LAKE, TEX.—Two applications for franchises to establish an electric light plant and a water works system at Sour Lake are pending before the city council. One application is by Messrs. Sloan, Maxwell and McVeigh, of Sour Lake, and the other by Mrs. C. W. Allen, of Houston.

SALT LAKE CITY, UTAH.—Articles of incorporation of the Standard Power Company, with a capital stock of $1,000,000, have been filed with the Secretary of State. The purpose of the company is to establish a power plant at a cost estimated at $500,000 on the Sevier River in the southern portion of the State. It will have a capacity of about 5000 horse-power, and work on the project will be commenced early during the present season.

WAUWATOSA, WIS.—The action of the city administration last fall in giving away electric street railway and lighting franchises, in opposition to a petition of voters asking for a referendum vote, was the cause of an earnestly fought contest at the recent municipal election resulting in victory for the independent citizens. A proposition for a twenty-year franchise for city lighting by a Milwaukee company was defeated by a large majority.

The Electric Railway.

BIRMINGHAM, ALA.—The Birmingham Railway, Light and Power Company has voted to issue $10,000,000 bonds for refunding and for improving the system.

WILMINGTON, DEL.—The Wilmington New Castle & Southern Railway Company has been organized with the following officers: Henry L. Evans, president; Willard Saulsbury, vice-president; Chauncey P. Holcomb, secretary; Francis R. Morrison, treasurer; Henry L. Evans, Harry A. Richadson, Peter J. Ford, Willard Saulsbury, T. Bayard Heisel, Harry J. Stoeckle and Francis Kelley, directors. The capital stock of the company is $300,000. The new company is the result of a merger of the Wilmington & New Castle and the New Castle & Delaware City companies. The officers of the new company were authorized to issue $650.000 bonds, of which $300,000 are to be used in taking up bonds to the same value of the constituent companies, and the proceeds of the remainder are to be utilized for improvements and extensions.

ATLANTA, GA.—A charter for the Piedmont Electric Railway Company to extend from Atlanta to Roswell, Alpharetta and Cumming, Ga., has been granted to E. S. Brazelton, of Birmingham, Ala.; Charles Kingsbery, E. C. Atkins, T. J. Hightower, C. W. Hunnicutt, John T. Stocks, H. L. Hunter, B. F. Curtis, Charles R. Maddox, R. E. Bondurant, J. A. Tiler and John Burnett, of Atlanta.

CHICAGO, ILL.—The stockholders of the Lake Street Elevated Railroad have voted to change the name to the Chicago & Oak Park Elevated Railroad Company.

JOLIET, ILL.—The Joliet, Newark & Southwestern Railroad Company, of Newark, has been incorporated, with a capital stock of $10,000. The incorporators are: H. K. Thunemann, O. L. Miller, A. M. Sweetland and others.

CHICAGO, ILL.—The South Side Elevated Railroad Company stockholders voted unanimously to increase the capital stock of that company by $7,226,700 to a total issue of $17,550,500, at a special meeting on April 7. The proceeds of this new issue will be used to defray the cost of the proposed extensions to Englewood and to the Stock Yards, and for the construction of a third track for express service between 12th Street and 43d Street.

BLOOMINGTON, ILL.—The Springfield, Lincoln, Bloomington, Pekin & Peoria Electric Railway, incorporated recently, with a capital stock of $50,000, is to be organized here on April 12. The plan of the company is to build an electric railway from Bloomington to Lincoln and thence to Springfield, and from Peoria to Lincoln, with a cross line from Morton to Pekin. F. H. Funk and F. W. Aldrich, of Bloomington, are among those interested.

. CRAWFORDSVILLE, IND.—It is stated that the Consolidated Traction Company will erect a power house at once. Edward Hawkins, Indianapolis, is president.

NEW ALBANY, IND.—The directors of the Highland (Electric) Railroad have ordered that this road, which ceased operations three months ago, be offered for sale at auction.

BEDFORD, IND.—The Bedford Street & Interurban Railway Company has organized as follows: V. V. Williams, president; W. N. Mathews, vice-president; E. B. Thornton, treasurer; W. R. Martin, secretary.

EVANSVILLE, IND.—A. L. Rich, of Cincinnati, and H. W. Richardson and J. E. Bohanon, of Louisville, who recently purchased the Henderson (Ky.) City Railway system for $250.000, announce that they will at once extend the road a distance of 12 miles to Evansville, and establish an interurban system between the two cities. The Evansville & Henderson Traction Company, capitalized at $10,000, has filed articles of incorporation. The directors are: H. E. Randall, C. C. Tennis, J. W. Prietiard and C. H. Baltin.

TERRE HAUTE, IND.—Contracts will soon be let for the construction of the new power house of the Terre Haute Electric Company. Contracts for the machinery for the plant were let early in the year. The General Electric Company will furnish all of the electrical machinery. The boilers will be furnished by the Aultman & Taylor Company.

INDIANAPOLIS, IND.—The Union City, Winchester & Muncie Traction Company has filed articles of incorporation. The company is capitalized at $10,000, but reserves the privilege to increase the capital to $2,000,000. The company proposes to build a line from Union City to Muncie. Dr. J. E. Lowes, J. E. Feight, Theodore Shockney and W. B. Gebhart are the incorporators.

LEBANON, IND.—At the annual meeting of the stockholders of the Indianapolis & Northwestern Traction Company the following officers were elected: George Townsend, president; Philip L. Saltonstall, vice-president; Chauncey Eldridge, treasurer; Winthrop Smith, secretary; George Townsend, W. S. Reed, S. R. Anthony, Thos. Pettigrew, Philip Saltonstall, Chauncey Eldridge and Winthrop Smith, directors.

IOWA CITY, IA.—The city council has voted a franchise to the Iowa City, Davenport & Muscatine Electric Railroad. A special election will be held at an early date for the purpose of ratifying this action of the council.

COLUMBIA, KY.—W. K. Azbill, of Columbia, says the plan to build an electric railway between Columbia and Lebanon, a distance of 46 miles, is in the primary stages.

SPRINGFIELD, MASS.—The Springfield & Eastern Railway Company, operating in and about Palmer, has decided to apply for a grant of location from Ludlow into Springfield.

NEWBURYPORT, MASS.—The Citizens' Electric Street Railway Company lost about $60,000 March 28, by the burning of its car houses on Merrimac Street and some twenty-eight cars and plows. Seven cars were in use on the street, and these are all that were saved.

FITCHBURG, MASS.—The directors of the North Leominster, Shirley & Ayer Street Railway have voted to begin at once the construction of a line from North Leominster to Ayer. W. W. Sargent, superintendent of the Fitchburg & Leominster Street Railway, is to have general charge of the new line, which makes connection at North Leominster with the Fitchburg & Leominster. It is the intention to build on to Lowell eventually.

NEGAUNEE, MICH.—Among the improvements contemplated by the Negaunee & Ishpeming Street Railway & Electric Co. is the enlargement of the electric light plant, for which plans are now being prepared. An order will soon be placed for the new machinery. The capacity will be increased from 5000 to 10,000 incandescent lights. H. F. Pearce, Negaunee, is manager.

ST. LOUIS, MO.—Mayor H. L. Ponder, of Walnut Ridge, Ark., and S. C. Dowell, president of the Lawrence County bank of that city, were in St. Louis recently to complete arrangements for the organization of the Hoxie and Walnut Ridge Electric Light, Power and Transit Company, a venture in which some prominent St. Louisans are interested. The company is capitalized at $65,000, and its primary purpose is the installation of an electric railway between Hoxie and Walnut Ridge. These towns are connected now by a mule car line.

LINCOLN, NEB.—The property of the Lincoln Traction Company will be resold, Judge Holmes having decided that the company's bid of $1,025,000 for its own property did not comply with the terms.

RENO, NEV.—The franchise and property of the Reno Traction Company has changed hands by purchase, and S. C. Griffith, president of the company, announced that work on the prospective road will be commenced at once.

ROCHESTER, N. Y.—The Rochester, Scottsville & Caledonia Railway Company has been organized.

WELLSVILLE, N. Y.—Interest has again been revived in the proposed electric railway from Wellsville to Bolivar. Oak Duke, of Wellsville, is interested.

AMITYVILLE, N. Y.—The Huntington & Amityville Traction Company has accepted the franchise granted it here, and posted a bond of $7500 to insure compliance with the terms of the grant.

ADDISON, N. Y.—Attorney Seibert, of Coudersport, is interested in the proposed electric railway from Addison to Olean, connecting at the latter place with the proposed line to Bolivar. The distance from Addison to Olean by this route is about 72 miles.

CINCINNATI, OHIO.—The statement is made here that the Westinghouse Company is negotiating for the equipment of the Cincinnati, Dayton & Toledo Traction Company with single-phase motors.

CLEVELAND, OHIO.—On April 2 more than 100 of the motormen and conductors of the Cleveland & Southwestern Traction Company went on strike because of the refusal of the company to remove General Manager Nicholls, who is charged by the men with making rules unfair to them.

TOLEDO, OHIO.—The Toledo Railways & Light Company is building an addition to the boiler house at its main power station, and has placed a contract with the Ricard Boiler Company, of Toledo, for four 650 hp water-tube boilers, to be equipped with stokers.

BOWLING GREEN, OHIO.—The Lake Erie, Bowling Green and Napoleon Railway Company has filed a mortgage for $1,000,000 to the Union Trust Company, of Detroit. The money will be used in extending the road eastward to Port Clinton and westward to Napoleon. Work on the extensions is to start at once.

PITTSBURG, PA.—The McKeesport & Clairton Connecting Railway Company has accepted the ordinance granting the company a right of way in McKeesport.

HARRISBURG, PA.—The State Department has issued a charter to the Allen Street Railway Company, capital $30,000, to build a 5-mile line between Nazareth and Bath, Pa. The directors are: Thomas D. Danner, of Easton, president; Peter Raub, J. R. Ballentine, H. G. Seip, Edward McCaffrey, C. F. Seip, all of Easton.

HARRISBURG, PA.—A charter has been issued by the State Department to the Grove City Street Railway Company, capital $18,000, to build a 3-mile line in Grove City. The officers are: Edward Austin, president; R. N. Washabaugh, Arthur H. Springer, Samuel G. Bailey, J. H. Mehring, A. B. Stone, Vernon Hazard, directors.

BRISTOL, VA.—Plans are being discussed for building an electric railway from Cleveland, Va., to Lebanon, and thence through Washington County to Bristol.

RICHMOND, VA.—The street railway company here has announced that after April 15 it will enforce the law which permits conductors to separate white and negro passengers. Any persons failing or refusing to observe the orders of the conductor will be liable to a fine of $25, and may also be ejected from the car for such refusal.

NORFOLK, VA.—The Norfolk, Portsmouth & Newport News Company in which has been merged the Norfolk Railway & Light Company, the Berkley Street Railway Company and other like concerns, it is stated, is about to be dissolved. It is reported that the dissolution is due to the fact that after a trial the combined railways did not find the arrangement profitable and all concerned felt that by the individual operation of the roads larger dividends could be paid to the stockholders.

WELLSBURG, W. VA.—H. G. Lazear, of Wellsburg, has been granted a franchise for the construction of an electric railway from Wellsburg to Bethany.

WATERTOWN, WIS.—The City Council has passed the franchise giving the Oconomowoc & Watertown Heat, Light & Power Company permission to build an interurban electric railway through the city.

PORT ARTHUR, ONT.—The Electric Railway & Light Commissioners have recommended the installation of a storage battery plant in the power house.

SARNIA, ONT.—The St. Clair Tunnel Company has had engineers on the ground making estimates on the cost of installing a system of electric power for operating the trains through the tunnel.

NEW INDUSTRIAL COMPANIES.

THE AUTOMATIC SCENIC PHONOGRAPH COMPANY has been incorporated in New York with a capital stock of $5000. The directors are: C. C. Reinhardt, Christopher Peel and C. T. Willard.

THE CENTURY ELECTRIC CORPORATION, of San Francisco, Cal., has been formed by F. M. Greenwood, C. M. Wood, E. F. Weihe, L. D. Hitzeroth and H. S. Tittle, with a capital stock of $250,000.

THE TALMONT ELECTRIC ENGINEERING COMPANY has been incorporated in New York with a capital stock of $5000. The directors are: Adolph Talmont, G. D. Roedelsperger and M. J. Hornthal.

THE McCLEARY ELECTRIC COMPANY has been incorporated at Detroit, Mich., with a capital stock of $10,000, of which $6500 has been paid by a transfer of the McCleary & Colquitt Company's stock and fixtures.

THE ELECTRIC SUPPLY AND MAINTENANCE COMPANY, of Troy, N. Y., has elected officers as follows: President, A. V. Phillips; vice-president, A. S. Crable; secretary, Henry Schneider; treasurer, H. G. Hammett.

THE BISON MOTOR COMPANY, of Buffalo, N. Y., has been incorporated to manufacture motors, engines, etc., the capital stock being $25,000. The incorporators are: F. I. Alliger, Tonawanda; F. Wende, Wm. A. Lutz, Buffalo.

THE RANDALL MOTOR CAR COMPANY, of Ft. Wayne, Ind., has incorporated capitalized at $10,000. The company's manufacturing plant and principal office will be in Ft. Wayne. F. P. Randall, A. L. Randall and Louis Olmhaus are directors.

THE HEAT, LIGHT AND POWER IMPROVEMENT COMPANY OF AMERICA has been incorporated in New York City with a capital stock of $600,000. The incorporators are James P. Bowery, Andrew Ritchie and Charles Eldridge, of New York City.

THE SOLOMON RIVER DITCH COMPANY has been organized at Portland, Me., for the purpose of conducting a general electrical power, light and heat business. The capital stock is $1,000,000, of which nothing has been paid in. George F. Gould, of Portland, has been elected president.

LEGAL.

INDEPENDENT TELEPHONES IN CINCINNATI.—Judge Nipper in the Probate Court at Cincinnati, has decided that independent telephone companies have the right to use the streets of Cincinnati. This right, he stated, was granted by the statutes of Ohio, and all the court was required to do was to decide the manner in which the streets shall be so occupied. The companies concerned are the Cincinnati Telephone Company, the Queen City Telephone Company, the Fitzsimmons Company and the Interstate Company.

TELEPHONE POLES IN HIGHWAY.—The New York Supreme Court, Appellate Division, Third Department in the case of Gray et al, versus York State Telephone Company, has held that (1) The erection of telephone poles in a rural public highway is an added burden to the owners of the adjoining land, who own the fee in the highway, the right to impose which must be obtained either by consent of the owners or by condemnation proceedings. (2) The owners of the fee of a highway may prevent the erection of telephone lines thereon for permanent use by injunction.

ST. LOUIS ELECTRIC LIGHT CONSOLIDATION.—Morgan Jones, of Denver, Col., has brought suit in the United States Circuit Court to set aside the consolidation of the Missouri Electric Light & Power Company, the Union Electric Light & Power Company and the Citizens' Electric Light & Power Company, of St. Louis. These companies are constituents of the North American Company, of New York. Mr. Jones alleges that the merger was effected by fraud and asks for an injunction to restrain the officers of the consolidated companies from a further use of funds and for the appointment of a receiver to take charge of the Missouri-Edison Company's property.

HOUSE MOVING AND TELEPHONE LINES.—The Supreme Court of North Dakota has decided an interesting and novel case, on appeal, as follows: 1. A person licensed to move houses in the city of Grand Forks is legally liable for damages done by him while moving a house, such damage being done to the wires and property of a telephone company, duly authorized by ordinance to establish a telephone system in said city and maintained therein. 2. By the passage of such ordinance, which gave the city benefits, and its acceptance by the company, and its expenditures thereunder, a contractual relation was created between the company and the city, which became a vested right that could not be impaired by subsequent action of the city directly or indirectly annulling it for purposes not public, and for purposes of a personal or private nature. 3. The use of a street for moving houses is an extraordinary use thereof. Such use may be permitted, but not so as to destroy the use of the street for travel or necessary public purposes, and cannot be legally done in destruction or impairment of vested rights. The building moved was 7 feet higher than the highest telephone circuit in question.

FORFEITURE OF TELEPHONE GUARANTEE.—In the Supreme Court of Michigan in the suit of the City of Detroit vs. the People's Telephone Co., of Detroit, the decision of the lower court forfeiting $1529 with interest was affirmed last March on the ground that where a telephone company pursuant to its franchise had deposited with a city a sum of money as guarantee that its system should be in operation within a certain time, to be forfeited in case of failure, the entire sum was forfeiture by failure and not merely such portion as would compensate the city for the damages suffered. Upon the trial the evidence showed that the company had commenced the construction of the plant within the required time, and had procured 3500 bona fide subscribers, as required. But the evidence of the defendant also showed that it had not operated the system put in by it, with the exception of some 30 telephones placed in an interior exchange at the Parke, Davis & Co. plant, and also that they were not in position at the time of the trial to supply any more patrons with telephones. The contention of the defendant was that for any breach of the conditions imposed by section 10 the city was only entitled to such compensation and damages as it could be shown that it suffered by reason of the default of the telephone company, and that, as no such damages were shown, the defendant was entitled to offset the $5000 and interest, and recover the balance above plaintiff's claim. The circuit judge held otherwise, and directed a verdict for the plaintiff for the full amount claimed.

OBITUARY.

MARTIN D. WOOD, who was for 35 years local manager of the Western Union Telegraph Company at Kansas City, Mo., died there April 6, aged 60 years. He was a veteran of the civil war.

MR. THEODORE E. THEBERATH, who was formerly engineer for the San Francisco District agency of the Stanley Electric Mfg. Company, died at his home in San Francisco, March 29, after a brief illness. He was a native of New Jersey and 40 years of age. Mr. Theberath of late years was in the employ of the California Gas & Electric Corporation, his last work being as superintendent of the construction of the DeSabla water power electric plant. The funeral took place on April 1. His wife survives him.

MR. R. WELLS.—A special telegram from Glens Falls, N. Y., of April 9, says: Raymond Wells, a civil engineer in the employ of the Hudson River Water Power Company, received a shock from an electric wire carrying 30,000 volts at the Spier Falls power house of the company late yesterday, and was so badly injured that he died from the effects at midnight. He was on the roof of the power house making some measurements, and accidentally touched with a steel rod he was carrying a wire heavily charged with electricity.

MR. J. L. WEEKS, general manager of the American Steam Gauge and Valve Co., Boston, Mass., died in that city on April 2 after an operation for appendicitis the day previous. Mr. Weeks was well known in the electrical and steam engineering fields throughout the country, and it was principally due to his energetic and persistent efforts that the business of the company he managed was brought to the prominent place it occupies amongst steam specialty manufacturers. The remains were taken to Chicago for burial. Mr. Weeks was only 37 years of age.

MR. CHARLES WATSON.—We regret to note the death of Mr. Charles Watson, a gas pioneer, more lately identified also with electric lighting, etc. He died at Camden, N. J., March 30, aged 73. He was born at Portland, Me. He was one of the organizers of the Camden Gas Light Company in 1854, and served as its secretary and treasurer for over 25 years. He resigned from its service when the company was absorbed by the South Jersey Gas, Electric and Traction Company. At the time of his death he was a director in the Public Service Corporation of New Jersey, and was actively connected with many other important financial and commercial enterprises of South New Jersey. Among the pallbearers were John J. Burleigh and Judge Armstrong, of the National Electric Light Association.

MR. J. W. HINKLEY.—Mr. James W. Hinkley, president of the United States Casualty Company of New York, and for a number of years prominent in Democratic State politics, died suddenly on April 11 at Poughkeepsie, N. Y. Mr. Hinkley had not been in good health for a year. He was born in 1850 at Port Jackson, Clinton County, N. Y., and was educated at the Smith and Converse Academy and at the West Point Military Academy. He went to Poughkeepsie and became owner of *The News Press*. Later he purchased and assumed editorial control of *The New York Daily Graphic*, which brought him in contact with prominent men of each of the political parties, but particularly with the leaders of the Democratic party in this State. Mr. Hinkley was very successful in business and quite active in electrical affairs. He was president of the Poughkeepsie City and Wappingers Falls Electrical Railway Company, president of the Walker Electric Company, of Cleveland, Ohio; a director of the Poughkeepsie Trust Company, and of several New York banks. Mr. Hinkley is survived by his wife and eleven children, one of whom is Capt. J. W. Hinkley, Jr., stationed at Fort Washington, Md.

PERSONAL.

MR. DWIGHT C. CLOUGH has been appointed city electrician of Long Beach, Cal.

MR. C. C. CRAFTS, of the New York export department of the Westinghouse Electric interests, has returned from a four weeks' trip to Mexico.

MR. F. D. PHILLIPS, formerly with the Electric Appliance Company, is now identified with the Crescent Company, of Chicago, of which he has recently been elected vice-president.

MR. F. A. PICKERNELL, chief engineer of the American Telephone & Telegraph Company, has been in the West on a tour of inspection. He was in Salt Lake City at last reports.

MR. W. MURRAY CRANE, ex-Governor of Massachusetts, and largely interested in the Bell telephone system, and Clarence H. Mackay, president of the Commercial Cable Company, have been elected directors of the Manhattan Trust Company.

MR. W. J. HAMMER.—The handbook on radium by Mr. W. J. Hammer is one of the "Best Fifty" books voted as desirable this year for a village library, in connection with the list submitted to librarians of New York by the New York State Library.

MR. CHARLES MAUTNER, well known in electrical circles in and around New York, has assumed the general management of the newly organized Switchboard Company, of New York, which will manufacture a full line of switches, switchboards and panel boards.

CLARK & MACMULLEN, INC., electrical and consulting electrical engineers, have moved their Pittsburg office to the Farmers' Bank Building, that city.

MR. W. S. ACCLES, European representative of the Miles-Bement-Pond Company, is now on a short visit to this side.

MR. EDMUND ALO, the Swiss hydraulic engineer expert who was recently commissioned by the New Zealand government to ascertain the possibilities of local rivers for generating electric current, is to take up his abode permanently in the Antipodes, as consulting engineer in electricity and hydraulics.

MR. W. F. WARDEN, president and general manager of the Burt Manufacturing Company, sailed for Europe in the Celtic April 15, where he will visit agents of his company in England, France, Germany, Belgium, Norway, Sweden, Denmark, Russia, and, if time permits, in Switzerland, Greece and Spain.

MANAGER WICKHAM, of the Hongkong (China) Electric Company, is at present in the United States. He will visit some of the principal power stations and electric manufacturing plants in the East and Middle West. He is now in Pittsburg, but will be in New York early next week at the Hoffman House.

MR. LE ROY W. STANTON, the well-known electrical engineer, of Cleveland, Ohio, will read a paper on "Modern Telephone Engineering" before the International Electrical Congress, which will be held at St. Louis next September. He has just opened a branch office in Chicago, in the Monadnock Building, in charge of Mr. Byron B. Carter.

MR. ROBERT L. WARNER has been relieved of the detail duties of the management in connection with the Boston office of the Westinghouse Electric and Mfg. Co., and appointed New England manager. He will have general charge for that section, and Mr. D. E. Manson will assist him, with the position of manager of the Boston office.

MR. RALPH G. ARNOLD, treasurer of the Arnold Electric Power Station Company, was married recently at Brooklyn, N. Y., to Miss Hazel McLain. The wedding was at the house of the bride, those present being members of the immediate families. After a short trip in the East, Mr. Arnold and his bride will take up their residence in Chicago.

PROF. A. G. BELL has decided to give a public exhibition of his famous tetrahedron kite, until now seen by no one but the men who helped him to construct it and to fly it at Cape Breton Island over a year ago. The exhibition is to be given before the National Geographical Society at an open-air meeting and exposition, to be held on Saturday, April 30, at Washington.

MR. JOHN D. HIBBARD and Mr. Paul Flatchford have been re-elected as president and secretary respectively of the Chicago Metal Trades Association. This association of employers has done much to improve a very troublesome labor field, and these two men have won the respect and esteem of the labor union officers while bringing about more harmonious relations with their employees.

MR. CHARLES F. FOSTER has been appointed chief operating engineer of the power plant of the Louisiana Purchase Exposition. Mr. Foster was the chief mechanical engineer at the World's Columbian Exposition in 1893. He is vice-president of the National Supply Company and a member of the American Society of Mechanical Engineers, the St. Louis Engineers' Club and the Western Society of Engineers.

MR. E. R. CARICHOFF, formerly chief engineer of the Otis Elevator Company, and now with the International Steam Pump Company, is installing for that company a very complete lighting and power distribution plant at the Harrison Works. The generating plant is of 1000-kw. capacity, with space reserved for future enlargement. All tools will be driven by electric power, many having individual motors.

MR. J. D. ROCKEFELLER has made a contract with the Cleveland and Southwestern Traction Company for delivering by freight trolley to his summer home at Forest Hill, near Cleveland, a large amount of fine washed gravel for making roadways and walks in his private park. He bought a gravel bank at Wellington, 45 miles from Cleveland, and the material will be screened and washed and delivered to Forest Hill in bags at night.

MISS SARAH FARMER, daughter of the late Prof. Moses G. Farmer, has just sustained a severe and irreparable loss in the destruction by fire of the old homestead at Greenacre, on the Piscataqua River, near Eliot, Me. The house was full of relics of the family and of her father's electrical inventions and studies, and these of course can never be replaced. The American Institute of Electrical Engineers had a meeting there in the summer of 1897, and enjoyed generous hospitality at Miss Farmer's hands.

THE GENERAL ELECTRIC ENGINEERING SOCIETY, of Lynn, Mass., recently held its annual election of officers with the following result: President, C. M. Green; vice-president, A. E. Hayes; secretary, G. E. Sanford; treasurer, F. D. Bartlett, executive committee, E. E. Boyer; technical committee, R. Fleming, chairman, G. H. Pickney and J. M. Davis; membership committee, H. J. Arnold, chairman, C. A. Stanley, J. Walsh, R. W. Douglas and E. M. E. Humphries. On April 22 Mr. D. B. Rushmore will speak on "Alternator Design."

MR. G. MARCONI.—A dispatch from Rome, Italy, says: People who think of Marconi only as the inventor of the wireless telegraph do not know the scope of his talents. He has a fine tenor voice and has been chosen by the Abbe Perosi, the leader of the Sistine chapel-masters, to sing one of the principal parts in his new oratorio, "The Universal Judgment." The Pope recently had an interview with this future interpreter of his favorite contemporary musical authority. Marconi offered even to sing for him, but his Holiness said he did not wish to take advantage of the latter's willingness to oblige. He asked Marconi in what church he would sing, and when the latter replied that he would not sing in a church, but at the Costanza, the Pope sighed a little, as if he found the bounds of the Vatican very narrow.

SIR OLIVER LODGE has ideas in religion as well as in electricity. A controversy over the Sacred Scriptures has arisen recently in England, in which he takes a hand, advocating a reinterpretation of Christian doctrine. He regards the "doctrine of atonement in its concrete form as a survival from barbarous times," repudiating the belief in "an angry God, appeased by the violent death of Christ," and maintaining that human nature now is "rising to the conviction that we are part of nature and so part of God. In this sense the union of divinity is what science some day will tell us is the inner meaning of the redemption of man."

MR. ARTHUR WILLIAMS, general inspector of the New York Edison Company, receives an extraordinary tribute at the hands of the *New York Commercial*, in its rather vigorous discussion of rates and charges. It says that it is almost worth being overcharged to gain the privilege and interview with this "highly gifted conversationalist" and adds: "What salary the company pays Mr. Williams is unknown; but whatever it be, it is not one-half of what he earns. To have such a perennial fount of the milk of human kindness, qualified with just a dash of blarney, welling forth in the complaint department of an electric light company, calming the perturbed spirit of its exasperated, not to say murderously-inclined patrons with honeyed gush is worth a deal of money to the corporation." It might be noted that Mr. Williams's topic was the Thomson wattmeter, whose merits the daily newspaper man was not quite ready to admit.

Trade Notes.

CHANGE OF ADDRESS.—The DeForest Wireless Telegraph Company has moved its headquarters from 100 Broadway to 42 Broadway, New York.

THE BUFFALO BOX FACTORY, Buffalo, N. Y., which was recently destroyed by fire, will be rebuilt and equipped with an electric power plant.

CARLETON-CHASE ELECTRIC CO., New York, has moved to 37 Warren Street, where all orders will be promptly filled and business carried on as usual in spite of the recent fire in its old quarters.

LARGE METER.—The Duncan Meter Company, of Lafayette, Ind., is making a meter for the new Chicago postoffice, which, it is said, will be the largest meter ever built. It will register 42,000 16-cp incandescent lights.

THE CRESCENT COMPANY, Chicago, has found it necessary to equip its factory with electric drive in order to take care of its constantly increasing orders for the Crescent soldering sticks and Crescent soldering paste.

THE MAXFIELD-FRANCKE CO., representing the Francke four-ported engine, has removed its offices to the Electrical Exchange Building, 136 Liberty street, New York City, where it will be glad to receive visitors and inquiries.

THE ELECTRIC APPLIANCE COMPANY, Chicago, reports that its sales on Packard lamps during the winter just past have far exceeded all previous records. This, the company states, is no phenomenon, but merely a result of the maintained efficiency of the high-class Packard product.

NUERNBERG CARBONS.—We are advised that after careful and exhaustive tests, the Louisiana Purchase Exposition Company of St. Louis has given a contract to Mr. Hugo Reisinger, of Bowling Green Building, New York, for his "Electra Highest Grade Nuernberg" carbons for its entire requirements of carbons. This means that the World's Fair grounds and all the buildings, so far as the arc lighting is concerned, will be illuminated exclusively by these carbons.

REFLECTORS.—The National X-Ray Reflector Co., Chicago, manufactures a complete line of X-ray sterling silver plated glass reflectors for electric and gas lighting. In a neat catalogue just issued these goods are well illustrated, the variety of designs being the most conspicuous feature. These reflectors are corrugated spirally or radially, or both, which arrangement insures powerful reflection of the light. Mr. C. J. Purdy, 26 Cortlandt street, is the manager of the company's New York salesrooms.

THE V. R. LANSINGH COMPANY, of Chicago, is equipping the entire large booth of the Singer Manufacturing Company in the Manufacturer's Building at the St. Louis Exposition with Holophane globes. This company is also equipping the Singer Manufacturing Company's Sixth Street store in St. Louis with Holophane globes throughout. The jury room in the Electricity Building and the offices of Prof. Goldsborough, chief of the Department of Electricity, are to be equipped with Holophane globes and pagoda reflectors.

THE YALE & TOWNE MFG. CO. has made preparations to install a very extensive exhibit at the Louisiana Purchase Exposition, showing chain blocks, overhead carrier systems and labor-saving appliances in actual use, and demonstrating the vast economies represented by up-to-date hoisting and transferring methods as compared to old methods. The exhibit will contain some entirely new features in the way of improved hoisting equipment, and will be of especial benefit to engineers interested in economical handling and transferring of material.

STANLEY SYSTEM SYNOPSIS.—We have received from Mr. Ray D. Lillibridge, 170 Broadway, a copy of the "Synopsis of the S. K. C. System," which he has just issued for the Stanley Electric Manufacturing Company, of Pittsfield, Mass. This compendium, of about 48 pages, covers virtually all the products of this progressive concern, and contains the pith of a great many bulletins already issued, and gives all the facts and data in a more condensed form, but still illustrating profusely. In case the larger bulletins are desired, a numbered list of them is given.

THE INTERNATIONAL TELEPHONE MANUFACTURING COMPANY, Chicago, is receiving a large call for its new "never failing" self-restoring drop, not only for complete switchboards for new exchanges and re-equipping plants, but for extending boards of other makes. Its combination jack and self-restoring drop is arranged in strips of five and can readily be mounted on any other make of switchboard, and has the jack ferrule constructed to fit any size plug. The spring jack being designed so as not to depend on the ferrule for a connection, makes a positive and reliable plug contact at all times.

"MACHINE TOOLS" is the title of a very massive and handsome catalogue in quarto form just issued by the Niles-Bement Pond Company, of New York. It contains 713 pages, nearly every one of which is illustrated with a large well-made half-tone cut. The engravings are printed in black and the type matter is in brown ink. There are hundreds of cuts, of machine tools and parts, as well as several fine pictures of factories, medals, diplomas, etc. One section deals with electric traveling cranes which are fully illustrated and described. The cover is a brilliant red cloth and the end papers carry the repeated initials of the concern, as a device.

U. T. HUNGERFORD BRASS & COPPER CO.—The Waterbury Brass Co., No. 122 Centre Street, New York, has closed its New York store, and the entire stock has been purchased by U. T. Hungerford Brass & Copper Co., 497-505 Pearl Street, New York. This addition will, it is said, give the last-named company a larger and more varied stock (about two million pounds) of brass, copper, etc., in various forms, than was ever before under one roof. The increasing business of the Hungerford Company has rendered necessary the erection of another building adjoining its present commodious quarters, which will be ready for occupancy about April 15.

"IMPERIAL SOLDERENE" is a new and convenient preparation for soldering purposes, particularly in electrical work. It is a pure, high-grade solder, ground and mixed with special, quick-acting fluxes, and compressed into hexagonal stick form. It requires but a very low temperature in actual use, but when set a high temperature makes little or no effect. The heat applied first melts the "carrier," which requires about 180 degrees, and the carrier then becomes a conductor of heat and is volatilized as the comminuted solder fuses and adheres. Samples of work shown us are very satisfactory and complete. It is made up and put on the market at low price by W. Green & Co., Maiden Lane, New York City.

THE EUREKA ELECTRIC COMPANY, of Chicago and Genoa, Ill., is now running its factory overtime and reports a most successful spring outlook for business. Its factory has been extremely busy for the past 10 weeks, and orders are coming in very heavily on its new switchboard apparatus, which is securing a very high endorsement of all who have seen the same. The company will be pleased to send its latest 1904 bulletin and printed matter describing its well-known line of apparatus to any company desiring the same. The company has also issued a novel little folder, being a miniature facsimile of its model 99 telephone set in natural colors, showing its front appearance and the interior. It is circulating some 250,000 of these among the trade.

PLATINUM and its allied metals, which depend almost entirely upon the Ural Mountains for their crude supply, have already felt very decided results of the Russian-Japanese war, owing to heavy withdrawals of forces from this mountain district by the Russian government, the effect of which has naturally caused an advance in current rates. For some time, there has been an increasing demand for platinum and its alloys in the electrical and chemical fields, which is constantly being supplemented by the increasing use of gas engines, automobiles, and various new electrical appliances, having platinum contacts and attachments. This growing demand, with doubtless a long continuance of the present situation in Russia, would strongly point to a further advance in a very short time.

AN ECHO FROM THE BALTIMORE FIRE.—There is a boy in Baltimore who thinks that the recent fire was not such a bad thing after all. While snooping among the ruins, he came across what the fire had left of a small Crocker-Wheeler motor. He gathered up the castings and wrote to the manufacturers describing his find and closing thus: "Can I wind the armature so as to use it as a direct-current series-wound dynamo? If so, what size and how much wire must I use on the field magnet and armature? How many coils must I divide the armature into? . . . . Thanking you very much for the information you can give me," etc. Many a collector of souvenirs has carried useless things away from the scene of the fire, to be placed in curio-cabinets and on rural mantel shelves, but this young Franklin knows a trick worth two of that.

B. F. STURTEVANT Co.—Since the removal of the foundry and pattern departments from the B. F. Sturtevant Co's. plant at Jamaica Plain to its extensive new quarters at Hyde Park, Mass., the moving of the other departments has progressed in earnest. The fan, heater and electrical departments have already been moved, the engine and galvanized iron departments are in process of removal, and the erection of machines in the machine shop is well under way. These machines, as well as all the others throughout the works, will be of the most modern type and with the systems of cranes and industrial railways will enable the work to be turned out accurately, rapidly and at a minimum cost. The handsome office building is rounding into shape. The headquarters are still at Jamaica Plain, but in a few months the entire plant will be moved.

NATIONAL ELECTRIC COMPANY.—The National Electric Company, successors to the Christensen Engineering Company of Milwaukee, has recently completed and is now occupying a handsome new office building adjoining its shops. The company is about to adopt a plan of providing free dinner for its officers, employees in the executive and the engineering departments, and the heads of the various other departments. Two pleasant dining rooms, a butler's pantry and a kitchen have been fitted up in the new office building. One dining room will be for the officers of the company and its guests. The second will be for the employees of the offices and the engineering department. The new office building is 200 by 66½ feet, three stories in height, the outer walls being of large cement blocks which were manufactured at the plant. The building is absolutely fire proof. Six hundred men are now employed at the works.

BEEBE & BENNETT.—Messrs. Murray C. Beebe and Edward Bennett have, under the above firm name, established general engineering and contracting offices in the Farmers' Bank Building, Pittsburg, Pa. Mr. Beebe was until recently with the Nernst Lamp Company as chemist and technical superintendent, from which company Mr. Bennett has recently severed his connection as chief electrician. Associated with the firm are engineers having a wide experience in the design and construction of railway, light and power plants. The firm is prepared to act as consulting and supervising engineers for the construction of railway, light and power plants, or to contract for the complete erection of such installations. It will examine and report on the mechanical equipment and the methods and systems in use in factories, and submit complete lighting plans for large installations. Examinations and reports will be made of the value of apparatus, properties, or systems.

THE STANDARD UNDERGROUND CABLE COMPANY announces the recent opening of a branch office or headquarters in the Security Building, St. Louis, Mo., in charge of Mr. W. A. Caldwell, who was formerly connected with the Chicago office of the company, but more recently with the home office at Pittsburg. Mr. Caldwell had a number of years' experience with the company in both the construction and sales departments. This company has now seven district or branch offices throughout the country, covering it from Maine to California, namely: The northeastern sales department, Delta Building, Boston, Mass.; the eastern sales department, 56 Liberty Street, New York City, N. Y.; the southeastern sales department, Betz Building, Philadelphia, Pa.; the central sales department, Westinghouse Building, Pittsburg, Pa.; the western sales department, the Rookery Building, Chicago, Ill.; the southwestern sales department, Security Building, St. Louis, Mo.,

WESTINGHOUSE MOTORS.—The Westinghouse Electric & Manufacturing Company has just issued two circulars, Nos. 1077 and 1078, the former relating to type L motors, direct current series wound, and the latter to No. 91 single-phase railway motor and car equipment. The type L motor is widely used for hoisting and other intermittent service requiring large torque. It is well suited for work in mills, foundries and other manufacturing plants. Different applications of this motor are well illustrated, and the principal features of design and construction described. Various curves show the efficiencies, torque, speeds, etc., of different sizes of this type of motor. At the back is a list of the company's circulars in force March 1. The No. 97 single-phase railway motor is described and illustrated in a similar manner in circular 1078, and diagrams show the connections of the apparatus. This motor was described and illustrated in our issue of February 20, last. The advantages of this single-phase railway system are briefly pointed out. Copies of these circulars can be had on application.

THE ELECTRIC STORAGE BATTERY CO., of Philadelphia, is continually adding to its list of Exide battery depots, the list now including twelve cities. These Exide stations instituted for the purpose of the prompt delivery and care of batteries have proven to be of great convenience to the public, and the rapidly increasing demand for batteries has necessitated the opening of new depots at central points. Each of these depots is under the care of an experienced storage battery man, and being stocked with a full line of battery material, users of electric vehicles, equipped with the Exide battery, have at convenient points the same facilities for attention, and procuring supply parts, as they would have if they were at the factory of the company. These stations are located in New York City, 8th Ave. & 49th St.; Philadelphia, 250 North Broad St.; Pittsburg, 5905 Centre Ave.; Buffalo, 200 Pearl St.; Chicago, 204 East Lake St.; Denver, 1510 Court Place; Boston, 39 Stanhope St.; St. Louis, 809 Walnut St.; Rochester, 150 South Ave.; Toledo, 715 Jefferson Ave; Detroit, 265 Jefferson Ave; Columbus, 4th & Gay Sts.

HAULING-IN CABLES.—The Knickerbocker Construction Company, 15 Cortlandt Street, New York, which makes a business primarily of the hauling of heavy electric cables into underground conduits, has acquired the right to use the Grinnell hauling machine, which is a marked improvement on previous devices for this purpose. The apparatus is such that it is easily loaded on cars, and the company is prepared to go anywhere in the United States where the work warrants. It has in its organization competent skilled men in all its branches capable of doing the particular kind of work they will be called upon to do. In addition to the hauling-in of a cable the company makes where necessary the splices in accordance with any specification. It also will lay the conduits, build the manholes, and in short, do the work of complete construction from the excavation and laying of the ducts including manholes and carrying out all details, including drainage to the sewers, gas proofing, etc. Mr. J. W. Cushing, secretary and treasurer of the company, is a Massachusetts Institute of Technology man, and Mr. Whieldon, vice-president and general manager, is a member of the American Institute of Electrical Engineers.

THE BRILLIANT ELECTRIC CO., Cleveland, Ohio, manufacturer of incandescent lamps, has started a novel idea by founding a correspondence course such as would enable anyone taking it thoroughly to operate with efficiency an electric light plant. The company does not propose to issue any text books, but the student is at liberty to buy anywhere for himself such as are recommended. The instruction will consist of reference to standard text books, and answers to personal difficulties as they arise with the individual student. The company says: "The student who obtains valuable information free can certainly not object to our using the backs of letters, etc., for advertising purposes; and it is our intention to give such information in our letters that they will be permanently kept for reference, thus preserving our advertising and bringing it continually to the notice of the engineer." As to the relation of this ingenious plan to its business, the company says: "Incandescent lamps are something that are unfortunately very easily juggled with, but as the buyers or users become more familiar with them, the less opportunity there is for misrepresentation. We base our claims for patronage wholly on the quality of our product; hence our desire to educate the buyer so that he can intelligently discriminate between the good and the poor." The course will be given, however, whether the student purchases Brilliant lamps or not.

THE STANDARD VITRIFIED CONDUIT COMPANY, of 39-41 Cortland Street, New York, completed recently its plant at South River, N. J. Owing to the great demand for conduit manufactured by this company, its plant has run continuously since beginning operations in 1902. In this time an enviable reputation has been gained by its promptness in delivery of a strictly high-grade material. Under patents of Mr. R. W. Lyle, this company is manufacturing multiple duct conduit. It also furnishes free to its customers, with the single duct, its own patented mandrel for laying single duct, which yields great economy in construction. Ample stock of both standard and special sizes together with fittings, kept on hand for delivery on short notice, enables this company to hold its independence in the trade. Forty million feet of conduit annually can be produced by its factories. Among the largest buyers of the Standard vitrified conduit are: The Bell Telephone Co., New York, Boston and Southern States; Rapid Transit Subway Const. Co., (New York tunnel); Manhattan Elevated, Met. St. Ry. Co., Consolidated Tel. & Elec. Subway Co., New York Edison Co., Brooklyn Edison Co., Brooklyn Rapid Transit Co., Boston Elevated Railway Co., The Philadelphia Edison Co., The Philadelphia Rapid Transit Co., New York Tunnel Co., Westinghouse, Church, Kerr & Co., United Engineering & Const. Co., Western Electric Co., Standard Underground Cable Co., Safety Insulated Wire & Cable Co., Pennsylvania Railroad Co., Baltimore & Ohio R. R. Co., New York Continental Jewell Filtration Co., Hudson River Water Power Co., Glens Falls, N. Y.; Niagara Falls Power Co. The Company's illustrated catalogue, which is a work of art, can be had on application.

CABLE PROTECTION WITH "NIAGRITE."—Electrical power houses carry their currents away from the buildings through conduits or tunnels, and rest the cables on arms or branches usually one branch or arm above another. The over-heating of the wire in the cable sometimes melts the insulating compound and brings two uncoated wires together. This creates a short circuit with the consequent burning and fusing of the wires. This sets fire to the insulation as well as to the outer coating or wrapping, which is usually of cotton braid. The fire is thus communicated to the next cable, which may have been intact, until this trouble set in. This cable is burned from the outside inward again releasing more energy and setting fire to innumerable cables. To prevent this condition, the H. W. Johns-Manville Co., New York, has devised an insulating covering for the cables, which fire-proof these cables so as to prevent, in case of short circuiting of one, the ignition of the others. It was first used by the Niagara Falls Power Co., hence its name "Niagrite." It is made in the following thicknesses-3-32", 1/8", 1/4", 3/8". It is supplied in strips 36" long and 3" wide, and with them is sent sufficient fire-proof glue in which to immerse and coat the strips ready for application. "Niagrite" is absolutely fire proof. The application is easy, and the expense very nominal compared with the amount of protection afforded. Mr. H. W. Buck, electrical engineer of the Niagara Falls Power Co., was the first man to use "Niagrite." He has given orders for about 50,000 lineal feet, and proposes to finish up the remainder of his plant, which will require about 450,000 feet more. The Falls Power Co., of Buffalo, N. Y., also uses it.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED APRIL 5, 1904.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., New York.]

756,219. WIRELESS TELEGRAPH RECEIVING SYSTEM; Eugune Ducretet, Paris, France. App. filed Aug. 14, 1903. An oscillation transformer whose primary and secondary windings consists of flat spirals superposed one on the other and means for making electrical connection with various parts of each spiral, whereby the number of effective turns is varied.

756,242. ELECTRIC HEATER; Robert Kuhn, Detroit, Mich. App. filed Oct. 7, 1902. A cooling utensil in the form of a double boiler with the heating resistance wound in the intervening space between the two vessels.

756,275. ELECTRIC SIGNALING DEVICE FOR ELEVATORS; Fred S. Payne, Boston, Mass. App. filed Aug. 11, 1903. Details.

756,316. ELECTROMAGNETIC RAILWAY SWITCH; Rollin A. Baldwin, South Norwalk, Conn. App. filed Dec. 18, 1902. Two solenoids acting upon a single armature to move the switch in opposite directions and cut-outs for automatically throwing the current into the proper solenoid and holding it there until the solenoid has done its work.

756,344. CIRCUIT BREAKER; Leonard L. Elden, Boston, Mass. App. filed June 20, 1901. A plurality of actuating coils and their armatures, one in each circuit liable to be affected by an abnormal current, and tripping mechanism automatically operated thereby for opening the circuit breaker.

756,408. CALL OR ALARM DEVICE FOR HOTELS OR OTHER BUILDINGS; Harvey Reed, Minneapolis, Minn. App. filed Sept. 4, 1902. Details.

756,412. SUPPORT FOR INCANDESCENT ELECTRIC LAMPS; Adolphe Romain and Jean D'Ayguesvives, Paris, France. App. filed Oct. 10, 1902. One or more sockets are attached to a central fixture in which the fuses are located.

756,445. RHEOSTAT; Henry J. Wiegand, Milwaukee, Wis. App. filed June 1, 1903. A base provided with a central projection and a rim, and having an annular recess in which the contact plates and resistance coils are located and covered by a suitable insulating material.

756,541. ELECTRIC SWITCH; Peter Sorensen, Brooklyn, N. Y. App. filed Nov. 23, 1900. A clock-actuated switch capable of a quick break and a quick make of the circuit.

756,547. TROLLEY POLE; Edwin A. Wakefield and George W. Morse, Mechanic Falls, Me. App. filed Dec. 18, 1903. Mechanism for lowering the pole in case it rises above the wire.

756,550. TROLLEY; Charles M. Wilson, St. Louis, Mo. App. filed Feb. 18, 1904. A spiral groove formed at each side of the contact groove of the trolley roller to conduct the wire when displaced back to the center.

756,605. CURRENT REGULATORS; Emil Dysterud, Monterey, Mex. App. filed June 9, 1903. A liquid tank having two compartments and a valve in the separating partition which is moved automatically to vary the body of liquid standing in the opening to vary the current which may travel through the liquid between two electrodes located in the respective compartments.

756,608. ANNUNCIATOR; Franklin H. Elwell, Chicago, Ill. App. filed July 9, 1902. Details.

756,627. INSULATOR; John A. Hanson and Albert F. Lambert, Davenport, Wash. App. filed June 14, 1902. A two-part insulator block between the parts of which the conductor is confined and which are held in position by a straddling staple driven into the supporting wall.

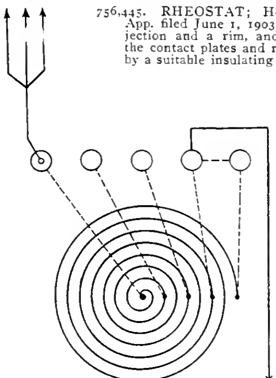
756,665. APPARATUS FOR TESTING THE INSULATION OF THE COILS OF ELECTROMAGNETS; James Lindsey, Fall River, Mass. App. filed Feb. 1, 1904. An electric buzzer for determining by means of the resulting difference in sound, the comparative quality of the insulation of a coil with that of a standard sounding coil.

756,676. WAVE RESPONSIVE DEVICE; Frederick W. Midgley, Philadelphia, Pa. App. filed Nov. 10, 1902. The device comprises two masses of similar or dissimilar composition, one of them having a coating of oxide, while the other is burnished.

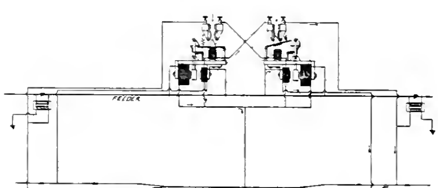
756,711. ELECTRIC CONTROLLER FOR ALTERNATING CURRENTS; Robert P. Rukenbrod, Turtlecreek, Pa. App. filed Jan. 26, 1903. Details.

756,718. WIRELESS SIGNALING SYSTEM; Harry Shoemaker, Philadelphia, Pa. App. filed Aug. 9, 1902. A system for receiving wireless signals which depends upon the change of resistance of a conductor due to the heat produced in it by the arriving energy.

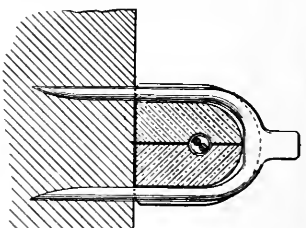
756,719. SIGNALING SYSTEM; Harry Shoemaker, Philadelphia, Pa. App. filed Aug. 19, 1902. A method patent relating to the subject of the preceding patent.



756,219.—Wireless Telegraph Receiving System.



756,511.—Electric Railway.



756,627.—Insulator.

756,460. ELECTRIC ARC LAMP; Andre Blondel, Paris, France. App. filed Nov. 10, 1902. The fumes produced by mineral electrodes are carried away by suitable ventilating passages to prevent their access to the lamp mechanism.

756,511. ELECTRIC RAILWAY; Thomas D. Lovell, Beverly, Mass. App. filed Nov. 3, 1903. A safety system for single track roads in which the entrance of a car to a block automatically cuts off current from a section of the trolley wire at the opposite end of the block to prevent a car entering from the opposite direction.

756,516. AUTOMATIC ELECTRIC CUT-OUT; Guy Milburn, Baltimore, Md. App. filed March 31, 1903. Details.

756,523. AUTOMATIC POWER CUT-OUT FOR ELECTRIC RAILWAYS; Harry F. Pieper, New York, N. Y. App. filed Jan. 5, 1904. An arrangement of circuits and apparatus by which a car on a block using either power current or lamp current will prevent the entrance of another car to the same block from behind, by taking current therefrom.

756,534. CIRCUIT CONTROLLER; Jacob L. Schureman, Jr., Chicago, Ill. App. filed Jan. 11, 1904. The arm of a rheostat has a lost-motion connection with a dash-pot, permitting it to quickly close the circuit on the first point and thereafter move slowly over the succeeding points to cut out the resistance.

756,720. WIRELESS SIGNALING SYSTEM; Harry Shoemaker, Philadelphia, Pa. App. filed June 25, 1903. The invention consists in supplying to a freely oscillating circuit, direct current energy and employing the energy of the high frequency oscillations resulting in the oscillating circuit for any purpose whatsoever.

756,724. INSULATORS; John C. Snodgrass, Steubenville, Ohio. App. filed Aug. 26, 1903. An insulating block having a V-shaped projection partially entering a similarly shaped orifice to hold a stretched conductor in a deflected condition within the insulator.

756,757. THIRD RAIL ELECTRIC RAILWAY SYSTEM; John D. Wilkins, Chicago, Ill. App. filed July 24, 1903. A covering for a third rail consisting of a string piece made in two longitudinal sections bolted together.

756,777. ELECTRICAL ANNUNCIATOR; Albert Carliss, Chicago, Ill. App. filed Oct. 5, 1901. Details of construction.

756,782. CIRCUIT BREAKER; Leonard L. Elden, Dorchester, Mass. App. filed Dec. 10, 1903. Details of construction of the tripping mechanism.

756,793. ELECTRICAL INDUCTION MACHINE; Hans Lippelt, New York, N. Y. App. filed Jan. 13, 1903. A construction of machine intended to avoid sparking at the collectors.

Electrical World and Engineer

THE CONSOLIDATION OF "THE ELECTRICAL WORLD" AND "ELECTRICAL ENGINEER."

VOL. XLIII. NEW YORK, SATURDAY, APRIL 23, 1904. No. 17

ELECTRICAL WORLD AND ENGINEER

Published weekly by the

McGRAW PUBLISHING CO.

114 LIBERTY STREET, NEW YORK.

TELEPHONE CALL: 7605 CORTLANDT. CABLE ADDRESS: ELECTRICAL, NEW YORK.

EDITED BY T. C. MARTIN AND W. D. WEAVER.

CHICAGO OFFICE - - - - - - 1139 Monadnock Block.
PHILADELPHIA OFFICE - - - - - - 929 Chestnut Street.
EUROPEAN OFFICE, Hastings House, Norfolk St., Strand, London, Eng.

TERMS OF SUBSCRIPTION.

United States, Canada or Mexico	Per year, $3.00
Foreign Countries, within the Postal Union	6.00
Great Britain and Ireland	25 shillings
Germany	25 marks
France	31 francs
Single copies	.10

Remittances for foreign subscriptions may be made through our European office.

In requesting your address changed give OLD as well as new address.

CONTENTS.

THIRD RAIL IN WINTER.

Although snow is hurtling past the windows while we write this little item, it is fair to assume that the winter approaches its end, and that although the snowdrifts are still quite heavy up the State and the tinkle of the sleighbell is still heard in the land, New Yorkers at least are likely now to enjoy several months respite from the severe discomforts of the Arctic regions such as they have been enduring lately. It is certainly a matter for congratulation that during the strenuous period from last October down to the present moment, the Manhattan Elevated system has, on the whole, proved itself so thoroughly adequate, technically considered, to the great burden of travel thrown upon it. Time and again during the winter street car travel has been seriously impeded and delayed, not because the cars were unable to run, but because, owing to the amount of snow and ice on the ground, all other vehicles and traffic stuck closely to the car tracks. Hence, people in street cars have frequently abandoned them in order to take to the elevated road, and whenever this has been done they found the cars there in full operation making usual headway with commendable speed and regularity. In one day last January the road carried without any kind of trouble 1,046,000 passengers. Three times this month the number has exceeded 1,000,000, and on the first Monday of this month 1,063,000 fares were paid. It is possible that even since we noted these facts the record of April 4 has been eclipsed.

Be that as it may, it would certainly appear that the third-rail system, in spite of all its drawbacks, has been made a remarkable success. The Manhattan Elevated management is transporting the population of this city more swiftly and more comfortably than ever before, and it is only fair that words of praise should be expressed. We are the more ready to extend our congratulations to the officials in view of the reasonable dissatisfaction which we uttered a year ago and in view also of the tremendously severe winter, during which the company has now made this wonderful record. It seems to us that the third-rail system has inherent defects and difficulties of its own, but these the company is not responsible for, and it would doubtlessly welcome improvements more promptly than anybody else. Nor is it fair to hold the company responsible for the crowding which is still a concomitant of the situation. The road has more cars in operation than ever before, and, in fact, the trains are so thick in the rush hours they are beginning to cut down the headway again, and thus offset some of the advantages of rapid acceleration. Mr. W. B. Parsons, chief engineer of the Subway Road, has said that the growth of traffic in New York City is so great that virtually a new subway system is needed every four years to keep the transportation facilities abreast of the demand on them. This being broadly true, we think it must be conceded that the Manhattan Road, under the régime of electricity, is doing remarkably well, and that there is ample encouragement for the further extension of transportation lines on this island.

WORLD'S FAIR ELECTRIC RAILWAY TESTS.

Elsewhere we print the reports of two of the four advisory engineering committees appointed by the Electric Railway Commission, under whose authority comprehensive tests of electric railway apparatus and systems will be conducted at the St. Louis Fair. The result of the programme adopted by the committee should be of unique value, and no small part of the success which may be confidently anticipated will be due to the admirable organization of the work and the excellent judgment displayed in the selection of the personnel. As previously outlined in these columns, the commission is composed of five members who were selected for their prominence in various departments of the electric railway industry. Four committees were named by the commission to draw up programmes of tests to cover, respectively, city and suburban, interurban, heavy traction equipments and new electric railway systems. For carrying on the actual work of test another committee has been appointed which will be assisted by a staff of electrical engineering students graduating the present year. These young gentlemen during the remaining part of their college technical course will be specially instructed in the details of the testing work with which they are to deal. Finally, an advisory committee representing the manufacturers whose apparatus is to be tested, has been appointed. We repeat the above details of the organization for the reason that we desire to give prominence to what appears an ideal solution to what in the past has been found a difficult problem in connection with world's fair tests. The exceptional opportunities for this class of work at international expositions have heretofore yielded but meagre results and largely, we believe, on account of lack of proper organization of programme and of insufficient thought being given to the important matter of selection of personnel. The plan worked out in the present instance might well be adopted as a model for other tests that may be undertaken at the St. Louis Fair, and its success will undoubtedly have an important effect in directing more active attention than has in the past been given to the great desirability of taking full advantage of the opportunities offered by international expositions for the collection of engineering data.

Telegraph and Telephone.

There have been one or two curious and interesting symptoms and indications of late, of a closer drawing together of telegraph and telephone men. Some of our readers have been quite surprised at the revelations in Mr. Stanton's recent article in our pages, detailing the extent to which telegraphy is now done over the independent telephone circuits of the Middle States, and intimating that such work is likely to go a good deal further. That, however, is but one chapter in the development at the present time. Some of the financial journals do not hesitate to suggest an impending merger of telegraphic and telephonic interests on a large scale, and even foreshadow an approaching consolidation of Postal and Bell Telephone systems. As a guess this may not be far out of the way, and does but repeat gossip noted by us quite frequently during the past year or two. Now we are informed that a "deal" of this kind would save the telephone company alone not less than $2,000,000 in operation and $20,000,000 a year in construction. It is just as well to make the figures large while you are about it.

Incidentally, there are suggestive side lights on the situation, as, for example, the fact of Messrs. Mackay and Murray Crane becoming fellow directors in a big New York trust company, which might help in the financial negotiations. Another incident is the dinner this week given by the Magnetic Club of telegraphers to the telephonic leaders around New York, and probably including Prof. Bell. We can but admire such a rapprochement, and if it helps the cause along well and good. In past days telegraphers have let the telephonists drift a long way from them, and a little hearty hospitality is certainly timely by way of indicating, in any respect, the reunion and harmony of the two branches of the family. We are glad to note the dinner and shall await with interest the other developments, if there be any beyond the simple exchange of sentiments of mutual esteem and good will.

The Elementary Principles of Transformer Design.

Transformers have now been in commercial use for over twenty years, and a great variety of structures and arrangements have been tried in their development. There is but little chance left for their improvement in efficiency, since in very large sizes the full-load efficiency is known to be about 98 per cent. Consequently, only a margin of loss amounting to 1.3 per cent. at full load remains for future discoveries to save. Nevertheless, there is always a wide field open for cheapening the construction, improving the pressure regulation, compacting the apparatus, increasing the dielectric strength, etc. The design of a transformer, like that of any other electromagnetic apparatus, is a struggle for ascendancy among a number of desiderata, effecting a final compromise. A designer aims for low cost of construction, low weight, high efficiency at the mean load, small excitation current, small temperature elevation, compactness, good pressure regulation, high dielectric strength and convenient shape. Many of these desiderata are in mutual opposition. If the designer is directed to lay particular stress upon one particular requirement, the design will be changed to suit the favored protégé. In general, a compromise between all the requirements, in some relation to their mutual relative importance is aimed at.

It is probably impossible to obtain a general equation in which all these different factors enter, and from which a solution, for any assigned values of all the factors, may be evaluated. If this were a physical possibility, it would probably be a mathematical prodigy, and the labor involved in solving the equation would, perhaps, exceed that necessary for computing the elements of a solar eclipse. Nevertheless, the behavior of a transformer is subject to rigid physical laws, and the design of a transformer should be shorn of empiricism, if progress in the art is to continue. It is important that the theory should be so far developed that for each and every design that may be suggested, the corresponding practical results in each direction may be capable of computation. Moreover, the relatively much simpler processes of computing the dimensions of a transformer for maximum efficiency alone, or for minimum weight alone, or for minimum cost alone, may profitably be studied by electrical engineers. The article by Prof. Thomas Gray, the first part of which appears on page 765, deals mainly with the problem of maximum efficiency.

Electricity and the Weather.

Whenever a fire occurs in a building that has once been wired for electric lighting, it is very convenient, in cases where the origin of the fire is not immediately apparent, to attribute the outbreak to a cross between the electric wires. This satisfies the imagination, calls for no defense on the part of the householder, and covers a multitude of sins. If the electric light company dares to protest against the indictment, it should not be credited, because it is a wicked corporation operated for selfish greed. Something of like looseness of thought and expression is suggested by a paragraph recently appearing in a prominent daily newspaper giving a telegraphic account of the foundering of the late Russian battleship *Petropavlovsk*. After describing the terrible explosion, the account went on to say that the vessel foundered owing to having "lost her center of gravity." Whether the missing center of gravity was blown out of the ship by the explosion, or was accidentally dropped overboard by one of the sailors during the immediately subsequent excitement, is, unfortunately, not stated in the telegram. Curiously enough, the vagaries of the weather are not usually attributed to electricity. In the popular mind it is usually the other way, and manifestations of electricity are commonly attributed to the weather. It is a grateful and comforting reflection that the weather is one of the few things for which crosses between wires are not made responsible.

In the annual summary, however, of the Monthly Weather Review for 1903, recently issued by the United States Weather Bureau, there is an interesting section devoted to the subject of seasonal or annual forecasts. Not only are weather men becoming expert at foretelling the weather a day ahead, but they are evincing ambitions to let us know our troubles a year ahead. Some day who knows but that the Nautical Almanac, which is computed four years ahead, and printed three years ahead, eclipses and all, will have an extra weather column, giving the weather at all parts of the globe for each date. At all events, the section above referred to very clearly and logically points out that changes in the weather of the sun precede long changes in the weather, or seasonal changes on the earth. The desirability of more closely studying the electromagnetic action of the sun upon the earth, as one of the factors in the maintenance of solar influence, is pointed out. In reality, the variations in the electric and magnetic influences of the sun are at the present time more clearly capable of being detected and measured than variations in its radiated heat, or in the solar climatology.

WIRELESS IN WAR.

The strenuous manifesto of the Russians against the use of wireless telegraphy by neutrals within the zone of hostilities is timely and to the point. It has, to be sure, a pungent flavor that will hardly commend it to the representatives of the daily press, but it is well that we should understand that modern war is neither a golf match nor a yacht race, and that whosoever intrudes upon it does so at his peril. We presume that there will be protests about the liberty of the press, the rights of neutrals, and Muscovite barbarism; but the fact remains that although the introduction of wireless telegraphy has introduced a new and important feature into war correspondence, Russia is apparently well within the rights insured to belligerents by the ordinary precedents, or absence of them, which make up the body of international law. That the protest has come from Russia rather than Japan is simply an indication that the former, under the sting of defeat and disaster, feels more acutely the necessity for it. We should much dislike to be on board a press boat which had been warned off from dogging the fidgety fleet of the genial and versatile Admiral Togo. There has been no proclamation, but a twelve-inch projectile is quite sufficiently exterminatory, and it is not always easy to distinguish signals in a bad light. In point of fact, the Japanese regulations for war correspondents are quite as drastic as the Russian, and neither are unusually or objectionably severe from the standpoint of international law. They are stricter than those in vogue here during the Spanish fracas, but one of the weakest points in our military and naval system is the undue weight given to impertinent and incompetent "public" opinion.

Let us look a little into the status of wireless telegraphy, and see what are the precedents by which it must be determined. It is, of course, a new method of transmitting intelligence, but in its results it is the same so far as the interests of the belligerents are concerned. Its long range gives it unusual powers, good or ill, which must be taken into consideration. Now to begin with, a wireless telegraph outfit on its merits as merchandise, would unquestionably be held to be contraband of war if consigned to a belligerent and would be subject to seizure like any other contraband article even upon the high seas. It is no less contraband if found actually in use to the advantage of a belligerent, even if in the possession of a neutral and upon the high seas. As to the full personal responsibility of the users, no question can properly be raised under the rules and usages of war. To quote from our own Articles of War: "Whosoever shall be convicted of holding correspondence with, or giving intelligence to, the enemy, either directly or indirectly, shall suffer death, or such other punishment as shall be ordered by the sentence of a court-martial." And in time of war a court-martial is fully recognized as having complete jurisdiction over violaters of this article whether they owe allegiance to the United States or not. No man who circulates about in the zone of hostilities collecting and disseminating information with a hand ever so impartial, can be excused on the ground that he is a neutral, or that he is gathering news for the general benefit. If his acts are such as are in themselves calculated to convey even indirectly, information concerning one belligerent to the other, he must, if caught, take his chances of noose or bullet, for he is trespassing on the playgrounds of Death, and doing it knowingly. Nor can he escape because his operations within the zone of hostilities chance to be upon the high seas, which are not neutral territory, but merely the common highway of nations on which belligerents are accorded paramount rights. It will be interesting to watch the action of the American Government in the premises.

A wireless press message sent from the seat of war to neutral territory endangers the rights of belligerents peculiarly for two reasons. First, it is at best intended for general publication, which implies conveying news of the acts or intentions of one belligerent to the other. Second, it may by accident or pre-arrangement be directly intercepted. In either case the sender is clearly in the position of giving information forbidden by the usages of war. Even when the zone of hostilities is upon the high seas, neutral vessels enter it, unbidden, at their peril, and cannot act as spies or conveyers of information except at their own risk. Even war vessels of neutral nations upon the scene for purposes of private observation with the acquiescence of the belligerents, must be extremely circumspect in their acts. We do not think we overstate the case in saying that for a war vessel of a neutral power to send wireless dispatches for publication to a neutral port giving information to all the world of the movements of belligerents, would properly be considered an unfriendly act by the injured belligerent and would constitute a justifiable *casus belli* if repeated. We have all sympathy with the hard and dangerous task of a war correspondent; it is in every way desirable that neutral powers should learn of the progress of hostilities, but it is well within the rights of belligerents to determine in how far it is safe to allow their movements in the zone of hostilities to be made public, to regulate the transmission of news from within their own lines and throughout the region in which they are operating, and to suppress, if need be by extermination, the injurious acts of spies, eavesdroppers and busybodies, within the entire zone of hostilities. Trespassers in that zone must remember that their rights there are secondary to those of the belligerents, and that no professions of neutrality will excuse them in hostile acts, in which category the unauthorized sending of wireless messages must certainly be placed. There is no international law forbidding it, but it is done at the sender's imminent peril. And even if some dictum or precedent in international law could be adduced apparently favorable to the opposite view, it would not avail against the principle of self-preservation, which in affairs of nations can always be appealed to as paramount. In fact, lacking a tribunal for its interpretation with command of bodily means for its enforcement, the so-called law of nations may be likened to the "gentlemen's agreement," of which the keeping depends on self-interest—especially the self-interest of the stronger party. Meantime, Russia will go slow and as a matter of electrical technique we are heartily glad to see such splendid work done with wireless telegraphy, in messages hundreds of words long—and with American apparatus at that, in American hands.

International Electrical Congress.

We are informed that the following papers are promised for Section A—the section on "Theory"—of the Congress, of which Prof. E. L. Nichols is chairman and Prof. H. T. Barnes secretary:

FOREIGN.

Prof. Dr. Paul Drude, "Metallic Conduction"; Prof. Dr. W. Jaeger, "Electrical Standards"; Sir Oliver Lodge, F.R.S., "Ions"; Prof. H. Nagaoka, "Magneto-Striction"; Prof. Dr. J. J. Thomson, F.R.S., subject to be announced; Prof. J. S. Townsend, F.R.S., "The Theory of Ionization by Collision"; Mons. J. Violle, "Secondary Standards of Light"; Mr. C. T. R. Wilson, F.R.S., "Condensation Neuclei"; Prof. P. Zeemann, "Magneto-Optics."

AMERICAN.

Prof. H. T. Barnes, "The Mechanical Equivalent of Heat as Measured by Electrical Means"; Dr. Carl Barus, "Atmospheric Neuclei"; Dr. Louis A. Bauer, "The State of Our Knowledge Regarding the Earth's Magnetism"; Prof. D. B. Brace, "Magneto-Optics"; Prof. H. S. Carhart and G. W. Patterson, Jr., Ph.D., "The Absolute Value of the Electromotive Force of the Clark and Weston Cells"; Prof. C. D. Child, "The Electric Arc"; Dr. K. E. Guthe, "Coherer Action"; Prof. E. P. Lewis, "Electrical Discharges in Gases"; Prof. L. T. More, "Electro-Striction"; Prof. E. Fox Nichols, "The Unobtained Wave Lengths Between the Longest Thermal and the Shortest Electric Waves yet Measured"; Prof. E. L. Nichols, "Standards of Light"; Harold Pender, Ph.D., "Magnetic Effect of Moving Charges"; Dr. M. I. Pupin, "Electrical Theory"; Dr. Edward B. Rosa, "Alternating-Current Measurements"; Prof. E. Rutherford, "Radioactive Change"; Prof. J. C. McLellan, "Radioactivity of the Atmosphere"; Prof. J. Trowbridge, "Electrical Discharge in Gases"; Prof. A. G. Webster, "Electrical Theory."

A meeting of the Congress Committee on Organization is scheduled for April 23 at 1.30 P.M., in New York. All Congress officers have been invited to attend. The meeting will be at 95 Liberty Street, New York, at the offices of the American Institute of Electrical Engineers.

Acceptances of membership in the Congress number over 1,300, up to the present time, and 150 papers have been promised in all. The following societies have all promised to hold conventions at St. Louis during the Congress week, and to hold conventions with one or more sections of the Congress:

The American Institute of Electrical Engineers, American Physical Society, American Electro-Chemical Society, American Electro-Therapeutic Association, International Association of Municipal Electricians. The British Institution of Electrical Engineers has also arranged to co-operate under some plan, the details of which have not yet been determined.

The following bodies have promised to co-operate by sending delegates. The Société Internationale des Électriciens, National Electric Light Association, Association of Edison Illuminating Companies. Co-operation is expected from various other societies.

United Engineering Building.

The Conference Committee on the United Engineering Building having selected its six architects as already announced, has now completed arrangements with Prof. W. R. Ware to act as its professional adviser in the matter of the architectural competition. His preliminary report on the subject is to be made to the committee during the present week, when a programme of competition will be agreed upon and put in final form for distribution. In addition to the selected firms, other architects will be invited to enter a free competition open to all in good standing and four equal prizes will be awarded for the four best designs. Prof. Ware has had a wide experience as a professional adviser in large competitions of this character, and is most highly regarded throughout the country for his educational and architectural record. He was for several years professor of architecture at the Massachusetts Institute of Technology, and from 1881 until quite recently was professor of architecture at Columbia University in New York City. The committee considers itself happy in having the benefit of his advice and experience.

A Gas Episode at Mt. Vernon, N. Y.

What might have been a frightful disaster, in the attendant loss of life, was narrowly averted at Mount Vernon, a suburb of New York City, on Sunday night, April 17. Had the incident occurred later in the evening the many narrow escapes reported would have been fatalities. To the quick action of Police Sergeant Walter Grant in sending in an alarm of fire, the commendable efforts of the telephone girls in arousing two thousand subscribers by violently ringing their telephones, and the inspection of every house by firemen and police, the 25,000 people of Mount Vernon and the 5,000 residents of Pelham and North Pelham and Pelham Manor owed their escape from asphyxiation by gas fumes. A valve cock on one of the big mains, it is alleged, which supplies Mount Vernon with gas broke and the gas went out for a few moments. Then the Westchester Lighting Company apparently turned the gas on again through the open jets. Many families had retired, leaving their gas burning in the sleeping rooms or else had gas logs and radiators burning to keep warm in lieu of furnaces, and the gas, it is said, made more than 100 persons ill. The arc lights on the streets saved the town from utter darkness. It is said that pandemonium was let loose in the efforts to wake people up in the 5,000 houses that constitute the suburb. The noise was kept up till 2 A.M. with a siren steam whistle and all the fire engine gongs.

A Ukase Against the Wireless.

Last week we gave some very interesting details about the enterprise of the London *Times* in equipping a small steamship and land station at Wei-Hai-Wei with the De Forest wireless telegraph system, by means of which that dashing correspondent, Col. James, has been sending brilliant and unique dispatches from around Port Arthur to that journal and the New York *Times*. Immediately following upon that article came the news that at Washington, on April 15, the Cabinet discussed a communication received by the State Department from Count Cassini, the Russian Ambassador, which apparently means that the Russians intend, if they capture any press correspondent using wireless telegraphy either near land or on the high sea, to treat him as a spy and hang him. It is understood that similar communications were made to the Foreign Office of other nations. The note received by Secretary Hay is as follows:

"I am charged by my government, in order to avoid all possible misunderstanding, to communicate to your Excellency that the lieutenant of his Imperial Majesty in the Far East has just made the following declaration:

"'In a case in which neutral steamers having on board correspondents who might communicate war news to the enemy by means of perfected apparatus not being yet foreseen by existing conventions would be arrested near the coast of Kwan-Tung or in the zone of operations of the Russian fleet the correspondents will be looked upon as spies and the steamers furnished with wireless telegraphy seized as prizes of war.'"

This action has created a sensation and is now under vigorous discussion on both sides of the Atlantic. It is referred to editorially by ourselves in this issue. According to advices from London, the communication from the Russian Government to the British Foreign Office intimates that Russia does not contemplate any immediate action in the matter.

N. E. L. A. Preparations.

The programme for the 27th convention of the National Electric Light Association is taking definite shape. Papers and reports ready are as follows: "Wrinkles," edited by Chas. H. Williams, of Madison, Wis.; "Report on District Heating," E. F. McCable, chairman; "Report on Purchased Electric Power in Factories," W. H. Atkins, chairman; "Report on Advertising," Le Rue Vredenburgh, reporter; "Report on Decorative and Sign Lighting," Arthur Williams, reporter; paper entitled "The Sale of Electrical Energy," by W. F. White; "Practical Notes on Steam Turbines," by Francis Hodgkinson; "A One-Hundred-Mile Transmission Line," by Robert Howes; "Economy Test of 5,500-hp Engine and Generator," by Messrs. J. D. Andrews and W. F. Wells; "The Remote Control of Electrical Apparatus," by W. H. Cole. It has been decided to hold the meeting for four days, the last day to be reserved largely for entertaining, etc.

Electric Distribution to Small Manufactories at Sant Mortier, France.

By Franz Koster.

The French Jura, adjoining Switzerland, near Lake Geneva, is one of the richest departments in France in manufacturing industries, being replete with factories and workshops of many descriptions. The principal industries are watchmaking, the manufacture of tobacco pipes, especially at St. Claude, products of woodturning, bric-a-brac and diamond polishing, all of which are carried on in many small ateliers and shops. The demands for electricity of these numerous small consumers, who had been using hand, steam or water power, caused the Union Electrique to install a water power plant, which has recently been completed and occupies a station on the right bank of the Ain in the vicinity of Sant Mortier.

The Ain is a small river which rises in the Jura and has a tortuous but swift course through a rocky country to its juncture with the Rhone. Like all mountain streams, the water flow of the Ain varies greatly with the season. In low water the volume is 14 cu. ft. per second, while at high water it is 25 cu. ft. At Saint Mortier, with a fall of 62 ft., this latter flow would only give a horsepower of 600, which would, of course, have been insufficient. For this reason Lake de Chalain, 28 miles up the river, was tapped for the additional volume of water needed. This lake has an acreage of 5,014 and a depth of 111.5 ft. Its bottom is 104 ft. higher than the river Ain at this point, and an underground tunnel through alluvial earth, of a length of three-quarters of a mile connects the two, piercing the side of the lake. Lake de Chalain is a natural reservoir fed by springs and small streams and its level varies about 32 ft. during the year. It has a capacity of 70,000,000 cu. ft. and furnishes a flow of 565 cu. ft. per second, the year around. Thus the normal volume, if utilized, at the Sant Mortier power house, where the fall is 60.3 ft., would produce 3,000 hp; 2,500 hp is the minimum and this is at a fall of 43.5 ft. during high water, when the loss would be larger but for the equalization caused by a greater volume of water.

All the concrete work and excavation, including the canal, tunnel and plant building was done by M. Yoanny. The turbines were manufactured by Piccard, Pistet & Co., of Geneva, while the entire electric installation, including the distributing system, was furnished by the Maschinenfabrik Oerlikon.

As stated above, an underground tunnel connects the lake and the river and the flow of this tunnel is regulated by sluices near the lake. The smaller river is dammed in a narrow defile, 174 ft. wide, by a concrete dam 33 ft. high and 110 ft. in width at the top, with a slope against the water of 1 to 10, so that the greatest water pressure is only 85 pounds per sq. in. This dam rests upon solid rock. On the right side of the dam are three sluices for admitting water to the supply canal, while on the other side of the dam is a driftwood canal 754 ft. long, parts of it of half tunnel section blasted in the rock of the mountain. It is 36 ft. wide and has a pitch of 1 to 25.
